**Conclusion:** QW ALBI may become a simpler and effective therapeutic option in T2D inadequately controlled on basal insulin to improve glucose control with a lower risk of hypoglycemia and significant and persistent weight loss vs thrice daily LIS.

**The effect of GLP-1 on food intake is lost in trunkally vagotomised participants**

S. Veedefald<sup>1,2</sup>, A. Plamboeck<sup>1,3</sup>, C.F. Deacon<sup>3</sup>, A. Wettergren<sup>2</sup>, L.B. Svendsen<sup>2</sup>, S. Meisner<sup>4</sup>, C. Hovendal<sup>5</sup>, J.J. Holst<sup>3</sup>, T. Vilsbøll<sup>1</sup>, F.K. Knop<sup>1</sup>;

<sup>1</sup>Diabetes Research Division, Department of Internal Medicine, Gentofte Hospital, University of Copenhagen, Hellerup, <sup>2</sup>Department of Surgical Gastroenterology and Liver Transplantation, Rigshospitalet, University of Copenhagen, <sup>3</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, Department of Biomedical Sciences, Panum Institute, University of Copenhagen, <sup>4</sup>Department of Surgical Gastroenterology, Bispebjerg Hospital, University of Copenhagen, <sup>5</sup>Department of Surgical Gastroenterology, Odense University Hospital, University of Southern Denmark, Hellerup, Denmark.

**Background and aims:** The rapid degradation of glucagon-like peptide 1 (GLP-1) by dipeptidyl peptidase 4 (DPP-4) suggests that endogenous GLP-1 may act locally possibly via the vagus nerve before being degraded. We aimed to evaluate the effect of exogenous GLP-1 on plasma glucose (PG), gastric emptying (GE), insulin secretion and food intake in vagotomised participants.

**Materials and methods:** Ten trunkally vagotomised participants (treated for duodenal ulcer) with pyloroplasty (70±2 years (mean±SEM); fasting PG (FPG): 5.7±0.1 mmol/l), and 10 controls (67±1 years; FPG: 5.5±0.1 mmol/l) received 300-min infusions of GLP-1 (1.2 pmol×kg<sup>−1</sup>×min<sup>−1</sup>) or saline on separate days. A fixed liquid meal containing paracetamol was ingested at t=30 min, and an *ad libitum* meal was served at t=240 min.

**Results:** In vagotomised participants, GLP-1 lowered PG only at t=60 min (9.5±1.0 vs. 7.4±1.0 mmol/l, *p*<0.05) whereas it reduced postprandial PG levels below baseline in controls (5.4±0.1 vs. 4.2±0.2 mM, *p*<0.0001). GE was accelerated in vagotomised participants compared to controls (paracetamol T<sub>max</sub>: 71±16 vs. 152±7 min, *p*<0.001) on the saline day. GLP-1 decreased GE in both groups (paracetamol T<sub>max</sub>: 87±17 vs. 222±5 min, *p*<0.0001), albeit to a lesser extent in vagotomised participants. Insulin secretion was unaffected by GLP-1 in vagotomised participants whereas it was suppressed in controls (due to inhibition of GE by GLP-1). GLP-1 reduced *ad libitum* food intake (367±37 vs. 318±29 g, *p*<0.05) in controls but had no effect in the vagotomised group (249±31 vs. 246±44 g, *p*=NS).

**Conclusion:** The effect of GLP-1 on plasma glucose, gastric emptying, and food intake is diminished in vagotomised participants. This could indicate that the effects of GLP-1 on gastric emptying and food intake are mediated via vagal innervation.

**Effect of Roux en-Y gastric bypass and sleeve gastrectomy on glucose metabolism and gut hormone release**

M. Nannipieri<sup>1</sup>, S. Baldi<sup>1</sup>, B. Astiarraga<sup>1</sup>, A. Mari<sup>2</sup>, M. Anselmino<sup>3</sup>, D. Guarino<sup>1</sup>, R. Berta<sup>3</sup>, E. Barsotti<sup>1</sup>, E. Ferrannini<sup>1</sup>;

<sup>1</sup>Internal Medicine, University of Pisa, <sup>2</sup>Bio-Engineering, CNR of Padua,

<sup>3</sup>Bariatric Surgery, Azienda Ospedaliera Universitaria of Pisa, Italy.

**Background and aims:** In morbidly obese patients with type 2 diabetes (T2DM), Roux-en-Y-Gastric-Sypass (RYGB) and Sleeve Gastrectomy (SLV) restore euglycemia after surgery, but the effects on gut hormone release are not completely understood. To evaluate the effects of RYGB and SLV on post-prandial glucose metabolism and gastro-intestinal hormone secretion after an oral MMT in severe obese T2DM patients.

**Materials and methods:** 21 obese T2DM subjects (12 RYGB and 9 SLV) were studied before, 15-d and 1-year after surgery by comparing the response to a MMT preceded by a week of low-calorie intake. β-cell function was assessed by modeling analysis of the C-peptide response to MMT. Plasma ghrelin, polypeptide YY (PYY), and glucagon concentrations were measured during MMT.

**Results:** 15-d and 1-y post-surgery, BMI decreased in RYGB and SLV (42.4±5.9 vs 40.7±5.8 vs 29.0±3.8; 47.6±6.1 vs 45.7±5.9 vs 36.5±6.3 kg/m<sup>2</sup>, respectively, *p*<0.0001 vs baseline). Mean glucose improved (8.8±2.2 vs 8.1±2.7 vs 5.5±1.2, 8.8±1.7 vs 6.9±1.7 vs 5.8±1.6 mmol/l, *p*=0.0002 vs base-

line, respectively) and mean insulin decreased ( $177 \pm 64$  vs  $141 \pm 76$  vs  $115 \pm 56$ ,  $247 \pm 130$  vs  $184 \pm 79$  vs  $140 \pm 63$  pmol/l,  $p=0.005$  vs baseline) in RYGB and SLV, respectively.  $\beta$ -cell glucose sensitivity improved early after surgery ( $28.8 \pm 22.9$  vs  $47.9 \pm 35.5$  vs  $43.8 \pm 25.6$  and  $33.0 \pm 30.9$  vs  $48.8 \pm 39.5$  vs  $45.2 \pm 23.2$  pmol·min<sup>-1</sup>·m<sup>-2</sup>·mM<sup>-1</sup>,  $p=0.02$  vs baseline, respectively). Mean area under the curve (AUC) of ghrelin decreased in both surgeries ( $6552 \pm 4828$  vs  $6223 \pm 5283$  vs  $4155 \pm 1588$  and  $7425 \pm 1917$  vs  $6409 \pm 367$  vs  $2250 \pm 844$  pg/ml<sup>2</sup>·min,  $p=0.0008$ , respectively) and mean ghrelin AUC was directly correlated with glucose AUC changes ( $r^2=0.065$ ,  $p=0.03$ ). After surgery, mean PYY AUC increased in both groups ( $19802 \pm 5745$  vs  $26377 \pm 8335$  vs  $37627 \pm 21088$  and  $11835 \pm 4457$  vs  $17067 \pm 2295$  vs  $19868 \pm 10692$  ng/ml<sup>2</sup>·min,  $p=0.02$ , respectively). Mean PYY AUC was inversely correlated with glucose AUC ( $r^2=0.12$ ,  $p=0.002$ ). Glucagon AUC increased early after surgery, but came back to baseline 1-y later ( $21215 \pm 13707$  vs  $29005 \pm 15421$  vs  $16756 \pm 5747$  and  $15947 \pm 7976$  vs  $24776 \pm 10806$  vs  $14334 \pm 4203$  pg/ml<sup>2</sup>·min, respectively).

**Conclusion:** These findings indicate that both RYGB and SLV are associated with similar improvement in glucose metabolism,  $\beta$ -cell function and glucoregulatory hormone secretion. Increased PYY and enhanced ghrelin suppression are not explained with reduced food intake after surgery.

### Short term effects of laparoscopic adjustable gastric banding (LAGB) and Roux-en-Y gastric bypass (RYGB) vs very low calorie diet (VLCD)

A. Iaconelli<sup>1</sup>, M. Gaggini<sup>2</sup>, A. Gastaldelli<sup>2</sup>, G. Mingrone<sup>1</sup>;

<sup>1</sup>Dpt of Internal Medicine, Università Cattolica S. Cuore, Roma,

<sup>2</sup>Cardiometabolic Risk Lab, Institute of Clinical Physiology-CNR, Pisa, Italy.

**Background and aims:** It has been proposed that bariatric surgical procedures could have early weight loss-independent effects on glucose metabolism in obese patients. However, the results could be biased by the low caloric intake in the first days after surgery since very low calorie diet (VLCD) also improves glucose metabolism. Thus, the aims of this study were to evaluate the short term effects (one week) on insulin sensitivity of two different bariatric surgery procedures, i.e., laparoscopic adjustable gastric banding (LAGB) and roux-en-Y gastric bypass (RYGB), and to compare the changes in glucose metabolism observed after surgery vs. results obtained after one week of supervised VLCD in the same patients studied approximately 3 months before surgery.

**Materials and methods:** We studied 20 obese non diabetic subjects ( $13F/7M$ , BMI= $44.1 \pm 0.7$  kg/m<sup>2</sup>) and evaluated insulin sensitivity by hyperinsulinemic-euglycemic clamp ( $40$  mU/min/m<sup>2</sup>) with tracer infusion ( $6,6$ -<sup>2</sup>H<sub>2</sub>-glucose) and beta cell function by IVGTT at the end of the clamp. Subjects were studied on first hospitalization at baseline and after one week of VLCD ( $600$  kcal/day) and then discharged. Approximately 3 months later subjects were re-hospitalized for surgery, LAGB ( $n=10$ ) or RYGB ( $n=10$ ), and re-studied one week after surgical procedure (caloric intake after surgery was similar to first hospitalization). In all three occasions we measured glucose production (EGP), peripheral insulin sensitivity (as glucose disposal normalized by insulin concentration, M/I), hepatic insulin resistance (Hep-IR=EGPxINS), insulin secretion ( $\Delta AUC_{Cpep}/\Delta AUC_{Glucose}$ , from IVGTT at the end of the clamp),  $\beta$ -cell function (disposition index [DI], determined as  $\Delta AUC_{Cpep}/\Delta AUC_{Glucose} \times M/I$ ).

**Results:** After one week of VLCD subjects lost  $-2.1$  kg but without any significant change in either fasting (from  $182 \pm 11$  to  $176 \pm 9$  mg/min) or clamp EGP (from  $21 \pm 8$  to  $26 \pm 5$  mg/min), Hep-IR (from  $26 \pm 3$  to  $25 \pm 4$  mg/kg/min·nM), peripheral insulin sensitivity (M/I from  $4.5 \pm 0.4$  to  $4.9 \pm 0.5$  mg/kg min nM<sup>-1</sup>), or DI (from  $800 \pm 101$  to  $822 \pm 115$ ). On the other hand, one week after surgery we observed a significant decrease in Hep-IR (RYGB:  $-55\%$ ,  $p<0.05$ ; LAGB:  $-29\%$ ,  $p=ns$  vs baseline) and a significant increase in M/I (RYGB:  $+45\%$   $p<0.05$ ; LAGB:  $+20\%$ ,  $p=ns$ ), with a weight loss of  $-5.5$  kg compared to baseline ( $p=ns$  RYGB vs LAGB). No early change was observed in insulin secretion, but RYGB improved hepatic insulin clearance (from  $420 \pm 23$  to  $566 \pm 21$  ml/min kg,  $p<0.05$ ), thus reducing peripheral insulin levels. Insulin clearance did not change after LAGB (from  $454 \pm 35$  to  $455 \pm 35$  ml/min kg,  $p=ns$ ). For this reason, changes in DI ( $+27\%$  vs  $6\%$ ) did not reach statistical significance vs baseline.

**Conclusion:** Early changes in glucose metabolism were mainly due to bariatric surgery per se since one week VLCD did not improve insulin sensitivity. Early metabolic effects of bariatric surgery rely mainly in early improvement of both hepatic and peripheral insulin sensitivity and were more marked in RYGB than in LAGB.

## 585

### The effect of vagal nerve blockade via overdrive stimulation on response to a mixed meal in non-diabetic subjects

M. Sathananthan<sup>1</sup>, S. Ikramuddin<sup>2</sup>, P.D. Giesler<sup>1</sup>, J. Laugen<sup>1</sup>, R.A. Rizza<sup>1</sup>, M. Camilleri<sup>1</sup>, C. Cobelli<sup>3</sup>, A.R. Zinsmeister<sup>1</sup>, A. Vella<sup>1</sup>;

<sup>1</sup>Mayo Clinic, Rochester, USA, <sup>2</sup>University of Minnesota, Minneapolis, USA,

<sup>3</sup>University of Padua, Italy.

**Background and aims:** Bilateral truncal vagotomy is associated with weight loss. It is uncertain if the effects of bariatric surgery on weight are mediated in part by partial or complete disruption of the vagal trunks. Vagal nerve stimulators produce reversible Vagal Nerve Blockade (VNB) and have been used as potential therapy for obesity. This provides the opportunity to directly study the effect of the vagus on glucose metabolism and enteroendocrine secretion.

**Materials and methods:** Nine subjects (BMI of  $37.6 \pm 1.2$  Kg/M<sup>2</sup>, fasting glucose of  $5.7 \pm 0.5$  mmol/l) were studied on 3 occasions - each after a 2 week period during which VNB was activated or inactivated in random order. At the end of each period subjects were studied using a standardized triple-tracer mixed meal consisting of 50g of bacon, 2 scrambled eggs and 75g of Jell-O labeled with [<sup>1-13</sup>C]-glucose. [<sup>6-3</sup>H] glucose was infused intravenously to measure the systemic rate of meal appearance (Meal Ra). Infused [<sup>6-3</sup>H<sub>2</sub>] glucose enabled measurement of endogenous glucose production (EGP) and glucose disappearance (Rd). The meal was also labeled with [<sup>111</sup>In-DTPA] to enable measurement of gastrointestinal transit. Insulin action (Si) and  $\beta$ -cell responsiveness indices ( $\phi$ ) were estimated using the oral minimal model.

**Results:** The analysis focused on differences between VNB activation and inactivation. Fasting Ghrelin concentrations were slightly but not significantly lower when VNB was activated ( $590 \pm 64$  vs.  $623 \pm 71$  pmol/l, ON vs. OFF respectively,  $p=0.09$ ). No differences in Ghrelin concentrations were apparent after meal ingestion. Integrated glucose ( $184 \pm 66$  vs.  $232 \pm 75$  mol,  $p=0.24$ ), insulin ( $27.5 \pm 5.2$  vs.  $28.9 \pm 3.0$  nmol,  $p=0.52$ ) and glucagon ( $24.1 \pm 3.3$  vs.  $22.7 \pm 2.3$   $\mu$ mol,  $p=0.27$ ) concentrations did not differ between study days. Fasting EGP, suppression of postprandial EGP and integrated Rd also did not differ (table). Interestingly, peak Meal Ra was higher ( $59.8 \pm 2.6$  vs.  $67.3 \pm 2.1$   $\mu$ mol/kg/min,  $p=0.03$ ) when VNB was turned off. No difference in the time taken to empty 10% ( $GE_{10}$ ) and 50% ( $GE_{50}$ ) of stomach contents. Gastrointestinal transit at 24 hours ( $GC_{24}$ ) was also unchanged (table).

**Conclusion:** We conclude that VNB by overdrive stimulation at the level of the cardia alters peak Meal Ra (perhaps by altering fasting gastric volume) but has no direct effects on subsequent gastrointestinal transit, Ghrelin concentrations, glucose metabolism or insulin secretion and action.

	GE <sub>10</sub> (min)	GE <sub>50</sub> (min)	GC <sub>24</sub>	Fasting EGP ( $\mu$ mol/kg/ min)	EGP Suppression (%)	Integrated Rd (Mol per 6hr)

### Glucose homeostasis and incretin hormones one year after bariatric surgery in patients with type 2 diabetes mellitus and obesity

G. Nasso<sup>1</sup>, P.P. Cutolo<sup>2</sup>, M. Cotugno<sup>1</sup>, G. Saldalamacchia<sup>1</sup>, R. Lupoli<sup>1</sup>, E. Griffo<sup>1</sup>, G. Vitagliano<sup>1</sup>, G. Riccardi<sup>1</sup>, L. Angrisan<sup>2</sup>, B. Capaldo<sup>1</sup>;

<sup>1</sup>Department of Clinical and Experimental Medicine, University Federico II,

<sup>2</sup>General and Laparoscopic Surgery Unit, San Giovanni Bosco Hospital, Naples, Italy.

**Background and aims:** Bariatric surgery (BS) improves glucose homeostasis in patients with T2DM and obesity. Aim. To evaluate insulin sensitivity, insulin secretion and incretin hormones in patients with T2DM and severe obesity who had undergone laparoscopic gastric bypass (GB) or sleeve gastrectomy (SG).

**Materials and methods:** In 32 T2DM obese patients [14 operated of GB (6 M;  $48 \pm 9$  years  $43 \pm 6$  Kg/m<sup>2</sup>, M $\pm$ SD) and 18 of SG (8 M;  $44 \pm 10$  years;  $47 \pm 8$  Kg/m<sup>2</sup>)] we evaluated insulin sensitivity and insulin secretion by OGTT and incretin response to a mixed meal before and 1 year after BS.

**Results:** At 1 year, weight loss was similar (~ 30%) and 70% of patients in both groups experienced T2DM remission (fasting plasma glucose < 100 mg/dl and HbA<sub>1c</sub> < 6.0 % in the absence of hypoglycemic therapy). Insulin sensitivity (OGIS index) increased by 53% (from 306 ± 92 to 653 ± 221 ml min<sup>-1</sup>m<sup>-2</sup>, p=0.04) after GB and by 57% (from 346 ± 99 to 539 ± 543 ± 112 ml min<sup>-1</sup>m<sup>-2</sup>, p=0.05) after SG. Insulin secretion (Insulinogenic index) significantly increased in both groups (from 0.58 ± 0.09 to 1.2 ± 0.54 ng/mmol, p=0.05 in GB; from 0.47 ± 0.06 to 1.5 ± 0.6, p=0.04 in SG). GLP-1 peak after mixed meal, rather flat in all subjects preoperatively, doubled 1 year after GB (GLP1<sub>130-Ln</sub> from 1.7±0.9 to 3.6±0.7 pM/L BG, p=0.0001) while it remained substantially unchanged after SG (from 1.2±0.5 to 1.8±0.6 pM/L, p=0.13); in contrast, GIP did not change either after GB or after SG.

**Conclusion:** Insulin secretion and insulin sensitivity improved to the same extent with the two interventions, while GLP-1 profile improved only after GB. These data indirectly support the predominance of mechanisms other than incretin release in the remission of T2DM after GB or SG.

## 587

### Fibroblast growth factor 19 (FGF19) is regulated by gastric bypass and mimics the metabolic benefits after the surgery

A.M. DePaoli<sup>1</sup>, L. Ling<sup>1</sup>, D.D. Kaplan<sup>1</sup>, M. Saberi<sup>1</sup>, P. Zhang<sup>1</sup>, D. Lindhout<sup>1</sup>, S. Gao<sup>1</sup>, H. Yang<sup>1</sup>, M. Zhou<sup>1</sup>, L.E. Davidson<sup>2</sup>, S.C. Hunt<sup>2</sup>, T.D. Adams<sup>2</sup>, H. Tian<sup>1</sup>; <sup>1</sup>NGM Biopharmaceuticals, South San Francisco, <sup>2</sup>University of Utah, Salt Lake City, USA.

**Background and aims:** The gastric bypass (GB) procedure leads to acute remission of type 2 diabetes (T2D) in many patients before significant weight loss. This metabolic improvement is heralded by both an increase in insulin secretion, perhaps explained in part by GLP-1, and an improvement in insulin sensitivity, at this point unexplained. Our goal has been to discover genes that explain the observations of rapid improvement in glucose homeostasis and long term alterations in body weight that could provide a potential approach to mimicking the beneficial effects of the GB procedure.

**Materials and methods:** (1) Microarray and quantitative RT-PCR analyses were performed using RNA extracted from segments of intestines from Zucker Fatty rats following duodenal-jejunal bypass (DJB) or sham surgery. (2) Serum FGF19 levels were determined in 31 T2D patients preoperatively, and 7 days and 21 days following Roux-en-Y gastric bypass (RYGB) or gastric banding bariatric surgery. (3) Glucose, body weight, serum insulin levels and insulin sensitivity were also determined after FGF19 delivery in *db/db*, diet-induced obese (DIO), *ob/ob* and TALLYHO mice, as well as spontaneously obese and insulin resistant cynomolgus monkeys.

**Results:** (1) FGF15 (murine ortholog of FGF19) was identified as significantly regulated at the mRNA level through a systematic gene expression study of Zucker Fatty rats following DJB, a weight-neutral GB procedure. After surgery, FGF15 mRNA is up-regulated by >150% in the ileum as compared to sham-operated rats. (2) FGF19 fasting and fed levels were significantly increased in obese patients with diabetes at 7 and 21 days post GB compared to their preoperative baseline before surgery. (Figure). (3) FGF19 administration in rodent models of diabetes and obesity led to significantly reduced or normalized glucose in DIO, *ob/ob*, *db/db* and TALLYHO mice. Glucose tolerance was assessed in DIO and *ob/ob* mice with an oral glucose load and was significantly improved (similar to GLP-1). A reduced body weight was seen in DIO and *ob/ob* mice, but not in *db/db* and TALLYHO mice. FGF19 demonstrated a significant improvement in hepatic insulin sensitivity in a euglycemic hyperinsulinemic clamp study in *db/db* mice. (4) Daily subcutaneous administration of FGF19 to spontaneously obese, insulin resistant cynomolgus monkeys led to a rapid improvement in insulin sensitivity independent of weight loss.

**Conclusion:** FGF19 is a secreted GI hormone that is regulated by gastric bypass and may mediate some of the metabolic improvements and sustained body weight loss seen with the GB procedure. Further study of this pathway as a potential therapeutic approach to T2D seems warranted.

## 588

### Hepatic and peripheral insulin sensitivity 1 week and 3 months after Roux-en-Y gastric bypass surgery in subjects with type 2 diabetes and normal glucose tolerance

K.N. Bojsen-Møller<sup>1</sup>, C. Dirksen<sup>1</sup>, S.H. Jacobsen<sup>1</sup>, N.B. Jørgensen<sup>1</sup>, A.K. Serup<sup>2</sup>, D.L. Hansen<sup>1</sup>, D. Worm<sup>1</sup>, J.J. Holst<sup>3</sup>, E.A. Richter<sup>2</sup>, S. Madsbad<sup>1</sup>; <sup>1</sup>Department of Endocrinology, Hvidovre Hospital, <sup>2</sup>Department of Exercise and Sport Sciences, University of Copenhagen, <sup>3</sup>Department of Biomedical Sciences, University of Copenhagen, Denmark.

**Background and aims:** Roux-en-Y gastric bypass (RYGB) improves glucose metabolism in type 2 diabetes (T2D) within days after surgery but whether early changes in insulin sensitivity are part of the physiological mechanism is not known.

**Materials and methods:** We studied 9 obese subjects with T2D (BMI: 38.1±1.8 kg/m<sup>2</sup> (mean ± sem), HbA<sub>1c</sub>: 7.1±0.4%) and 10 obese subjects with normal glucose tolerance (NGT) (BMI: 40.2±0.8 kg/m<sup>2</sup>, HbA<sub>1c</sub>: 5.4±0.1%) before, 1 week (wk) after and 3 months (mo) after RYGB using 4 hours hyperinsulinemic (40 mU/m<sup>2</sup>/min) euglycemic (5.5 mmol/l) clamp combined with infusion of [6,6-<sup>2</sup>H<sub>2</sub>]-glucose to assess hepatic glucose production (HGP). Fat free mass (ffm) was assessed by whole body DEXA scan.

**Results:** Fasting glucose levels decreased in both groups at 1 wk and remained lower after 3 mo (T2D: 8.5±0.8, 6.8±0.4 p=0.05, 5.9±0.3 mmol/l p=0.05; NGT: 5.1±0.1, 4.8±0.2 p=0.02, 4.6±0.1 mmol/l p<0.01). HOMA-IR was significantly reduced in both groups at 1 wk and 3 mo (T2D: 5.2±0.9, 3.9±1.0 p=0.04, 1.7±0.3 p=0.05; NGT: 2.8±0.4, 1.7±0.2 p=0.01, 0.9±0.1 p<0.01). Basal HGP decreased 1 wk after RYGB in T2D (3.7±0.4, 3.0±0.2 mg/kg<sub>ffm</sub>/min p=0.05) whereas no significant change was observed in NGT (3.2±0.3, 2.8±0.1 mg/kg<sub>ffm</sub>/min p=0.25). Peripheral insulin sensitivity measured by M<sub>ffm</sub>/I was unchanged 1 wk after RYGB in both groups but improved at 3 mo (T2D: 11.1±2.2, 14.7±2.8 p=0.09, 24.4±3.6 g/kg<sub>ffm</sub>/min/pmol/l p=0.03; NGT: 18.7±2.8, 16.2±1.6 p=0.16, 27.9±3.0 g/kg<sub>ffm</sub>/min/pmol/l p=0.02) at which time weight loss was 14.0±0.9% (p<0.01) in T2D and 17.5±1.9% (p<0.01) in NGT.

**Conclusion:** Decreased hepatic glucose production was observed 1 wk after RYGB in T2D explaining the early reduction in fasting glucose. Peripheral insulin sensitivity did not improve prior to weight loss but was evident at 3 mo postoperatively. RYGB may have differential effects on tissue insulin sensitivity with early improvements in hepatic insulin sensitivity and later weight-loss dependent improvements in peripheral insulin sensitivity.

#### Elevated mitochondria biogenesis in skeletal muscle is associated with testosterone-induced weight loss

K. Kajita<sup>1</sup>, T. Usui<sup>1</sup>, K. Fujioka<sup>1</sup>, I. Mori<sup>1</sup>, T. Hanamoto<sup>1</sup>, T. Ikeda<sup>1</sup>, H. Okada<sup>1</sup>, K. Taguchi<sup>1</sup>, Y. Uno<sup>1</sup>, H. Morita<sup>1</sup>, M. Shimpuku<sup>2</sup>, T. Sasaki<sup>2</sup>, T. Kitamura<sup>3</sup>, I. Kojima<sup>2</sup>, T. Ishizuka<sup>1</sup>;

<sup>1</sup>General Internal Medicine, Gifu University Graduate School of Medicine,

<sup>2</sup>Institute for Molecular and Cellular Regulation, Gunma University,

Maebashi, <sup>3</sup>General Internal Medicine, Institute for Molecular and Cellular Regulation, Gunma University, Maebashi, Japan.

**Background and aims:** Numerous clinical observations have revealed that low serum testosterone level is associated with male obese or type 2 diabetic patients. These results suggest that testosterone prevents obesity in men. Recently, we found that feeding with food containing 0.4% DHEA or testosterone (T) equally decreases body weight and fat weight without affecting food consumption in rats. Moreover, DHEA or T treatment similarly decreases PPAR $\gamma$ , lipoprotein lipase and adiponectin mRNA levels in 3T3-L1 adipocytes, however these treatment did not influence lipolysis and expression levels of SREBP-1 and fatty acid synthase. These results suggest that reduced adiposity by DHEA or T cannot be explained by increased lipolysis and suppressed triglyceride production in adipocyte. Therefore, possible mechanism is increased energy expenditure. In this study, we examined the effect of T on mitochondrial heat production, since little is known about the effect of androgen on mitochondria biogenesis, especially in skeletal muscle.

**Materials and methods:** C57/black mice were housed with or without 0.4% T containing food for 4w, and then O<sub>2</sub> consumption and CO<sub>2</sub> production were measured by indirect calorimetry. Expression of PPAR $\gamma$  coactivator 1 $\alpha$  (PGC1 $\alpha$ ) and mitochondrial protein ATP5B, Cox 4 and cytochrome c levels in various organ were measured with western blot and real time RT-PCR. In addition, effect of T on amount of mitochondria in C2C12 myotube was accessed with Rhodamine 123.

**Results:** Treatment with T significantly decreased body weight and fat weight in C57/black mice, whereas food consumption was not changed. O<sub>2</sub> consumption during 24 hr and light(resting) phase was significantly elevated in the treated mice, while locomotor activity was significantly lower in the treated group. Respiratory quotients, the ratio: eliminated CO<sub>2</sub>/consumed O<sub>2</sub>, were not changed in the treated mice compared with control. These results indicated that testosterone-induced weight loss due to the increased energy expenditure. Furthermore, the fact that O<sub>2</sub> consumption increased despite of decreased locomotor activity indicates that testosterone administration raises basal metabolic rate. Treatment with T increased protein level of PGC1 $\alpha$  in brown adipose tissue (BAT) and skeletal muscle, but not in white adipose tissue and liver. The expression levels of ATP5B and Cox 4 were increased in skeletal muscle by the treatment. Although T increased the expression levels of ATP5B and Cox 4 in BAT, the change was not significant. Treatment with 10 nM T increased the expression level of PGC1 $\alpha$  mRNA, Cox 4 protein level and staining levels with Rhodamine 123 in a concentration depending manner in C2C12 myotube. Since PGC1 $\alpha$  is a key regulator of mitochondrial biogenesis, T-induced upregulation of PGC1 $\alpha$  may lead to increase mitochondrial specific protein levels especially in skeletal muscle.

**Conclusion:** T-induced weight loss is associated with increased basal metabolic rate, which may be explained by the increased PGC1 $\alpha$  expression and mitochondrial biogenesis in skeletal muscle.

#### Impaired insulin-/IGF1-signalling extends life span by promoting mitochondrial L-Proline catabolism to induce a transient ROS-signal

K. Zarse<sup>1</sup>, S. Schmeißer<sup>1,2</sup>, M. Groth<sup>3</sup>, S. Priebe<sup>4</sup>, G. Beuster<sup>1</sup>, D. Kuhlow<sup>1,5</sup>, R. Guthke<sup>4</sup>, M. Platzer<sup>3</sup>, C.R. Kahn<sup>6</sup>, M. Ristow<sup>1,5</sup>;

Jena, <sup>5</sup>Dept. of Clinical Nutrition, German Institute of Human Nutrition

Potsdam-Rehbrücke, Nuthetal, Germany, <sup>6</sup>Section on Integrative Physiology

and Metabolism, Joslin Diabetes Center, Harvard Medical School, Boston, USA.

**Background and aims:** In mammals, impaired insulin like growth-factor 1 and insulin signaling (iIS) is linked to several chronic diseases, including type 2 diabetes, cancer and neurodegeneration, whereas in the well-characterized model organism *C. elegans*, reduced iIS due to impaired expression of daf-2 (mammalian insulin-/IGF-1-receptors orthologue), extends life expectancy by more than two-fold. In the present study, we address the hypothesis that iIS induces oxidative nonglucose metabolism and generates a reactive oxygen species (ROS) imbalance which in turn is instrumental for the life span-extending capabilities of iIS in *C. elegans*.

**Materials and methods:** We analyzed three different models of iIS: a (I) *C. elegans* strain carrying a mutant daf-2(e1370) gene, as well as mammalian fibroblasts either (II) homozygously deficient for the insulin receptor substrate 1 (IRS1) or (III) heterozygously deficient for the insulin receptor.

**Results:** We show here that chronically iIS increases mitochondrial activity, but also unexpectedly reduces ROS levels. By contrast, RNAi-mediated knockdown of daf-2 in adult *C. elegans* not only impairs glucose metabolism, but also permanently increases mitochondrial activity and transiently increases ROS levels. Consistent with the concept of mitochondrial hormesis (mitohormesis), this latter ROS increase causes an adaptive response by inducing the activities of endogenous ROS-defense enzymes, superoxide dismutase and catalase, which culminates in increased stress resistance and ultimately reduces ROS levels despite constitutively increased mitochondrial activity. Inhibition of this ROS signal by different exogenous antioxidants reduces the life-extending capability of daf-2 impairment by up to 60%. Generation of this transient ROS signal was found to depend on AAK-2 (AMPK analogue), while PMK-1 (p38 MAP kinase) and SKN-1 (NRF-2 analogue) are required for ROS sensing to exert the retrograde response to the acute knockdown of daf-2. Lastly, transcriptome analyses identified mitochondrial L-proline catabolism to be uniformly upregulated in all three models of iIS studied, and impairment of L-proline catabolism in nematodes reduces the life span extending capacity of iIS while L-proline supplementation extends *C. elegans* life span.

**Conclusion:** Taken together, our results indicate that impaired iIS causes oxidative low-glucose L-proline metabolism which employs ROS as signaling molecules for the adaptive induction of endogenous stress defense to promote longevity.

#### Overexpression of the adiponectin receptor AdipoR1 in rat skeletal muscle amplifies local insulin sensitivity

M.E. Cleasby<sup>1,2</sup>, K.L. Hoehn<sup>3</sup>, S.A. Patel<sup>1</sup>, R.T. Lawrence<sup>3</sup>, L. Sawbridge<sup>1</sup>, N.A. Talbot<sup>1</sup>, N. Turner<sup>2</sup>, G.J. Cooney<sup>2</sup>, J.P. Whitehead<sup>4</sup>, E.W. Kraegen<sup>2</sup>;

<sup>1</sup>Comparative Biomedical Sciences, Royal Veterinary College, London, UK,

<sup>2</sup>Diabetes and Obesity Program, Garvan Institute of Medical Research,

Sydney, Australia, <sup>3</sup>Department of Pharmacology, University of Virginia

Health System, Charlottesville, USA, <sup>4</sup>Metabolic Medicine, Mater Medical

Research Institute, Brisbane, Australia.

**Background and aims:** Adiponectin is a multimeric adipokine whose plasma levels are reduced in insulin resistant or obese humans or animals. Its effects are mediated through binding to receptors, of which adiponectin receptor 1 (AdipoR1) is the most abundant in skeletal muscle. Adiponectin has direct effects on rodent skeletal muscle strips to enhance glucose disposal and mitochondrial oxidation, and these effects are impaired in strips from high fat diet (HFD)-fed animals. However, the *in vivo* significance of altered adiponectin sensitivity and the molecular mechanisms of the putative muscle insulin sensitising action of adiponectin have not been fully established.

**Materials and methods:** *In vivo* electrotransfer was used to overexpress AdipoR1 in single *tibialis cranialis* (TC) muscles of otherwise untreated rats and also in six week chow or HFD-fed rats which were subsequently subjected to hyperinsulinaemic-euglycaemic clamp. After one week, the effects on glucose disposal (radioactive tracer methodology), intracellular signalling (western blotting) and sphingolipid metabolism (GC-MS and qPCR) were investigated in test versus paired control muscles (n=6–15). Data were analysed using paired t-test or two-way ANOVA with repeated measures, as appropriate.

**Results:** AdipoR1 was overexpressed 5.5-fold ( $p<0.001$ ) in basal rat TC muscles, which resulted in a 17% increase in glycogen content ( $p=0.011$ ) and increased phosphorylation of IRS1 (Tyr612, 41%,  $p=0.006$ ), Akt (Ser473, 34%,  $p=0.003$ ) and GSK3 $\beta$  (Ser9, 21%,  $p=0.030$ ). AdipoR1 was overexpressed ~3-fold in both clamped chow and HFD-fed rats, which resulted in increased insulin-stimulated glucose uptake ( $p=0.039$ ), glycogen synthesis ( $p=0.009$ ) and glycogen content ( $p<0.001$ ) in muscles of both feeding groups, implying local amelioration of the HFD-induced defect in glucose disposal. This was associated with increased phosphorylation of IRS1 ( $p<0.001$ ), Akt ( $p=0.015$ ) and GSK3 $\beta$  ( $p=0.004$ ). AdipoR1 overexpression (OE) also caused increased phosphorylation (activation) of AMP-activated protein kinase (pT172,  $p<0.001$ ) and its target acetyl coA carboxylase (pS79,  $p=0.050$ ), as well as increased protein levels of PGC1 $\alpha$  ( $p<0.001$ ) and UCP3 ( $p<0.001$ ), indicative of increased mitochondrial biogenesis and oxidation. Although neither HFD-feeding nor AdipoR1 OE caused generalised changes in sphingolipids, including ceramides, AdipoR1 OE did reduce levels of sphingosine 1-phosphate ( $p=0.011$ ), ceramide 18:1 ( $p=0.020$ ), ceramide 20:2 ( $p=0.031$ ) and dihydroceramide 20:0 ( $p=0.036$ ), plus mRNA levels of the ceramide synthetic enzymes ceramide synthase-1 ( $p=0.003$ ), serine palmitoyl transferase ( $p=0.022$ ) and sphingolipid delta-4 desaturase ( $p=0.027$ ).

**Conclusion:** This study demonstrates that therapeutic targeting of improved adiponectin sensitivity may be beneficial in the treatment of IR in muscle. The insulin sensitising effect of adiponectin in muscle involves an additive effect on PI3-kinase signalling and enhanced mitochondrial function, which may be mediated through selective reductions in sphingolipid species.

### Dissociation between *in vivo* and *in vitro* muscle mitochondrial function in patients with type 2 diabetes

C. Brøns<sup>1</sup>, B. Mortensen<sup>2</sup>, K. Pilgaard<sup>2</sup>, K. Rasmussen<sup>1</sup>, P. Poulsen<sup>3</sup>, A. Vaag<sup>1</sup>, B. Quistorff<sup>4</sup>

<sup>1</sup>Rigshospitalet, Copenhagen, <sup>2</sup>Steno Diabetes Center, Gentofte, <sup>3</sup>Novo Nordisk A/S, Bagsvaerd, <sup>4</sup>University of Copenhagen, Denmark.

**Background and aims:** The role of mitochondrial dysfunction in the development of muscle insulin resistance in Type 2 diabetes (T2D) is controversial, and may depend on whether the mitochondrial function is determined *in vivo* or under *in vitro* conditions. In this study, we aimed to measure and compare *in vivo* and *in vitro* mitochondrial function in T2D subjects and in a control group of normoglycaemic healthy subjects.

**Materials and methods:** Twelve middle-aged, obese men with T2D (mean age  $54.2 \pm 1.14$  years, BMI  $31.4 \pm 1.37$  kg/m<sup>2</sup>) and 8 matched non-diabetic control subjects (mean age  $55.3 \pm 2.51$  years, BMI  $29.4 \pm 1.06$  kg/m<sup>2</sup>) participated in the study. The T2D patients were instructed to discontinue all medication 24 hours prior to the investigation. A standard OGTT was performed, and mitochondrial function was assessed *in vivo* by <sup>31</sup>P Magnetic Resonance Spectroscopy in the wrist/finger flexor and in the tibialis anterior muscles at rest and during recovery after an acute exercise bout. *In vitro* mitochondrial function was measured by respirometry in permeabilized muscle fibers from the tibialis anterior and quadriceps muscles. Statistical analysis was performed using paired and unpaired t-test and Fischers exact test when appropriate. Differences were considered to be statistically significant at a two-sided P-value less than 0.05.

**Results:** The T2D subjects had a higher HbA1c ( $P=0.01$ ) and an increased fasting plasma glucose level ( $P<0.01$ ) compared to the control subjects. The T2D subjects were comparable with respect to age, BMI and standard anthropometric and biochemical analyses. No difference was found between T2D subjects and controls in any measures of *in vivo* mitochondrial function during rest or recovery after acute exercise. However, T2D patients displayed decreased *in vitro* mitochondrial state 3 as well as state 4 respiration ( $P<0.05$ ) in both muscle fibre types compared with the controls. No correlations were found between *in vivo* and *in vitro* measurements of mitochondrial function in T2D subjects or controls.

**Conclusion:** Compensatory mechanisms including increased substrate availability during *in vivo* hyperglycaemic conditions may explain the dissociation between *in vivo* and *in vitro* mitochondrial function in T2D patients compared with controls. Whether impaired *in vitro* mitochondrial function may represent a primary metabolic defect, involved in the development of insulin resistance, or is a protective and thus compensatory down-regulation in T2D subjects due to increased substrate availability remains unknown.

### The mitochondrial target of thiazolidinediones (mTOT): insulin sensitisation through a mitochondrial metabolic switch

W.G. McDonald<sup>1</sup>, G.S. Cavey<sup>2</sup>, S.L. Cole<sup>1</sup>, D.D. Holewa<sup>1</sup>, A.S. Brightwell-Conrad<sup>1</sup>, R.F. Kletzian<sup>1</sup>, J.R. Colca<sup>1</sup>

<sup>1</sup>Metabolic Solutions Development Co., Kalamazoo, <sup>2</sup>Southwest Michigan Innovation Center Core Life Science Lab, Kalamazoo, USA.

**Background and aims:** The thiazolidinediones (TZDs) are insulin sensitizing agents of proven utility in the clinic but their use is compromised by side effects that are driven by PPAR $\gamma$ . A complete understanding of the mechanism of action of these compounds will allow for the development of more useful insulin sensitizers.

**Materials and methods:** We have used a TZD based photoaffinity probe coupled with mass spectrometry-based proteomics to identify a mitochondrial target of insulin sensitizing agents. To determine the degree to which this target is involved in the actions of insulin sensitizers, we have studied the ability of various analogs, including PPAR $\gamma$ -independent TZDs, MSDC-0160 and MSDC-0602, to enhance differentiation of brown adipose tissue (BAT) progenitor cells from genetically modified mice.

**Results:** The identified mitochondrial target (mitochondrial Target of TZDs, mTOT) is part of a phylogenetically conserved complex in the inner mitochondrial membrane, which is responsible for binding of these agents to the mitochondrion. The expression of mTOT is tightly regulated with the expression of another member of the complex, the mTOT-Like protein. Emerging work in yeast and *Drosophila* has suggested that this protein complex is involved with transport of pyruvate into the matrix of the mitochondria. UK5099, a specific pyruvate transport inhibitor, potentially blocks the photoaffinity crosslinking of mTOT. Ablation of the gene encoding mTOT results in embryonic lethality in mice (E11, E12). A targeted mutation that deletes the first 16 amino acids of the amino terminal sequence results in viable animals, however, expression of the mTOT-Like protein is severely depressed in some tissues. Progenitor cells isolated from the axillary adipose tissue from these animals were unable to differentiate in response to TZDs, perhaps due to low expression of mTOT-Like. Additionally, TZD drug action in BAT progenitor cells causes post-translational modifications such as dephosphorylation of mitochondrially associated GSK3 $\beta$ , as well as changes in the lysine acetylation state of a number of mitochondrial proteins.

**Conclusion:** The identified mitochondrial complex, containing both mTOT and mTOT-Like, appears to be involved in the metabolism of pyruvate, which places it at the crossroads of metabolic regulation. Identification of the mTOT target and understanding its role in metabolic signaling provides an alternative approach to discovery of novel, non-TZD insulin sensitizing agents.

## 594

### Muscle transcripts of mitochondrial oxidative metabolism genes associate with fuel selection, but do not respond to testosterone therapy in men with subnormal testosterone

S.J. Petersson, L. Frederiksen, M. Andersen, K. Højlund; Department of Endocrinology, Section for Molecular Diabetes & Metabolism, Odense University Hospital, and Institute of Clinical Research, University of Southern Denmark, Denmark.

**Background and aims:** An association between low serum testosterone levels, low insulin sensitivity and reduced mitochondrial function has previously been identified in men. We have shown that testosterone therapy promotes a shift in fuel selection towards increased lipid oxidation and decreased glucose oxidation as well as a reduction in plasma adiponectin. This study aims to investigate the relationship between muscle transcripts involved in mitochondrial oxidative metabolism and whole-body measurements of insulin sensi-

tivity, glucose and lipid oxidation, as well as the effect of testosterone therapy on these muscle transcripts in men with subnormal testosterone levels.

**Materials and methods:** Skeletal muscle biopsies were obtained from elderly men ( $n=25$ ) with subnormal bioavailable testosterone before and after treatment with either testosterone gel ( $n=12$ ) or placebo ( $n=13$ ) for 6 months. Insulin-stimulated values of glucose disposal (Rd) and estimates of glucose and lipid oxidation in the basal state were assessed by euglycemic hyperinsulinemic clamps combined with indirect calorimetry. Muscle RNA of a selected set of genes involved in oxidative phosphorylation (OXPHOS), tricarboxylic acid cycle (TCA cycle), lipid oxidation and transport, and adiponectin-AMPK signaling was extracted and reverse transcribed, and gene expression was examined by qRT-PCR. Significance levels:  $**p<0.01$  and  $*p<0.05$ .

**Results:** In the total cohort, Rd was not significantly associated with muscle transcripts involved in OXPHOS, TCA cycle or lipid oxidation, but correlated negatively with the AMPK subunit, *PRKAG3* ( $r=-0.56^{**}$ ) and positively with *CPT1B* ( $r=0.50^{*}$ ). Basal glucose oxidation correlated positively with muscle mRNA levels of *NDUFS1* ( $r=0.46^{*}$ ), *SDHA* ( $r=0.51^{**}$ ), *UQCRC1* ( $r=0.65^{**}$ ), *COX5B* ( $r=0.52^{**}$ ), *ATP5A1* ( $r=0.58^{**}$ ), *CS* ( $r=0.43^{*}$ ), *ETFA* ( $r=0.51^{**}$ ), *ACADVL* ( $r=0.45^{*}$ ), *HADH* ( $r=0.47^{*}$ ), and *PPARGC1A* ( $r=0.44^{*}$ ). Basal lipid oxidation showed an inverse relationship with the OXPHOS muscle transcripts *UQCRC1* ( $r=-0.47^{*}$ ), *COX5B* ( $r=-0.46^{*}$ ), *ATP5A1* ( $r=-0.43^{*}$ ), and *PPARGC1A* ( $r=-0.43^{*}$ ). Pretreatment levels of bioavailable testosterone correlated positively with several transcripts (*NDUFS1*, *UQCRC1*, *COX5B*, *ATP5A1* and *ACADVL*;  $r=0.43$ – $0.47$ , all $^{*}$ ). Testosterone therapy had no effect on muscle mRNA levels of genes involved in OXPHOS, TCA cycle or lipid metabolism despite a significant placebo-controlled increase in whole-body lipid oxidation. However, in the testosterone treated group, a decrease in plasma adiponectin was accompanied by down-regulation of *ADIPOR2* (1.2 fold;  $p=0.041$ ). The post-treatment mRNA levels of *PRKAG3* ( $p=0.039$ ) was lower in the testosterone treated group.

**Conclusion:** In elderly men with subnormal testosterone levels, muscle transcripts involved in OXPHOS, TCA cycle and lipid oxidation are not associated with insulin sensitivity, but rather with a high rate of glucose oxidation. However, the shift in fuel selection induced by testosterone treatment was not accompanied by changes in mitochondrial biogenesis, whereas the decrease in plasma adiponectin was accompanied by reduced mRNA levels of one of its receptors.

### An mtDNA mutation in the cytochrome-c oxidase impacts age-related processes in liver and pancreatic islet

J. Niemann, L. Wuchert, J. Schultz, F. Nulle, M. Tiedge, S. Baltrusch, C. Johné; Institute of Medical Biochemistry and Molecular Biology, University Rostock, Germany.

**Background and aims:** The cellular energy homeostasis is crucially dependent upon coordinated function of the mitochondrial respiratory chain. Mutations accumulating during ageing in the mitochondrial genome (mtDNA) directly affect subunits of the respiratory chain complexes and, thus, their assembling and function. Recently, mtDNA mutations were discussed to contribute to the development of type 2 diabetes mellitus. Therefore the aim of this study was to investigate pancreatic islet and liver function in mice carrying a single mtDNA mutation in the cytochrome-c oxidase (complex IV) of the respiratory chain.

**Materials and methods:** Pancreatic islets and liver were isolated from C57BL/6J-mt<sup>NOD</sup> (mtNOD) and C57BL/6J (control) mice. Gene expression was analyzed by quantitative RT-PCR. Mitochondrial morphology was determined by MitoTracker staining. Basal and glucose-induced insulin secretion was analyzed by ELISA.

**Results:** The nt9348 mtDNA variant (mtNOD) resulted in an amino acid change from valine to isoleucine in the subunit 3 of the cytochrome-c oxidase. Cytochrome-c oxidase gene expression in the liver of the mtNOD mice was comparable to controls. At the age of 12 months gene expression of the antioxidative enzyme Cu/Zn SOD was significantly increased in liver of mtNOD and control mice indicating an age-dependent increase in generation of reactive oxygen species (ROS). The gene expression of the uncoupling protein UCP2 and the enzyme pyruvate carboxylase remained unchanged in the liver of 3, 6, and 12 month old control animals. In contrast, there was an age-dependent decrease in the UCP2 expression and a significant increase in the pyruvate carboxylase expression in the liver of mtNOD mice pointing out a positive mitochondrial adaption process. Aggregation and loss of the

homogenous mitochondrial structure was observed during ageing in the liver of mtNOD and control mice. However, in mtNOD mice significant changes of the mitochondrial network structure occurred already at early lifetime between the age of 3 to 6 months. Interestingly, a higher amount of loops and circular structures contributed to the mitochondrial network in hepatocytes from mtNOD mice. Islets from mtNOD mice showed slightly higher glucose-induced insulin secretion compared to controls. At the age of 3 and 6 month basal insulin secretion of mtNOD islets was significantly higher than in controls. In 12 month old animals the basal insulin secretion increased as well in the controls resulting in a comparable secretion.

**Conclusion:** Our data indicate that a single mtDNA mutation in the cytochrome-c oxidase significantly affected the mitochondrial network structure in liver. These morphological changes are partially linked to ROS generation and antioxidative response. The C57BL/6J-mt<sup>NOD</sup> mouse strain represents an interesting model to study trigger effects of age-dependent mitochondrial phenotypes in the pathogenesis of type 2 diabetes mellitus.

## 596

### Age-dependend effects of the ATP8 mutation on mitochondrial gene expression and energy metabolism in liver of conplastic B6-mt<sup>FVB</sup>

F. Nulle, J. Niemann, M. Tiedge, S. Baltrusch, H. Weiss; Insitute of Medical Biochemistry and Molecularbiology, University of Rostock, Germany.

**Background and aims:** The conplastic mouse strain B6-mt<sup>FVB</sup> (FVB) carries a mitochondrial DNA polymorphism in the Atp8 gene coding for the regulatory subunit 8 of the ATP-synthase (nt7778T Asp to Tyr). This mutation resulted in higher ROS production and a pathological mitochondrial phenotype in different tissues compared to the B6-mt<sup>AKR</sup> (AKR) control strain. In this study we investigated age-dependent effects of the Atp8 mutation on mitochondrial gene expression profile, expression of respiratory chain complexes and energy state in the liver.

**Materials and methods:** Liver samples were collected from FVB and AKR mice at the age of 3, 6, 9 and 12 months ( $n = 6$ ). ATP-content was measured by a luminometric assay. The expression of specific mitochondrial genes was quantified by RT-qPCR and RT-PCR Array analyses (Qiagen, Mouse Mitochondria). Protein expression of the respiratory chain complexes and ATP-synthase were quantified by Western Blot analysis.

**Results:** Feeding a standard diet AKR and FVB mice showed comparable age-dependent gain in body weight and normal blood glucose levels. After 3 months ATP-synthase protein expression was higher in liver from FVB mice compared to AKR controls. Protein expression of complex IV showed a significant decrease during aging in FVB and AKR ( $p<0.05$ ) mice. Both strains showed no differences in ATP-content of liver tissue until the age of 6 months. At the age of 9 months a significant 1.8-fold decrease of ATP-content was observed in liver from FVB mice ( $AKR 18 \pm 2 \mu\text{mol/g}$  vs.  $FVB 10 \pm 2.8 \mu\text{mol/g}$ ,  $p < 0.01$ ). At the age of 3 months a higher gene expression of the molecular chaperone aryl-hydrocarbon receptor-interacting protein (Aip) (7-fold), SOD1 (2.4-fold), SOD2 (1.6-fold), UCP2 (2.2-fold), Bcl-2 (1.9-fold), mTOR (2-fold) and ATP-synthase (1.5-fold;  $p<0.05$ ) was observed in liver from FVB mice compared to AKR controls. At the age of 6 months the expression of UCP2 (1.9-fold), mTOR (1.9-fold) and ATP-Synthase (1.7-fold;  $p<0.05$ ) remained higher in FVB compared with AKR mice. After 12 months FVB mice showed a further increase of Aip (8-fold), SOD1 (2.5-fold) and Bcl-2 (3.5-fold) gene expression. In contrast, expression of mitochondrial protein import complexes, namely the protein translocators Timm17a and Timm8a1 and solute carrier transport proteins (Slc25a13/Slc25a5: adenine nucleotide translocator, Slc25a22: glutamate carrier) were significantly down-regulated in the liver from FVB mice at the age of 12 months compared to 3 months.

**Conclusion:** The data indicate that FVB mice with the Atp8 mutation compensated generation of reactive oxygen species in the liver through up-regulation of antioxidative enzymes. In addition the increased expression of the apoptosis-inhibitor factor Bcl-2 during ageing preserved cell viability. Mitochondrial DNA mutations induce mitochondrial adaptation processes during adolescence to guarantee sufficient energy demands of cells. However, at high age compensatory mitochondrial dynamics limits substrate fluxes into the mitochondria with concomitantly lower ATP levels. Thus, conplastic mtDNA mouse strains are ideal models to identify gene signatures of mitochondrial dysfunction that determine susceptibility to metabolic stress and type 2 diabetes at different stages of lifetime.

## PS 039 Exercise: impact and benefits

597

### Epigenetic regulation of muscle plasticity in response to endurance exercise

T. Kanzleiter, H. Vogel, N. Hallahan, M. Jähnert, A. Schürmann; Dife, Nuthetal, Germany.

**Background and aims:** Skeletal muscle accounts for ~50% of energy expenditure and is a major tissue for nutrient oxidation. Muscle plays a key role in insulin-stimulated postprandial glucose disposal and is the main site of lipid oxidation in the body; both processes are known to be impaired in type 2 diabetes. Physical exercise is well known for its beneficial effects on muscle metabolism. Recently it was shown for a panel of five genes that acute exercise can modify DNA-methylation in human skeletal muscle. The aim of our study was to investigate changes in muscle DNA-methylation in response to endurance training of mice on a genome wide level to provide a comprehensive picture of the extent of epigenetic effects.

**Materials and methods:** C57BL/6 mice were exercised (EX) on a motorized treadmill (5 days/week) for 4 weeks with increasing training challenge or remained sedentary (SED). Quadriceps muscles were analysed on Agilent microarrays to provide genome wide data on changes in gene expression. Genome wide DNA-methylation patterns were identified with reduced representational bisulfite sequencing (RRBS). An overlay of differentially expressed and methylated genes was calculated to identify genes with changes in DNA-methylation that result in functional consequences. Candidate genes were verified by RT-PCR and gene specific bisulfite sequencing.

**Results:** A total of 3020 genes showed significant changes in muscle gene expression between the EX and SED group. RRBS identified 461 genes which had significant changes in their CpG-methylation in their putative promoter regions. The overlay revealed 63 genes which showed changes in DNA-methylation AND gene expression suggesting functional consequences of the changes in DNA-methylation. Pathway analysis of the candidate genes revealed pathways involved in muscle growth, inflammation and mitochondrial gene expression.

**Conclusion:** Our data provide compelling evidence that prolonged endurance exercise training results in differential DNA-methylation and expression of genes involved in remodelling of skeletal muscle. This suggests that epigenetic mechanisms contribute to muscle plasticity and might therefore lead to novel strategies of treating impaired muscle metabolism.

### Effects of acute endurance exercise on gene expression in human skeletal muscle: search for putative myokines

M. Catoire<sup>1</sup>, M. Mensink<sup>1</sup>, P. Schrauwen<sup>2</sup>, S. Kersten<sup>1</sup>;

<sup>1</sup>Human Nutrition, Wageningen University, <sup>2</sup>Human Biology, Maastricht University, Netherlands.

**Introduction and aim:** Exercise is known to be a powerful way to prevent and treat type 2 diabetes mellitus. Skeletal muscle is the predominant organ impacted by exercise but many of the metabolic changes induced by exercise may involve the liver. An important question is how exercise- or better skeletal muscle contraction - can alter hepatic function and insulin action. It is hypothesized that myokines play an important role in the cross-talk between skeletal muscle and liver. Since only a few myokines are known so far, identifying unknown myokines might provide valuable information for future research on the pathogenesis and treatment of type 2 diabetes mellitus. The aim of this study was to investigate the effect of acute endurance exercise on gene expression in skeletal muscle, with a focus on potential myokines, and to assess the importance of local and systemic effects of exercise on gene expression in skeletal muscle.

**Methods:** Nine healthy, male subjects (40–60 years) cycled for one hour with one leg at a submaximal rate. The passive leg served as control. Before and after exercising, muscle biopsies were taken from both legs and analyzed with microarray to determine which genes changed in response to exercise. Venous blood samples were taken before, directly after and after 2 hours of recovery.

**Results:** One-legged cycling induced a significant change in 938 genes ( $p < 0.01$ ), of which 674 were significantly upregulated and 264 genes were

downregulated. In contrast, in the control leg only 516 genes changed significantly ( $p < 0.01$ ; 384 upregulated, 132 downregulated). There was an overlap of 285 genes between both legs. Secretome analysis revealed that in the exercising leg 73 genes code for potentially secreted proteins (i.e. CXCL2, CX3CL1, MCP-1, FGF6, VEGFA), among them none of the established myokines (IL-6, IL-8, IL-15, BDNF). Plasma levels of several established and putative myokines were measured and this revealed that ANGPTL4 and MCP-1 showed a significant increase after exercise (ANGPTL4;  $p < 0.05$ ) and after 3 hours of recovery (ANGPTL4, MCP-1;  $p < 0.01$ ). IL-6, IL-8, IL-15, BDNF and VEGFA did not increase during exercise or recovery.

**Conclusion:** Exercise-induced gene expression changes are induced by both systemic and local stimuli. Several putative myokines are identified, in literature linked to processes like angiogenesis, growth, insulin signaling and lipid metabolism. MCP-1 and ANGPTL4 are elevated also in plasma after exercise and therefore could play a role in the cross-talk between muscle and liver. Plasma levels of other putative myokines will be measured (CXCL2, CX3CL1).

### The expression of miRNAs in human muscle tissue is influenced by low physical activity

M.M. Kristensen<sup>1</sup>, J. Bork-Jensen<sup>2</sup>, A. Vaag<sup>2</sup>, F. Dela<sup>1</sup>;

<sup>1</sup>Department of Biomedical Sciences, <sup>2</sup>Rigshospitalet, University of Copenhagen, Denmark.

**Background and aims:** MicroRNAs (miRNAs) are important cellular regulators of gene expression in both health and disease. These 19–25 nucleotide long RNA sequences are expressed endogenously in almost all animal and plant species. Studies have found changes in miRNA levels in muscle and blood in response to training. Elucidating the roles of miRNAs in physically inactive humans is important to understand how sedentarism influences gene expression and potentially insulin resistance. We examined the influence of nine days of bed rest on miRNA expression profiles in human skeletal muscle tissue.

**Materials and methods:** 20 healthy young males were studied before and after bed rest for nine days and after four weeks of retraining. Muscle biopsies (vastus lateralis) were used for RNA extraction and miRNA expression profiling was performed using LNA arrays (Exiqon, Denmark). Linear models for microarray analysis (limma) was used to detect differentially expressed miRNAs using Benjamini and Hochberg's false discovery rate (fdr) adjustment for multiple testing. *In silico* target predictions (Targetscan) were performed to understand the biological implications further.

**Results:** Comparing microarray miRNA expression profiles before and after bed rest, we identified seven differentially expressed miRNAs ( $P_{(fdr)} \leq 0.1$ ) of which three were down-regulated (miR-486-3p, miR-24-2\*, and miR-126) and four were up-regulated (ebv-miR-BART2-5p, miR-1246, miR-21, and miR-1908) after bed rest. Interestingly, none of the miRNAs returned to pre-bed rest levels after the retraining period. Targetscan revealed multiple possible targets for each of the seven differentially expressed miRNAs. Among these were *IRS-1* (insulin receptor substrate 1) being a target of miR-126 as well as *PIK3R1* (phosphoinositide-3-kinase, regulatory subunit 1) being a target of miR-21.

**Conclusion:** We identified seven miRNAs with altered expression levels in response to short term bed rest, and none of them returned to the pre-bed rest values even after four weeks of retraining. Predicted targets of the miRNAs relevant to understanding insulin resistance included *IRS-1* and *PIK3R1*. Ongoing analyses should support these findings and illuminate the relation between these miRNAs and their respective targets. In conclusion, nine days of inactivity induced changes in the expression of miRNAs with relevance to insulin resistance, which in turn were not reversed by four weeks of retraining.

**The effects and physiological mechanisms of free-living interval-walking training on glycaemic control in type 2 diabetes patients: a randomised, controlled trial**K. Karstoft<sup>1</sup>, K. Winding<sup>1</sup>, S.H. Knudsen<sup>1</sup>, B.K. Pedersen<sup>1</sup>, J.S. Nielsen<sup>2</sup>, T.P. Solomon<sup>1</sup>;<sup>1</sup>Faculty of Health Sciences, University of Copenhagen, Rigshospitalet,<sup>2</sup>Department of Endocrinology, Diabetes Research Centre, Odense University Hospital, Denmark.

**Background and aims:** In type 2 diabetes patients, free-living walking training is feasible but shows limited effect upon glycaemic control variables. On the other hand, interval training methods have shown huge improvements in glycaemic control but suffer from lower adherence rates. In this study, we first evaluated the feasibility of free-living walking training in type 2 diabetes patients; secondly, we investigated the effects of interval-walking versus continuous-walking training upon glycaemic control; and thirdly, we assessed the underlying physiological mechanisms of changes in glycaemic control.

**Materials and methods:** Subjects with type 2 diabetes ( $58.7 \pm 1.4$  years,  $29.5 \pm 0.9$  kg/m<sup>2</sup>) were randomized to a control group ( $n=8$ ), a continuous-walking training group ( $n=12$ ), or an interval-walking training group ( $n=12$ ). Training groups were instructed to train 5 sessions per week, 60 minutes per session and were controlled with an accelerometer and a heart rate monitor. Before and after the 4 month intervention, maximal oxygen consumption (VO<sub>2max</sub>) was assessed, glycaemic control was measured using continuous glucose monitoring (CGM), and insulin secretion/sensitivity was measured using a hyperglycaemic clamp ( $5.4$  mmol/l above fasting glucose concentration).

**Results:** Training groups demonstrated high and equal training adherence ( $89 \pm 4\%$ ), and training energy-expenditure and mean training intensity were comparable. VO<sub>2max</sub> was unchanged in the control group and continuous-walking group, but increased in the interval-walking group ( $16 \pm 4\%$ ,  $P<0.05$ ). Glycaemic control (mean CGM glucose levels) worsened in the control group (delta mean CGM glucose =  $1.2 \pm 0.4$  mmol/l,  $P<0.05$ ), whereas mean and maximum CGM glucose levels decreased in the interval-walking training group (delta mean CGM glucose =  $-0.8 \pm 0.3$  mmol/l,  $P=0.05$ , delta maximum CGM glucose =  $-2.8 \pm 0.8$  mmol/l,  $P<0.05$ ). The continuous-walking training group showed no changes in glycaemic control. In the interval walking training group, the insulin sensitivity ( $57 \pm 17\%$ ,  $P<0.05$ ) increased, whereas the insulin secretion did not change ( $3 \pm 6\%$ ,  $P>0.05$ ). The disposition index increased comparable to the insulin sensitivity ( $60 \pm 16\%$ ,  $P<0.05$ ). In the continuous-walking and control group, no changes were seen in any of these parameters.

**Conclusion:** Free-living walking training is feasible in type 2 diabetes patients and interval-walking training is superior to energy-expenditure matched continuous-walking training upon improving glycaemic control. Furthermore, interval-walking induced improvements in glycaemic control seem to be dependent on improvements in insulin sensitivity and increased disposition.

**Effects of high-intensity interval training on glucose and fat metabolism in healthy, sedentary middle aged men**A.M. Savolainen<sup>1</sup>, K.K. Kalliokoski<sup>1</sup>, J.J. Eskelinen<sup>1</sup>, V. Lepomäki<sup>1</sup>, I. Heinonen<sup>1</sup>, K. Virtanen<sup>1</sup>, R. Parkkola<sup>1</sup>, J. Kapanen<sup>2</sup>, J. Knuuti<sup>1</sup>, P. Nuutila<sup>1</sup>, J.C. Hannukainen<sup>1</sup>;<sup>1</sup>Turku PET Centre, University of Turku, Finland, <sup>2</sup>Paavo Nurmi Centre, Turku, Finland.

**Background and aims:** Lifestyle interventions have been shown to improve insulin sensitivity in liver and abdominal adipose tissues in obese patients and in patients with prediabetes or type 2 diabetes mellitus. Recently, two weeks of low-volume, high-intensity interval training (HIT) has been shown to increase whole body insulin sensitivity and glucose metabolism in skeletal muscle. The aim of this study was to investigate whether HIT also affects glucose and fatty acid metabolism in internal organs.

**Materials and methods:** Eight healthy, sedentary, middle aged men (mean  $\pm$  SD, age:  $47 \pm 5$  years; BMI:  $26 \pm 2.9$  kg·m<sup>-2</sup>; VO<sub>2max</sub>:  $34 \pm 4$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) were studied before and after two weeks and six sessions of HIT (4–6 x 30 s all out

sprints on a cycle ergometer with 4 minutes of recovery). Skeletal muscle, liver, pancreas, abdominal subcutaneous and visceral fat tissue insulin stimulated glucose uptake and fasting free fatty acid uptake were measured using FDG and FTHA PET -methods. In addition, muscle, liver and pancreas fat content was assessed with magnetic resonance spectroscopy.

**Results:** Following HIT intervention, VO<sub>2max</sub> increased by 4.7 % (from  $34 \pm 4$  to  $35.5 \pm 4$  ml·kg<sup>-1</sup>·min<sup>-1</sup>, student paired t-test,  $p=0.019$ ). Fasting serum free fatty acid concentration (from  $0.46 \pm 0.14$  to  $0.33 \pm 0.09$  mmol·l<sup>-1</sup>,  $p=0.054$ ) and plasma total cholesterol level (from  $5.4 \pm 0.7$  to  $4.5 \pm 0.6$  mmol·l<sup>-1</sup>,  $p<0.001$ ) decreased. Whole body insulin sensitivity increased by 12 % but without statistical significance ( $39.1 \pm 11.4$  vs.  $43.4 \pm 16.3$  μmol·kg<sup>-1</sup>·min<sup>-1</sup>,  $p=0.22$ ). Although glucose uptake in m. quadriceps femoris increased by 38% (from  $44 \pm 11$  to  $60 \pm 18$  μmol·kg<sup>-1</sup>·min<sup>-1</sup>,  $p=0.004$ ), two weeks of HIT had no influence on glucose uptake in liver, pancreas and abdominal adipose tissues. The results of free fatty acid uptake and MRS studies will be presented in the congress.

**Conclusion:** Two weeks of low-volume high-intensity interval training seems to be an effective method to improve insulin sensitivity in skeletal muscle, but has no effect on glucose metabolism in internal organs in healthy middle aged men. Further studies are needed in patients with prediabetes and type 2 diabetes to understand the role of exercise training in the metabolism of internal organs.

## 602

**Altered response to diet and exercise intervention in early-onset type 2 diabetes**D.J. O'Hanlon<sup>1</sup>, K. Wanic<sup>2</sup>, A. Pazderska<sup>2</sup>, S. Shah<sup>2</sup>, D.E. Cooper<sup>1</sup>, N. Collura<sup>2</sup>, D.J. O'Gorman<sup>1</sup>, J.J. Nolan<sup>3</sup>;<sup>1</sup>School of Health and Human Performance, Dublin City University, Ireland,<sup>2</sup>Metabolic Research Unit, St James's Hospital, Trinity College Dublin,Ireland, <sup>3</sup>Steno Diabetes Centre, Gentofte, Denmark.

**Background and aims:** We have reported that patients with early-onset type 2 diabetes (YT2) are much more insulin resistant, and less responsive to lifestyle and medical interventions than patients with later onset diabetes (OT2). We have found (unpublished data) that YT2 has a different metabolic signature, with higher fasting concentrations of total and several individual fatty acid species than OT2. The aim of this study was to further examine and compare the adaptive responses to lifestyle intervention in YT2 and OT2 subjects.

**Materials and methods:** YT2 and OT2 subjects were recruited for baseline examination, and to participate in a 6 month lifestyle intervention including a reduced-calorie diet ( $-2500$  kcal/week) and exercise training at 70% VO<sub>2max</sub>. Testing included a VO<sub>2max</sub> test to exhaustion, fasting anthropometric measurements (weight, waist circumference, and fat mass using bioelectrical impedance), a muscle biopsy from the vastus lateralis (to examine intrinsic mitochondrial function: state 3 respiration measured by respirometry) blood sampling to examine lipid profile, and an OGTT to measure insulin sensitivity (based on a 2 hour OGTT).

**Results:** We recruited 69 patients for evaluation: 23 YT2 ( $27.9 \pm 0.9$  years) and 46 BMI-matched OT2 patients ( $55.3 \pm 1.2$  years). At baseline, there were no differences between groups in waist circumference, VO<sub>2max</sub>, intrinsic mitochondrial function, or indices of insulin sensitivity. There was no difference in fasting triglyceride concentration, but despite a similar diet, the YT2 patients had higher total cholesterol ( $4.7 \pm 0.2$  vs  $4.2 \pm 0.1$  mmol/l,  $p=0.02$ ), and LDL-cholesterol ( $2.8 \pm 0.2$  vs  $2.2 \pm 0.2$  mmol/l,  $p=0.01$ ). A subgroup of 25 subjects (10 YT2 and 15 OT2) completed the lifestyle intervention, after which only the OT2 group had a significant reduction in fat mass ( $\Delta 3.1 \pm 0.9$  kg,  $p=0.01$ ). Both groups had comparable improvements in VO<sub>2max</sub>. However, a reduction in fasting triglyceride concentration ( $\Delta 0.37 \pm 0.1$  mmol/l,  $p=0.01$ ), and an increase in insulin sensitivity (OGIS-2hr:  $\Delta 47.5 \pm 18.3$  ml/min/m<sup>2</sup>,  $p=0.02$ ), occurred only in the OT2 group.

**Conclusion:** YT2 responds differently to lifestyle intervention than OT2. Despite equal compliance, only OT2 subjects exhibited a reduction in fat mass, with improvements in fasting triglyceride concentration and insulin sensitivity. These observations suggest that metabolic factors contribute to treatment resistance in YT2 patients.

## 603

**Oxidative stress and pro-inflammatory proteins are involved in microalbuminuria after prolonged exercise in normoalbuminuric and normotensive type 1 diabetic runners**M. Rodríguez<sup>1,2</sup>, J. Cejas<sup>2</sup>, M. Cruzado<sup>2</sup>, J. Rodríguez Vitoria<sup>3</sup>, G. Minuchín<sup>3</sup>, G. Esteves<sup>3</sup>, C. Castro<sup>2</sup>;<sup>1</sup>University Hospital, <sup>2</sup>Area of Biological Chemistry, <sup>3</sup>Institute of Endocrinology, Metabolism and Nutrition, National University of Cuyo, Mendoza, Argentina.

**Background and aims:** Oxidative stress and inflammatory mediators are possible mechanisms of increased urinary albumin excretion (UAE) in type 1 diabetes (DM1). Prolonged exercise can increase UAE in diabetics and non-diabetics in a transitory way. It is not known the precise mechanisms of increased UAE in intense exercise and it is unclear whether the administration of antioxidants may have some effect.

**Materials and methods:** We evaluated in 12 runners 6 normoalbuminuric and normotensive DM1 and 6 non DM1 controls (C), total antioxidant state (TAS), monocyte chemoattractant protein (MCP-1) and ultra sensitive C-reactive protein (HS-CRP) before, at the end and 24 hours after finishing a first half marathon of 21km (1st M) and in a second half marathon (2nd M) after receiving vitamins E and C 1 g/d/7 days. Data (mean  $\pm$  SEM) were analyzed with ANOVA and Bonferroni post test.

**Results:** Basal UAE (mg/g) was normal in DM1 and C ( $5.66 \pm 1.2$  vs  $5.16 \pm 2.0$  mg/g  $P$ =ns). Immediately post 1st M there was a significant increase in UAE in both groups, higher in DM1 ( $65.1 \pm 20.7$  vs  $20.0 \pm 2.4$  mg/g  $P$ <0.01) and 24h after values returned to baseline. In the 2nd M vitamin supplement did not alter the behavior of UAE. After the 1st M TAS (mM/L) decreased in both groups ( $P$ <0.01 vs basal) with greater reduction in DM1 ( $0.6 \pm 0.1$  vs  $1.1 \pm 0.1$   $P$ <0.02), however vitamin intake was able to keep the TAS values up to the end of the race and 24h after. We then measure pro-inflammatory proteins. In the 1stM HS-CRP increased after 24h race in both groups, being higher in DM1 ( $5.5$  mg/dL  $\pm 0.9$  vs  $1.7 \pm 0.3$ ). MCP-1 aroused immediately finished the marathon in both groups ( $985.1$  pg/mL  $\pm 107.5$  vs  $710.9 \pm 77.5$ ) and 24h after returned to basal only in control groups. In the 2ndM both pro-inflammatory proteins behaved as in the 1stM.

**Conclusion:** The chronic hyperglycemic state with low antioxidant capacity and augmented MCP-1 and HS-CRP could be involved in higher UAE induced by sustained intense exercise in normoalbuminuric and normotensive DM1. Intake of vitamins E and C improves total antioxidant reserve but does not change UAE or inflammatory markers studied.

**Continuous glucose monitoring in 42 runners with type 1 diabetes during an 18 km distance run in Brazil**R.N. Lamounier<sup>1,2</sup>, W.P. Valadares<sup>1</sup>, G.L.C. Mendes<sup>1</sup>, L.H.L. Cordeiro<sup>1</sup>, A.S. Silva<sup>1</sup>, M.G. Silva<sup>3</sup>, J.M. Couto<sup>1</sup>, C.C. Faria<sup>4</sup>, M.L. Miranda<sup>4</sup>, D.F. Motta<sup>5</sup>, D. Giannella-Neto<sup>6</sup>;<sup>1</sup>Endocrinology, Centro de Diabetes de Belo Horizonte, <sup>2</sup>Endocrinology and Diabetes, Hospital Mater Dei, Belo Horizonte, <sup>3</sup>Cardiology, Centro de Diabetes de Belo Horizonte, <sup>4</sup>Nutrition, Centro de Diabetes de Belo Horizonte, <sup>5</sup>Physiology, University of Minas Gerais (UFMG), Belo Horizonte, Brazil, <sup>6</sup>Gastroenterology, University of Sao Paulo (USP), Brazil.

**Background and aims:** Regular exercise is very important for type 1 diabetes mellitus (T1DM) patients. But can predispose to glucose variation and hypoglycemia. The project “Volta Monitorada de Belo Horizonte” aims to prepare subjects with T1DM to participate in long distance runs. We evaluated the glucose profile with continuous glucose monitoring (CGM), during an 18 km race.

**Materials and methods:** Forty-two subjects performed the race with CGM, in Belo Horizonte, Brazil. According to their treatment, they were classified in 3 groups: CSII ( $n=10$ ); Basal analogs (BA;  $n=22$ ); NPH ( $n=10$ ). All subjects were under intensive insulin regimens. Depending on their velocity in the race, they were divided in high (HP) or Low (LP) performers, if they were above or below the median velocity (MV) for the group. CGM readings were collected 24 h before and 36 h after the race. Capillary blood glucose (BG) was measured at the start, in the middle and at the end of the race. Glucose profile was assessed as a function of their performance and insulin treatment. Exposure to low and high glucose levels were assessed as well as glucose variability according to the CGM data, for the coefficient of variation (CV).

**Results:** Mean age was  $28.8 \pm 8.2$  years and time to finish the race was  $139 \pm 29.4$  min. MV was  $8.03$  (range  $5.48$ – $11.87$  km/h). Average HbA1c was  $7.84 \pm 1.34\%$  (similar between basal treatments). Subjects had been monitored for  $4333.2 \pm 108.8$  min, with  $866.64 \pm 339.25$  readings each one. Average CGM value was  $150.7 \pm 21.6$  mg/dL, similar between all 3 basal treatments as well as it was the exposure to hypo and hyperglycemia with  $32.4 \pm 37.6$  readings below  $54$  mg/dL and  $474.24 \pm 206.44$  readings above  $200$  mg/dL. When comparing BG after 9 km, in relation to the value at the start of the race, the reduction was significantly higher among CSII compared to BA ( $55.4\% \pm 25.4\%$  vs  $16.1\% \pm 46.1\%$ ;  $p=0.01$ ). HP (MV= $10.68$  km/h) subjects had lower glucose values compared to LP (MV= $6.80$  km/h); Median:  $140.7$  vs  $158.28$  mg/dL;  $p=0.03$ ; as well as lower glucose variation according to CV ( $0.39$  vs  $0.50$ ;  $p<0.01$ ). Those with HbA1c  $<7.0\%$  had a better performance than those with HbA1c  $\geq 7.0\%$  (Median:  $9.32$  vs  $7.34$  km/h;  $p<0.01$ ).

**Conclusion:** Among these runners, glucose variability was similar through different basal insulin regimens. The overall low exposure to hypoglycemia observed in this study (4% of the time below  $54$ mg/dL) could suggest a protective role of CGM for T1DM athletes. Interestingly, in the first 9 km the reduction in glucose was deeper in the CSII group, but throughout all the CGM period it was similar, considering the whole race and the CGM time before and after it. Individuals with better physical fit showed better glucose control and lower glucose variation according to CGM, which was in accordance with the observation that those with higher previous HbA1c, had worse athletic performance. This data suggests that among these T1DM runners, the better training was related to better glucose control, with less variability, independent of basal insulin regimen.

## 605

**Moderate exercise prevents morphological and functional adrenocortical alterations in rats with sucrose-induced insulin resistance**C. Martínez-Caleman<sup>1,2</sup>, J.M. Di Gruccio<sup>1,2</sup>, D. Jaume<sup>1,2</sup>, R. Sanchez<sup>1,2</sup>, M.E. Mercau<sup>1,2</sup>, F. Astort<sup>1,2</sup>, P. Arias<sup>3,4</sup>, C.B. Cymering<sup>1,2</sup>;<sup>1</sup>Human Biochemistry, University of Buenos Aires, <sup>2</sup>CEFyBO, Buenos Aires, <sup>3</sup>Physiology, University of Rosario, <sup>4</sup>Universidad Nacional del Litoral, Santa Fe, Argentina.

**Background and aims:** Previous results from our group demonstrate the impact of sucrose-induced insulin resistance on rat adrenocortical function and morphology. Physical activity reduces insulin resistance both in patients and in animal models with this metabolic derangement. Thus, we studied the effects of moderate physical exercise (PE) on the adrenocortical alterations already detected in rats with insulin resistance induced by sucrose-rich diets (SRD).

**Materials and methods:** Adult male Wistar rats received 30% sucrose in the drinking water or their usual diet for a period of 9 weeks. Sucrose-treated and control animals underwent a protocol of moderate PE on a treadmill (at  $0.8$  km/h up to  $6$  min,  $5$  days per week, groups SRD-E and C-E respectively). After 9 weeks, we measured insulin sensitivity (insulin tolerance test or ITT with  $0.75$  IU/kg insulin i.p.), adrenal function (basal and ACTH-stimulated serum corticosterone levels) and plasma ACTH levels. In adrenocortical tissue we determined triacylglyceride (TAG) and total cholesterol concentrations, the expression of proteins involved in steroidogenesis (StAR and CYP11A1) and its regulation (MC2R ACTH receptor), and inflammatory markers (TNF  $\alpha$ , F4/80, COX-2). We also performed a histochemical evaluation of the adrenal cortex. Similar analysis were performed also in sedentary animals receiving a SRD (SRD-S) or their usual diet (C-S). Values are expressed as mean  $\pm$  SEM. Differences between groups were analyzed by unpaired  $t$  test or by one-way ANOVA (Tukey's test).

**Results:** SRD-E animals exhibited lower body weight and glucose and insulin levels as compared to those measured in the corresponding SRD-S group. Results obtained by means of the ITT showed a significant amelioration of the  $k$  value (SRD-E  $1.88 \pm 0.43$  vs. SRD-S  $1.68 \pm 0.4$ ,  $\text{mg}^* \text{ml}/\text{min}$ ,  $p<0.005$ ). Insulin resistant animals submitted to PE showed significantly lower levels of adrenal TAG (SRD-E  $2.11 \pm 0.17$  vs. SRD-S  $2.89 \pm 0.19$   $\mu\text{g}^* \text{mg}$  tissue,  $p<0.01$ ). In agreement, the densitometric analysis of Sudan III staining of adrenocortical sections showed a significant decrease in lipid infiltration in SRD-E animals. PE also resulted in a significant decrease in the expression levels of CYP11A1, StAR, COX-2, F4/80 and TNF  $\alpha$ , and in elevated MC2R mRNA levels, as compared to the results obtained in the SRD-S group. Finally, PE blocked the increase in both basal ACTH (SRD-E  $48.7 \pm 5.56$  vs. SRD  $80.7 \pm 7.57$   $\text{pg}/\text{ml}$   $p<0.05$ ) and corticosterone (SRD-E  $7.8 \pm 0.11$  vs. SRD  $30.0 \pm 0.10$   $\text{ng}/\text{ml}$   $p<0.005$ ) levels present in SRD-S rats, and restored the subnormal adrenal

response to acute ACTH stimulation ( $\text{SRD-E } 4890 \pm 180$  vs.  $\text{SRD } 3840 \pm 131$  AUC arbitrary units  $p < 0.005$ ).

**Conclusion:** The implementation of a moderate PE protocol in SRD-treated animals normalized insulin sensitivity and prevented the onset of morphological and biochemical alterations in the adrenal cortex. This protocol also improved adrenal function and restored the response to acute ACTH stimulation. Taking these results, as well as previous data obtained using an insulin-sensitizing drug, in consideration, a causal relationship between insulin resistance, increased adrenocortical lipid deposition and deranged secretory function could be hypothesized.

## PS 040 Aspects of carbohydrate metabolism

### 606

#### Altered glycolytic and gluconeogenic fluxes within the liver underlie the diurnal variation in glucose production in type 2 diabetes

J. Radziuk, S. Pye;

Medicine, The Ottawa Hospital, Canada.

**Background and aims:** In type 2 diabetes, endogenous glucose production (EGP) and gluconeogenesis display diurnal rhythms which drive the fasting hyperglycemia and are absent in weight-matched, healthy controls. The present study was designed to evaluate the intrahepatic metabolic dynamics underlying the altered pattern of glucose production in type 2 diabetes.

**Materials and methods:** Subjects with type 2 diabetes ( $n=9$ ) and age / BMI-matched normal controls ( $n=7$ ) who were fasting after breakfast (8:00h) underwent a further 24h fasting study starting at 14:00h. [ $\text{U-}^{13}\text{C}$ ]glucose and [ $3\text{-}^{14}\text{C}$ ]lactate were infused concomitantly. Acetaminophen was administered at 16:00h on the day the study was initiated and at 7:00h the following day. EGP and an index of gluconeogenesis were determined from the plasma tracer concentrations.  $\text{C}^{14}$  label in  $\text{C}_2\text{-C}_5$  of both plasma and glucuronide-derived glucose provided a measure of the degree of label randomization in circulating glucose and hepatic glucose-6-phosphate. [ $\text{U-}^{13}\text{C}$ ]glucose and  $\text{C}^{14}$  glucose specific activity were also determined in glucuronide glucose.

**Results:** Mirrored by the index of gluconeogenesis, EGP rose slowly overnight from  $8.4 \pm 0.6$  to  $11.2 \pm 0.4 \mu\text{mol kg}^{-1}\text{min}^{-1}$  ( $p < 0.05$ ) by 7:00h in diabetes before falling back to rates matching those in controls ( $8.2 \pm 0.2 \mu\text{mol kg}^{-1}\text{min}^{-1}$ ). The rising EGP increased plasma glucose concentrations to a morning peak of  $8.5 \pm 0.7 \text{ mmol/l}$  with a subsequent fall to  $6.0 \pm 0.3 \text{ mmol/l}$ . Control subjects remained near  $5.0 \pm 0.2 \text{ mmol/l}$ . After equilibration,  $\text{C}_2\text{-C}_5$  label rose from  $41 \pm 2$  in control to  $52 \pm 1\%$  ( $p < 0.05$ ) of total plasma glucose  $\text{C}^{14}$  label in diabetic subjects. Glucuronide  $\text{C}_2\text{-C}_5$  label however was the same at  $42 \pm 2$  and  $44 \pm 5\%$ . [ $\text{U-}^{13}\text{C}$ ] glucuronide glucose enrichment was  $14 \pm 2\%$  of plasma glucose in controls and  $29 \pm 3\%$  in diabetes ( $p < 0.05$ ), while  $\text{C}^{14}$ glucuronide specific activity (normalized to infusion rate of [ $3\text{-}^{14}\text{C}$ ]lactate) was  $1859 \pm 225$  and  $1006 \pm 82 \text{ dpm/mg}$  in control and diabetic subjects ( $p < 0.05$ ).

**Conclusion:** Taken together these data suggest, in type 2 diabetes, an increased randomization in circulating glucose of  $\text{C}^{14}$ label from the 3<sup>rd</sup> position of lactate. This is accompanied by a decrease of glucuronide  $\text{C}^{14}$  label overall in diabetes, in the face of cyclic increases in gluconeogenic flux to the circulation. The best explanation is increased rates of both glycolysis and gluconeogenesis within the liver in type 2 diabetes, possibly within different metabolic zones. An increased hepatic glucose uptake, tracked by the [ $\text{U-}^{13}\text{C}$ ] glucose tracer, appears to be entrained with the increased gluconeogenic flux. These altered fluxes underlie the diurnal variation in glucose production in diabetes.

#### Estimated glucose disposal rate is associated with macro- and microvascular complications in adult type 1 diabetes patients

A. Florentiu, O. Savu, R. Barbu, D. Reurean-Pintilei, R. Lichiardopol, R. Rugina, E. Culita, M. Vintila;

<sup>1</sup>N.C. Paulescu Institute, Bucharest, Romania.

**Background and aims:** Insulin resistance in type 1 diabetes (T1DM) patients has been consistently linked to the prevalence of certain complications of diabetes and especially to cardiovascular disease (CVD). While the standard test for quantification of insulin resistance is the euglycemic hyperinsulinemic clamp, a simple formula for estimation of glucose disposal rate from clinical and metabolic parameters has been validated. In this study we aimed to assess the relation between estimated glucose disposal rate (eGDR) and prevalence of CVD, microvascular complications, and nonalcoholic fatty liver disease (NAFLD) in a group of adult T1DM patients.

**Materials and methods:** We assessed adult patients with T1DM, recording personal history of arterial hypertension (HTN), CVD, microvascular diabetic complications, NAFLD status, waist-to-hip ratio (WHR) and biochemistry (HbA1c). Resting electrocardiogram and ankle-brachial index were used to screen for unknown CVD. Fundoscopic eye examination, urine analysis and feet skin sensibility tests were used to screen for unknown microvascular dia-

betic complications. Abdominal ultrasonography was performed to diagnose incident NAFLD. eGDR was calculated according to the formula validated by Williams et al:  $eGDR = 24.31 - 12.22 \times WHR - 3.29 \times HTN - 0.57 \times HbA1c$  [mg/kg/min]. The prevalences of CVD, NAFLD and diabetic complications were analyzed according to tertiles of eGDR distribution. Logistic regression analysis was employed to define the relation between CVD, microvascular complications and NAFLD prevalence, and eGDR and other variables. SPSS software was used for statistical analyses. A  $p$  value  $<0.05$  was considered significant.

**Results:** Data from 267 patients (123 male, 144 female), aged between 18 and 78 years and with a mean (SD) disease duration of 13 (10.2) years, was collected. Patients with eGDR in the first tertile had an over 7-fold higher prevalence of CVD, as compared to the upper tertile (52.2% vs. 6.8%,  $p < 0.001$ ). We found no case of CVD in patients with  $eGDR > 8.2$  mg/kg/min. In logistic regression eGDR and CVD were correlated (adjusted  $r^2 = 0.18$ ,  $p < 0.001$ ). When age was introduced in the model the relation did not lose its statistical significance. A multiple logistic regression model including age and eGDR was the best in predicting CVD (adjusted  $r^2 = 0.26$ ). The microvascular diabetic complications (74.4% vs. 47.7%,  $p < 0.001$ ) and NAFLD (33.3% vs. 13.6%,  $p = 0.001$ ) were more prevalent in the first tertile of eGDR distribution, as compared to the third tertile.

**Conclusion:** Our data suggest that insulin resistance is associated with a greater prevalence of CVD in type 1 diabetic patients, independently of age and disease duration. The only other variable associated with CVD prevalence was age. Insulin resistance was also associated with the microvascular complications burden and the prevalence of NAFLD. Estimation of GDR by a simple formula can be useful in clinical practice to stratify the risk of macro and microvascular complications in selected type 1 diabetes patients.

## 608

### The insulin-independent glucose-induction of the hepatic gluconeogenic enzyme glucose 6-phosphatase involves distinct metabolic pathways and transcription factors

Z.H. Al-Oanzi<sup>1,2</sup>, J.L. Petrie<sup>1</sup>, S. Tudhope<sup>1</sup>, C. Arden<sup>1</sup>, L. Agius<sup>1</sup>;

<sup>1</sup>Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK, <sup>2</sup>College of Applied Medical Sciences, Al-Jouf University, Skaka, Saudi Arabia.

**Background and aims:** Elevated hepatic gluconeogenesis is a contributing factor to fasting and postprandial hyperglycaemia in type 2 diabetes. Elevated expression of glucose 6-phosphatase (G6pc) the enzyme that catalyses the final reaction in hepatic glucose production is generally attributed to a defect in insulin repression. However G6pc is also induced by hyperglycaemia. The aim of this study was to determine the mechanisms by which glucose induces G6pc in liver.

**Materials and methods:** Rat hepatocytes in short term primary culture were used to study the induction of G6pc mRNA expression by high glucose (25mM versus 5mM). The role of specific transcription factors was tested by over-expression of wild-type or dominant negative variants and by chromatin immunoprecipitation assays. The metabolic events by which glucose causes transcriptional activation were studied using selective inhibitors of the hexosamine pathway or expression of enzyme variants.

**Results:** Expression of G6pc mRNA in hepatocytes was repressed by 10 nM insulin but it was induced by glucose (25mM vs 5mM) in both the absence and presence of insulin (G6pc mRNA; 5mM, 1.0; 25mM,  $12 \pm 2.3$ ,  $P < 0.01$ ; 5mM+insulin,  $0.3 \pm 0.1$ ; 25mM+insulin,  $1.2 \pm 0.3$ ,  $P < 0.01$ ). The glucose-induction of G6pc expression was attenuated but not abolished by expression of a dominant-negative (DN) variant of Mlx and this attenuation was reversed by expression of ChREBP but not MondoA (25mM,  $8.9 \pm 2.7$ ; +Mlx-DN,  $4.4 \pm 1.4$ ,  $P < 0.05$ ; +Mlx-DN+ChREBP,  $14 \pm 3.2$ ,  $P < 0.05$ ; +Mlx-DN+MondoA,  $3.2 \pm 1.4$  NS). A role for endogenous ChREBP but not MondoA was further shown by chromatin immunoprecipitation assays, confirming an exclusive role for ChREBP-Mlx in the attenuation by Mlx-DN. Candidate transcription factors for the Mlx-independent component of the glucose-induction include Foxo transcription factors as confirmed by overexpression studies and lack of repression by Mlx-DN (25mM,  $3.8 \pm 1.3$ ; +Foxo3A,  $9.4 \pm 2.7$ ; +Mlx-DN,  $2.2 \pm 0.2$ ; +Mlx-DN+Foxo3A,  $5.8 \pm 0.6$ ). Two metabolic signals were identified in the G6pc-induction by high glucose. (i) Fructose 2,6-bisP, as supported by repression of G6pc induction with a Kinase-Deficient variant of PFKFBP1 that abolished the glucose elevation of this regulator (25mM,  $14 \pm 5.2$  vs 25mM+KD,  $3.7 \pm 1.1$ ); (ii) Hexosamine pathway flux as supported by the attenuation with a GFAT (glutamine:fructose 6-P amidotransferase) inhibitor (25mM,  $3.9 \pm 1.5$  vs 25mM+I,  $0.9 \pm 0.5$   $P < 0.05$ ). The independence of the two signals was shown by lack of effect of the GFAT inhibitor on fructose

2,6-bisP (5mM,  $34 \pm 7.1$ ; 25mM,  $281 \pm 46$  25mM+I,  $293 \pm 54$ ) and by the lack of effect of fructose 2,6-bisP depletion on hexosamine pathway end-product (5mM,  $0.7 \pm 0.6$ ; 25mM,  $1.1 \pm 0.7$  25mM+KD,  $1.0 \pm 0.6$ ).

**Conclusion:** The insulin-independent glucose-induction of G6pc in hepatocytes is in part mediated by ChREBP-Mlx and in part by additional transcriptional regulators. At least two independent metabolic signalling events involving fructose 2,6-bisP and flux through the hexosamine pathway are involved in the glucose induction. This supports the hypothesis that glucose induction of G6pc and the consequent glucose intolerance is a crucial adaptive mechanism to protect the liver from substrate overload that results in fatty liver.

### Postprandial capillary density is blunted in men with type 2 diabetes mellitus or metabolic syndrome

R.E. Van Genugten, E.H. Serné, D.H. Van Raalte, M. Diamant;

Diabetes Center, Department of Internal Medicine, VU University Medical Center, Amsterdam, Netherlands.

**Background and aims:** Microvascular capillaries are known to contribute to overall glucose uptake and a decreased functional capacity is related to peripheral insulin resistance. Steady-state hyperinsulinaemia increases capillary density (i.e. capillary recruitment), as measured by euglycaemic-hyperinsulinaemic clamp technique. We investigated whether similar responses occur after ingestion of a mixed meal and hypothesised that postprandial microvascular function, compared to healthy controls, is impaired in metabolic syndrome (MetS) and type 2 diabetes (T2DM), and is associated with insulin sensitivity and postprandial hyperglycaemia.

**Materials and methods:** We recruited 12 healthy men, 13 with MetS (IDF-criteria) without T2DM and 12 with uncomplicated T2DM. Microvascular function was assessed by skin capillary video microscopy. Capillary density at baseline and during post-occlusive peak reactive hyperaemia (PRH) was assessed fasting (T0), and 60 (T60) and 120 minutes (T120) after ingestion of a standardised solid mixed-meal (total 900 kCal/50g fat/75g carbohydrates/37g protein). Oral glucose insulin sensitivity (OGIS) and postprandial hyperglycaemia (4h-AUC<sub>glucose</sub>) were calculated. Repeated-measures ANOVA and Pearson correlation were used for statistical analysis.

**Results:** Groups were matched for age (mean $\pm$ SD:  $56.6 \pm 5.7$  y) and, as expected, differed significantly with respect to BMI, fasting and postprandial glucose, HbA1c and OGIS (all  $P < 0.05$ ). In the fasting state, baseline capillary density was similar among groups (controls  $40.1 \pm 6.6$ ; MetS  $35.5 \pm 7.9$ ; T2DM  $39.4 \pm 4.7$  n/mm<sup>2</sup>  $P = ns$ ), but PRH was lowest in T2DM, with intermediate values for MetS ( $P = 0.048$ ). Postprandial capillary recruitment was blunted in MetS and T2DM (PRH T60 vs. T0  $P < 0.05$  for HC only; T120 vs. T0  $P < 0.05$  for all groups). In all groups, postprandial AUC for PRH correlated with OGIS ( $r = 0.492$   $P < 0.05$ ) and with 4h-AUC<sub>glucose</sub> ( $r = 0.350$   $P < 0.05$ ).

**Conclusion:** Both MetS and T2DM individuals are characterised by decreased capillary density during PRH in the fasting state and impaired meal-related capillary recruitment. In pooled analysis, postprandial capillary recruitment during PRH was associated with both insulin sensitivity and postprandial hyperglycaemia. These findings suggest that in T2DM, microvascular dysfunction might contribute to postprandial hyperglycaemia while in individuals with MetS, who are at high risk to develop T2DM, it may contribute to glucose intolerance.

### In vivo insulin clearance regulation: a role for nitric oxide

F.O. Martins<sup>1,2</sup>, J.G. Jones<sup>1,3</sup>, R. Ribeiro<sup>2,3</sup>, A. Mari<sup>4</sup>, A. Natali<sup>2,5</sup>, M.P. Macedo<sup>2,3</sup>;

<sup>1</sup>Centre for Neurosciences and Cell Biology, University of Coimbra, Portugal, <sup>2</sup>Centro de Estudos de Doenças Crónicas, New University of Lisbon, Portugal, <sup>3</sup>Portuguese Diabetes Association (APDP-ERC), Lisbon, Portugal, <sup>4</sup>Institute of Biomedical Engineering, CNR, Padova, Italy, <sup>5</sup>Metabolism Unit, Department of Internal Medicine, University of Pisa, Italy.

**Background and aims:** Impairment on insulin clearance (IC) is an early event in the disturbance of glucose metabolism, as it is observed in first-degree relatives of type 2 diabetics and in obese insulin resistant subjects. IC is a major component of ineffective control of peripheral insulin levels found in

those conditions. The mechanisms that regulate IC have been overlooked but have a major influence on the amount of insulin that reaches the periphery. Even though it is well established that nitric oxide (NO) regulates peripheral insulin sensitivity and alters, *in vitro*, the activity of the insulin degrading enzyme (IDE), its role on IC and  $\beta$ -cell sensitivity modulation is not clear. Herein, we tested the hypothesis that, *in vivo*, NO decreases  $\beta$ -cell sensitivity and hepatic IC by inhibiting IDE activity.

**Material and methods:** In this study, 12 weeks male Wistar rats were divided in two groups: nitric oxide synthase (NOS) acutely inhibited [L-nitroarginine methyl ester (L-NAME); 35 ug/kg/min; i.v.] and NOS chronically inhibited (L-NAME 10 mg/kg; daily; 4 weeks; s.c.) animals. Each animal was submitted to an intra-enteric glucose tolerance test (IEGTT) and plasma samples (0, 15, 30, 60, 90 and 120 min after the glucose bolus) were collected for analysis of insulin and c-peptide levels. Hepatic IDE activity and expression were measured in liver tissue. Total IC was quantified from the ratio of plasma c-peptide and insulin levels as well as through the slope of the best linear fit between c-peptide and plasma insulin levels.  $\beta$ -cell sensitivity was obtained from the average slope of the lines in the representation of c-peptide plotted against the corresponding glucose levels.

**Results:** Acute but not chronic L-NAME treatment decreased plasma glucose excursions during the IEGTT (AUC: Control:  $21686 \pm 809,0$ ; Acute L-NAME:  $18356 \pm 511,9$ ,  $p < 0,05$ ; Chronic L-NAME:  $23233 \pm 499,6$ , n.s.). Both L-NAME treatments promoted an increase in total IC (AUC: Control:  $78237 \pm 3283$ ; Acute L-NAME:  $128278 \pm 7954$ ,  $p < 0,001$ ; Chronic L-NAME:  $103445 \pm 4344$ ,  $p < 0,05$ ) which was associated with an increase in hepatic IDE activity (RFUs/mg protein: Control:  $7,8 \pm 0,8$ ; Acute L-NAME:  $12,4 \pm 1,7$ ,  $p < 0,05$ ; Chronic L-NAME:  $10,4 \pm 0,4$ ,  $p < 0,05$ ). Hepatic IDE expression did not change with L-NAME treatment. Moreover, both acute and chronic L-NAME treatments also attenuated the decrease in IC occurring in the transition from fast to fed after the intraenteric bolus of glucose (% decrease: Control:  $66,9 \pm 4,5$ ; Acute L-NAME:  $49,2 \pm 4,4$ ,  $p < 0,05$ ; Chronic L-NAME:  $40,0 \pm 4,1$ ,  $p < 0,01$ ). Finally,  $\beta$ -cell sensitivity significantly increased with both acute and chronic L-NAME treatment (slope: Control:  $17,0 \pm 2,602$ ; Acute L-NAME:  $29,2 \pm 2,3$ ,  $p < 0,05$ ; Chronic L-NAME:  $10,24 \pm 3,0$ ,  $p < 0,05$ ).

**Conclusion:** In conclusion, our results support the hypothesis that NO is a physiological regulator of IC, by inhibiting hepatic IDE activity, and resulting in decreased  $\beta$ -cell sensitivity. These results support the hypothesis that in insulin resistance states, where inducible NOS is increased, IC is impaired and hyperinsulinemia come into sight.

**A 5-day high fat high calorie diet impairs insulin sensitivity in healthy, young, lean male Dutch Surinamese South Asians but not in Dutch Caucasians**

L.E.H. Bakker<sup>1</sup>, B. Guigas<sup>2</sup>, T.C.M. Streefland<sup>3</sup>, H. Pijl<sup>3</sup>, A.E. Meinders<sup>1</sup>, I.M. Jazet<sup>1</sup>;

<sup>1</sup>Endocrinology/General Internal Medicine, <sup>2</sup>Molecular Cell Biology,

<sup>3</sup>Endocrinology, LUMC, Leiden, Netherlands.

**Background and aims:** People of South Asian descent, such as the Surinamese South Asian population in The Netherlands, develop type 2 diabetes and cardiovascular diseases at a much younger age and lower BMI compared to Caucasians. Moreover, the incidence and seriousness of these diseases is higher in South Asians than in Caucasians. The underlying cause remains unknown but might be related to differences in fatty acid handling leading to impaired skeletal muscle insulin signalling leading to insulin resistance. The aim of this study was to investigate whether whole body insulin sensitivity and substrate oxidation, and skeletal muscle insulin signalling are different between healthy young lean male South Asians and Caucasians at baseline, and whether the response to a 5-day high fat high calorie (HFHC) diet differs between both ethnicities.

**Materials and methods:** 12 male South Asians and 12 male Caucasians (age  $22.2 \pm 0.65$  vs  $22.1 \pm 0.60$  years ( $p = 0.93$ ), BMI  $20.9 \pm 0.58$  vs  $22.3 \pm 0.59$  kg/m<sup>2</sup> ( $p = 0.11$ )) were studied before and after a 5-day-HFHC-diet, consisting of their regular diet, supplemented with 375 ml cream per day (=1275 kcal/day, 94% fat). Endogenous glucose production (EGP, [6,6-<sup>2</sup>H<sub>2</sub>]-glucose), whole body glucose disposal rate (GDR) and substrate oxidation rates (indirect calorimetry) were measured before and after the diet in basal condition and during a hyperinsulinemic euglycemic clamp (insulin infusion rate step 1: 10 mU/m<sup>2</sup>/min, step 2: 40 mU/m<sup>2</sup>/min). In addition, skeletal muscle biopsies were obtained from the vastus lateralis muscle, in basal and hyperinsulinemic euglycemic conditions for determination of insulin signalling.

**Results:** In step 1 no differences were found in our major endpoints. In step 2 EGP decreased from  $11.6 \pm 1.0$  to  $10.2 \pm 0.5$   $\mu\text{mol/kg}_{\text{LBM}}/\text{min}$  ( $p = 0.01$ ) in the South Asian group, but this was at higher serum insulin levels due to a lower metabolic clearance rate of insulin as compared to Caucasians. Despite the higher serum insulin levels, GDR in step 2 decreased from  $53.1 \pm 2.2$  to  $41.8 \pm 2.0$   $\mu\text{mol/kg}_{\text{LBM}}/\text{min}$  ( $p < 0.001$ ) after a 5-day-HFHC-diet. This appeared to be due to a decrease in non-oxidative glucose disposal rate (NOGD) in step 2 ( $35.8 \pm 3.1$  to  $20.6 \pm 2.9$   $\mu\text{mol/kg}_{\text{LBM}}/\text{min}$  ( $p < 0.001$ )). EGP and GDR in the Caucasian group did not change after the diet. No differences were found in oxidative glucose disappearance and lipid oxidation rates. In addition, no major alterations in skeletal muscle insulin signalling pathways were detected, both at baseline and during insulin stimulation.

**Conclusion:** A 5-day-HFHC-diet already impaired insulin stimulated non-oxidative glucose disposal in apparently healthy, young, lean male South Asians, whereas no such effect was observed in matched Caucasians. Since no differences were found in insulin signalling, the decrease in insulin sensitivity in South Asians is possibly due to mitochondrial dysfunction.

**Pancreatic exocrine function and morphology in patients with type 2 diabetes**

I. Miñambres, A. Farré, C. Pérez, M. Cortés, J. Monill, C. Martínez, A. Pérez; Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

**Background and aims:** Diabetes mellitus has been associated with chronic pancreatitis. However, in type 2 diabetes, information regarding morphological and functional changes of the exocrine pancreas remains scarce. Our aim was to study functional and morphological characteristics of the exocrine pancreas in patients with type 2 diabetes.

**Materials and methods:** We included 23 subjects (65% men) with type 2 diabetes. Mean age was  $64 \pm 8.6$  years, mean diabetes duration was  $13 \pm 11$  years, and 65% of the subjects were treated with insulin. Morphological and functional characteristics of the exocrine pancreas were evaluated by means of secretin-magnetic resonance cholangiography and measurement of fecal elastase. Pancreas morphology was classified according to Cambridge classification and pancreatic insufficiency was determined according to the volume of fluid secreted into the duodenum in response to secretin. Fecal elastase values  $> 200$  ug/g were considered normal. Statistical analysis included Chi-squared test and Mann-Whitney test.

**Results:** Fourteen subjects (61%) presented morphological changes suggestive of chronic pancreatitis (6 severe, 5 moderate, 3 mild). Six patients (26%) presented mild pancreatic insufficiency according to the degree of duodenal repletion after stimulation with secretin. Median concentrations of fecal elastase were 451 ug/g (62-500) and only two patients had levels  $< 200$  ug/g. Pharmacological treatment duration was higher in subjects with morphological signs of chronic pancreatitis than in subjects without (14 (2-31) years vs. 6 (0,25-23) years;  $p = 0,043$ ). No associations were found between morphological signs of chronic pancreatitis and sex, age, diabetes duration, type of treatment for diabetes, the presence of pancreatic insufficiency or fecal elastase levels.

**Conclusion:** Most patients with type 2 diabetes present morphological changes of the exocrine pancreas suggestive of chronic pancreatitis. Functional repercussion is less frequent.

## PS 041 Hypoglycaemia: relation to therapy

613

### A 5 year study of severe treatment-induced hypoglycaemia in diabetes: patient characteristics and first year mortality

A.C. Huskinson<sup>1</sup>, M.J. Bottomley<sup>1</sup>, L. Clapham<sup>2</sup>, C. James<sup>2</sup>, S.H. Alzahrani<sup>1</sup>, R. King<sup>1</sup>, R.A. Ajjan<sup>1</sup>;

<sup>1</sup>Division of Diabetes and Cardiovascular Research, Multidisciplinary Cardiovascular Research Centre, Leeds Institution of Genetics, Health and Therapeutics, University of Leeds, UK, <sup>2</sup>Leeds Teaching Hospitals Trust, Leeds, UK.

**Background and aims:** Hypoglycaemia is a common complication of diabetes treatment and can be life-threatening. The aim of this work was to establish the characteristics of individuals with diabetes in the community sustaining severe hypoglycaemia requiring emergency services intervention. **Materials and methods:** This study attempted to record ambulance call outs for severe hypoglycaemia over a period of 5.5 years amongst a population of approximately 28,000 subjects with diabetes.

**Results:** A total of 1312 episodes were recorded in 858 subjects, with 55% occurring in individuals with type 1 diabetes (T1DM), 39% in type 2 diabetes (T2DM) and a minority unclassified. Two third of T1DM subjects were males, whereas gender distribution was equal amongst T2DM individuals. Mean age of T1DM subjects was 48.7 years (range: 8–95), whereas T2DM subjects were older at 72.8 years (range: 32–97). Of the T2DM subjects, 27% were not on insulin treatment with the majority receiving a sulphonylurea (90%). Mean capillary blood glucose ( $\pm$ SEM) at arrival of emergency services was lower in T1DM compared with T2DM subjects ( $1.71 \pm 0.32$  mmol/L and  $1.96 \pm 0.38$  mmol/L, respectively;  $p < 0.001$ ). In T2DM individuals, the severity of hypoglycaemia in insulin users and non-insulin users was similar at  $1.93 \pm 0.50$  mmol/L and  $1.98 \pm 0.55$  mmol/L, respectively ( $p = 0.51$ ). HbA<sub>1c</sub> was higher in T1DM than T2DM subjects ( $66 \pm 1$  mmol/mol and  $60 \pm 1$  mmol/mol, respectively;  $p < 0.001$ ), and insulin users in T2DM had significantly higher HbA<sub>1c</sub> compared with those not on this therapy. Around one third of patients self-reported hypoglycemic unawareness. Basal-bolus regime was more commonly used in T1DM subjects compared with T2DM (61.5% and 13.7%, respectively;  $p < 0.001$ ). In contrast, a mixed insulin regime was more frequently used in T2DM compared with T1DM individuals (68.6% and 24.4%, respectively;  $p < 0.001$ ). Mortality within one year of the severe hypoglycemic event was 17.1% in the whole population, which is comparable to the one year mortality of 15.6% following myocardial infarction in diabetes subjects in our area.

**Conclusion:** This observational study demonstrates that severe hypoglycaemia is a common complication in both T1DM and T2DM, and frequently occurs in non-insulin treated individuals, the majority of which are on sulphonylurea therapy. We show high mortality in the first year following severe hypoglycaemia, although it is unclear at present whether low blood glucose directly contributes to death in these individuals. Future work is warranted to establish whether specialist intervention following severe hypoglycaemia reduces further events or mortality in this high risk population.

614

### Substantial reduction in the frequency of severe hypoglycaemic events in children and adolescents with type 1 diabetes in Denmark in the period 2008–2011

S. Fredheim<sup>1</sup>, A. Johansen<sup>2</sup>, L.B. Nielsen<sup>1</sup>, M.-L.M. Andersen<sup>1</sup>, J. Johannesen<sup>1</sup>, H.B. Mortensen<sup>1</sup>, J. Svensson<sup>1</sup>;

<sup>1</sup>Pediatric Ward, Herlev University Hospital, <sup>2</sup>Pediatric Ward, Rigshospitalet, Blegdamsvej 9, 2100 Copenhagen, Denmark.

**Background and aim:** Recent advances in diabetes treatment regimens call for an evaluation of current practice. This national study aimed at describing the metabolic outcome and the frequency of acute adverse outcome in children and adolescents with Type 1 Diabetes (T1D) according to treatment modalities within the recent 4 years in Denmark.

**Materials and methods:** A national register-based study including children and adolescents < 17 years from Denmark diagnosed with T1D followed from 2008 till 2011 both year included. Clinical data was prospectively recorded, including events of severe hypoglycaemia (SH) and annual glycated

haemoglobin A1c (HbA1c). SH was defined as unconsciousness and/or seizures and a blood glucose level of < 3.5 mmol/L. A negative binominal model was used to evaluate the current treatment modality to the frequency of SH over the following 4 years.

**Results:** 1271 children (girls 49.2 %, boys 50.8 %) were included in the study. Data completeness for individual and annual HbA1c recordings in the period has increased from 2008 (80 %) till 2012 (86 %), as did recordings of SH in 2008 (81 %) till 2012 (87 %). We observe a decreasing frequency of SH with -0.38 % (SEM 0.05,  $p < 0.001$ ) pr. year in our population. Stratified according to the time period, we observe a decreasing frequency of SH: 9.7 % (2008), 8.4 % (2009), 5.5 % (2010) and 4.6 % (2011). The overall mean HbA1c over the respective 4 years do not significantly improve (8.31 % 2008, 8.26 % 2009, 8.32 % 2010, 8.35 % 2011). There is a significant increasing frequency of SH associated to increasing HbA1c levels ( $p = 0.03$ ), however when adjusting for treatment modality this finding is no longer present. In the same period, a decreasing number of patients are on multiple daily insulin injections: 78.1 % (2008) to 51.6 % (2011), and an increasing number of patients are treated with continuous subcutaneous insulin injections (CSII): 21.9 % (2008) to 48.4% (2011). We observe a significant decreasing frequency of SH for patients on CSII compared to MDI, -0.032 (SEM=0.13,  $p = 0.014$ ).

**Conclusion:** Although long-term HbA1c-levels are unaltered, we observe an overall substantial decrease in severe hypoglycaemic events in Denmark. Despite an increasing number of patients on CSII treatment, these patients experience fewer SH events, also as HbA1c improves.

615

### Prospectively planned meta-analysis comparing hypoglycaemia rates of insulin degludec with those of insulin glargine in all patients and an elderly ( $\geq 65$ year) subgroup

S.C.L. Gough<sup>1</sup>, R. Ratner<sup>2</sup>, C. Mathieu<sup>3</sup>, S. Del Prato<sup>4</sup>, B. Bode<sup>5</sup>, H. Mersebach<sup>6</sup>, L. Endahl<sup>6</sup>, B. Zinman<sup>7</sup>;

<sup>1</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, UK, <sup>2</sup>MedStar Health Research Institute, Hyattsville, USA, <sup>3</sup>Katholieke Universitet Leuven, Belgium, <sup>4</sup>University of Pisa, Italy, <sup>5</sup>Atlanta Diabetes Associates, Atlanta, USA, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, Canada.

**Background and aims:** Insulin degludec (IDeg), a new basal insulin that forms soluble multi-hexamers after sc injection, has an ultra-long and stable glucose-lowering effect with low day-to-day variability. This pre-specified analysis compared the hypoglycaemia rate with IDeg vs insulin glargine (IGlar) in patients with type 1 and type 2 diabetes (T1D and T2D).

**Materials and methods:** Hypoglycaemia was defined as self-reported confirmed hypoglycaemia (plasma glucose < 3.1 mmol/l or severe hypoglycaemia requiring assistance) and nocturnal confirmed hypoglycaemia (00:01–05:59, inclusive). Rates were analysed with a negative binomial regression model on patient-level data. All open-label, randomised, treat-to-target phase 3a trials of 26 or 52 weeks in which once-daily IDeg ( $n = 2899$ ) was compared to IGlar ( $n = 1431$ ) in T1D (2 trials) and T2D (5 trials) were included. We also present a pre-planned sub-analysis in subjects aged  $\geq 65$  years (IDeg  $n = 632$ ; IGlar  $n = 283$ ).

**Results:** IDeg was associated with statistically significant lower rates of overall and nocturnal hypoglycaemia vs IGlar in T2D, and of nocturnal hypoglycaemia in T1D (Table). A significant advantage of IDeg was also evident for the pooled population (T1D+T2D). Analyses of the maintenance period (stable glycaemia and insulin dose [obtained from 16 weeks onward]), demonstrated a more pronounced advantage of IDeg. Additional analysis revealed significantly less severe hypoglycaemia with IDeg vs IGlar in insulin-naïve T2D (rate ratio [RR] 0.14 [95% CI: 0.03; 0.70]). Across trials, 21.1% of all subjects (6.4% T1D, 25.3% T2D) were  $\geq 65$  years. Consistent with confirmatory analyses in the overall population, elderly subjects had fewer confirmed hypoglycaemic episodes with IDeg vs IGlar. Confirmed hypoglycaemia was numerically lower in IDeg-treated elderly subjects (RR IDeg/IGlar: 0.82 [95% CI: 0.66; 1.00]). Nocturnal hypoglycaemia rates were significantly lower with IDeg (RR 0.65 [95% CI: 0.46; 0.93]).

**Conclusion:** Treatment with IDeg provides important clinical advantages with significantly lower rates of overall and nocturnal hypoglycaemia vs IGlar at similar HbA<sub>1c</sub> levels. Elderly subjects treated with IDeg experience a numerically lower rate of confirmed hypoglycaemia and a significantly (35%) lower nocturnal hypoglycaemia rate with IDeg vs IGlar, confirming that of individual trial data from the IDeg clinical program. Lower rates of hypoglycaemia associated with IDeg may be of particular benefit in the elderly population on insulin.

## Meta-analysis of confirmed hypoglycaemia for IDeg vs IGLar in all subjects

	Hypoglycaemia rate ratio (IDeg/IGlar)		Nocturnal hypoglycaemia rate ratio (IDeg/IGlar)	
	Total period	Maintenance period <sup>a</sup>	Total period	Maintenance period <sup>a</sup>
T2D	0.83 [0.74; 0.94]*	0.75 [0.66; 0.87]*	0.68 [0.57; 0.82]*	0.62 [0.49; 0.78]*

### The risk of first severe hypoglycaemia depends on the type of basal insulin but does not differ between patients with type 1 and type 2 diabetes: The EpiHypo Study

P. Korhonen<sup>1</sup>, J. Haukka<sup>1</sup>, F. Hoti<sup>1</sup>, P. Erästä<sup>1</sup>, S. Mäkimattila<sup>2</sup>, T. Saukkonen<sup>2</sup>; <sup>1</sup>EPID Research, Espoo, Finland, <sup>2</sup>Novo Nordisk, Espoo, Finland.

**Background and aims:** While incidence of severe hypoglycaemia (SH) is well documented in type 1 diabetes (T1D), there is limited information on frequency of SH in type 2 diabetes patients (T2D) receiving insulin therapy. The aim of this retrospective follow-up study was to investigate the incidence and risk factors of hospitalisation and secondary health care visits due to SH in patients with T1D or T2D using NPH, glargine (IGla), or detemir (IDet) insulin.

**Materials and methods:** Data was obtained by linking Finnish nationwide health care databases. Study population included all diabetes patients (n=137 994) entitled to special reimbursement for diabetes medication and who had purchased insulin during 2000–2009. The present analysis comprised those patients (n=75 682) who had not used insulin before year 2000. Stratified incidence rates with 95% CIs were calculated. Hazard ratios (HR) were estimated by Cox's proportional hazards model, adjusted for age, gender, prior and current use of other insulins and sulfonylureas, switch between insulins, history of hypoglycaemia, years from diagnosis, calendar year of the start of follow-up and hospital district.

**Results:** We identified altogether 842 and 2732 first incident SHs in patients with T1D and T2D, respectively. Incidence of first SH was 1.74 (1.64–1.86) in T1D and 1.91 (1.85–1.98) in T2D per 100 patient years (ptys). Type of diabetes was not significantly associated with risk of first SH (HR 1.11, CI 0.99–1.25, *p*=0.079 for T2D vs T1D), however the risk of recurrence of SH was significantly higher in T2D (1.40, CI 1.24–1.58, *p*<0.001) compared to T1D. The results for the incidence and risk of first SH during the use of NPH, IGla or IDet are shown in Table.

	Ptyrs	Events	Incidence (95% CI) / 100 ptyrs	HR (95% CI) vs. NPH	p value	HR (95% CI) vs. glargine	p value
T1D							
NPH	19563	454	2.32 (2.12 - 2.54)	1			
IGla	18850	272	1.44 (1.28 - 1.63)	0.73 (0.60 - 0.89)	0.002	1	
IDet	9520	116	1.22 (1.02 - 1.46)	0.67 (0.52 - 0.88)	0.003	0.92 (0.74 - 1.16)	0.490
T2D							
NPH	96164	1937	2.01 (1.93 - 2.11)	1			
IGla	33958	660	1.94 (1.80 - 2.10)	0.96 (0.85 - 1.08)	0.460	1	
IDet	10120	135	1.33 (1.13 - 1.58)	0.74 (0.60 - 0.90)	0.003	0.77 (0.64 - 0.93)	0.006

**Conclusion:** Based on the EpiHypo register study, risk of hospitalisation due to SH is similar or even increased in insulin-treated T2D compared to T1D. In T1D, both long-acting insulin analogues were associated with lower risk of SH compared to NPH. In T2D, risk of hospitalisation due to SH was significantly lower during use of IDet compared to both IGla and NPH.

### Lower rates of overall and nocturnal hypoglycaemia with insulin degludec vs insulin glargine during treatment intensification in type 2 diabetes patients: a meta-analysis

A.J. Garber<sup>1</sup>, S. Colagiuri<sup>2</sup>, H.W. Rodbard<sup>3</sup>, S. Rasmussen<sup>4</sup>, N. Lassota<sup>4</sup>, S.C.L. Gough<sup>5</sup>;

<sup>1</sup>Department of Medicine, Baylor College of Medicine, Houston, USA,

<sup>2</sup>University of Sydney, Australia, <sup>3</sup>Endocrine and Metabolic Consultants,

Rockville, USA, <sup>4</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>5</sup>University of

Oxford, UK.

**Background and aims:** Current basal insulin treatments increase the risk of hypoglycaemia when HbA<sub>1c</sub> levels approach normoglycaemia. Insulin degludec (IDeg) is a new basal insulin that forms soluble multi-hexamers upon subcutaneous injection, resulting in an ultra-long action profile with a low day-to-day variability.

**Materials and methods:** We analysed whether these characteristics of IDeg would improve glycaemic control and result in lower rates of hypoglycaemia compared to insulin glargine (IGlar) in patients with type 2 diabetes (T2D) in moderately good control at baseline (HbA<sub>1c</sub> of 7.5–8.5%). Changes in HbA<sub>1c</sub> and fasting plasma glucose (FPG) were analysed with linear models, and rates of hypoglycaemia with a negative binomial regression model. Hypoglycaemia was defined as self-reported confirmed hypoglycaemia (PG <3.1 mmol/L) or severe episodes if requiring assistance; nocturnal confirmed hypoglycaemia was defined as onset between 00:01 and 05:59 inclusive. Analysis included patient-level data from all five open-label randomised treat-to-target phase 3a trials in T2D (26 or 52 weeks) in which IDeg (n=930) or IGlar (n=446) were given once daily.

**Results:** HbA<sub>1c</sub> decreased from 8.0% at baseline in both groups to 7.0 versus 6.9% at end of trial for IDeg versus IGlar, respectively (treatment difference: 0.08%-points [95% CI: -0.01; 0.18]; *p*=0.08). Observed FPG decreased from 9.0 to 6.1 mmol/L for IDeg and from 8.9 to 6.3 mmol/L for IGlar, achieving a statistically significant estimated treatment difference of -0.36 mmol/L [95% CI: -0.60; -0.11]; *p*<0.01. The rate ratio (IDeg:IGlar) of confirmed hypoglycaemia (0.80 [95% CI: 0.67; 0.96]; *p*=0.02) and nocturnal hypoglycaemia (0.69 [95% CI: 0.51; 0.92]; *p*=0.01) were both statistically significantly lower for IDeg versus IGlar.

**Conclusion:** Patients with T2D with baseline HbA<sub>1c</sub> of 7.5–8.5% treated with IDeg showed comparable improvement in HbA<sub>1c</sub>, significantly greater reduction in FPG, and significant reduction (20%, 31%) in rates of overall and nocturnal hypoglycaemia, respectively, compared to IGlar.

### Hypoglycaemia risk in type 2 diabetes: a multivariate analysis comparing exenatide once weekly with insulin glargine experience in a large clinical trial dataset

S.K. Paul<sup>1</sup>, K. Klein<sup>1</sup>, D. Maggs<sup>2</sup>, J.H. Best<sup>2</sup>;

<sup>1</sup>University of Queensland, Brisbane, Australia, <sup>2</sup>Medical Research and Development, Amylin Pharmaceuticals, San Diego, USA.

**Background and aims:** The time-varying effects of risk factors on hypoglycaemia in patients with type 2 diabetes are not known. This post-hoc analysis explored the possible association of anthropometric and clinical risk factors with hypoglycaemia risk in patients treated with either exenatide once weekly (EQW) or insulin glargine (IG).

**Materials and methods:** Data over 52 wks from 3 controlled trials (DURATION-1, -2, -3) involving 541 EQW patients (54% male, mean±SD baseline age 55±10 y, weight [WT] 93±20 kg, HbA<sub>1c</sub> 8.4±1.1%, diabetes duration 6 y) and 223 IG patients (55% male, mean±SD baseline age 58±9 y, WT 91±16 kg, HbA<sub>1c</sub> 8.3±1.0%, diabetes duration 6 y), were analyzed. Multivariate mixed-effects models were fitted to capture time-varying effects of risk factors on hypoglycaemia incidence (including major, minor and symptomatic), adjusting for age, gender, diabetes duration, concomitant metformin plus sulphonylurea (MET+SU), and longitudinal measures of HbA<sub>1c</sub>, WT, blood pressure, and lipids.

**Results:** MET+SU was used by 26% EQW and 31% IG patients. Hypoglycaemia occurred more often with IG (51% IG and 19% EQW patients experienced ≥ 1 hypoglycaemia episode) and with greater frequency with SU background (SU: 37% EQW and 66% IG; non-SU: 12% EQW and 45% IG). Multivariate analysis showed SU use increased hypoglycaemia risk 3–4 fold for IG and EQW patients. Lower HbA<sub>1c</sub> was more closely associated with

increased incidence and frequency of hypoglycaemia in IG-treated patients than in EQW-treated patients (hypoglycaemia risk with HbA1c  $\leq 6.5$  %: IG, 30%; EQW, 3%). WT change did not influence hypoglycaemia risk with IG patients but EQW-induced WT loss reduced risk (2.5 kg reduction reduced risk 6%).

**Conclusion:** This analysis provides estimates of the effects of time-varying glycaemic control and weight changes on the risk of hypoglycaemia observed with basal insulin and EQW, a long-acting GLP-1 receptor agonist. The analysis confirms the higher risk of hypoglycaemia observed with IG treatment, particularly with more intensified glycaemic control, and that background SU use is a significant driver of hypoglycaemia with both treatments.

### The impact of insulin type on severe hypoglycaemia events requiring inpatient and emergency department care in patients with type 2 diabetes

M. Solomon<sup>1</sup>, S. Vijan<sup>2</sup>, F. Forma<sup>3</sup>, R. Conrad<sup>4</sup>, N. Summers<sup>4</sup>, D. Lakdawalla<sup>5</sup>;

<sup>1</sup>Stanford University School of Medicine, Stanford, <sup>2</sup>University of Michigan School of Medicine, Ann Arbor, <sup>3</sup>sanofi-aventis US, Bridgewater, <sup>4</sup>Precision Health Economics, Los Angeles, <sup>5</sup>University of Southern California, Los Angeles, USA.

**Background and aims:** Although clinical trials suggest that basal analogues have a lower risk of hypoglycemia than other forms of insulin, conclusive data are lacking. We evaluated the risk from different insulin types on severe hypoglycemia (SHG) events requiring inpatient (IP) or emergency department (ED) care in patients with Type 2 diabetes (DM).

**Materials and methods:** Using a large database of privately-insured working-age US adults from 1998–2009, we conducted a retrospective cohort study of DM patients newly started on insulin after at least 6 months of treatment with oral anti-diabetic medications (OADs). We measured SHG events after insulin initiation occurring in the IP or ED setting. Patients were classified into an insulin group based on: (1) the most frequently used insulin type prior to the SHG event for those with SHG events; or (2) the most frequently used insulin overall during our observation period for patients without SHG events. Multivariate Cox proportional hazard regression models assessed the association between insulin type and the risk of subsequent SHG events, controlling for demographics, comorbidities, and the number and type of concomitantly prescribed OADs. Sensitivity analyses of more inclusive definitions of SHG events were conducted.

**Results:** The cohort included 8,626 patients (age 53.5 years; 55% female) with DM followed for an average of 4.0 years after insulin initiation. Of these, 161 (1.9%) had a SHG event at an average of 3.1 years after insulin initiation. Patients with SHG events were slightly older (56.4 years vs. 53.4 years), used a similar number of OADs (1.1 vs. 1.2), and were more likely to have multiple comorbidities compared to those without SHG events. Overall, the most frequently used insulin type was glargine (55%), followed by rapid-acting insulin (23%), isophane insulin (NPH) (9.2%), detemir (6.9%) and premixed insulin (6.6%). In multivariate Cox models, premixed insulin (HR 2.07;  $p < 0.01$ ), isophane insulin (NPH) (HR 2.01;  $p < 0.01$ ), and rapid acting insulin (HR 2.78;  $p < 0.01$ ) had a higher risk of SHG events compared to glargine, and detemir showed a non-significant trend toward more SHG events (HR 1.20;  $p = 0.73$ ). These results were unchanged in sensitivity analyses of more inclusive definitions of SHG events.

**Conclusion:** Among patients with DM who initiate insulin therapy, we found glargine users had lower rates of SHG events requiring IP or ED care compared to users of other insulin formulations. This analysis suggests that differences in the risk of SHG events may exist for various insulin types. Future research should examine the impact and burden of hypoglycemia events of different severity levels.

### Accuracy of nocturnal continuous glucose monitoring (CGM) in type 1 diabetes patients at high risk of severe hypoglycaemia

C. Bay<sup>1</sup>, P. Lommer Kristensen<sup>1</sup>, U. Pedersen-Bjergaard<sup>1</sup>, L. Tarnow<sup>2</sup>, B. Thorsteinsson<sup>1,3</sup>;

<sup>1</sup>Endocrinology Section, Dept. of Cardiology, Nephrology and Endocrinology, Hillerød Hospital, Hillerød, <sup>2</sup>Steno Diabetes Center, Gentofte, <sup>3</sup>Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark.

**Background and aims:** A reliable method to detect biochemical nocturnal hypoglycaemia is needed, especially for patients with recurrent severe hypoglycaemia. Continuous Glucose Monitoring (CGM) may reveal these episodes. This study aimed to evaluate reliability of nocturnal CGM in patients with type 1 diabetes at high risk of severe hypoglycaemia.

**Materials and methods:** We here report CGM data originating from a two-year randomised, open-labelled, crossover multicentre trial designed to investigate the ability of insulin detemir / insulin aspart vs human NPH insulin / soluble insulin to reduce the incidence of severe hypoglycaemia in high-risk patients. Inclusion criteria were age  $\geq 18$  years, type 1 diabetes  $\geq 5$  years,  $\geq 2$  episodes of severe hypoglycaemia during the preceding year, and basal-bolus treatment with human insulin or insulin analogues. The patients underwent CGM (Medtronic MiniMed Guardian® REAL-Time CGMS using Sof-sensor®) for 2 x 2 nights at the diabetes clinic. CGM was calibrated with finger-stick blood glucose measurements before bedtime and blinded to patients and study personnel. Blood was drawn hourly from an i.v. catheter from 23:00 - 7:00 for plasma glucose (PG) measurements, which was considered gold standard. Nocturnal hypoglycaemia was defined by three thresholds:  $<4$ ,  $<3$  and  $<2.2$  mmol/L. A valid episode of hypoglycaemia measured by CGM lasted  $\geq 20$  min.

**Results:** A total of 72 of 110 patients accepted to stay overnight (46 males, age  $54 \pm 12$  years (mean  $\pm$  SD), HbA1c  $8.1 \pm 1.1$ , duration of diabetes  $30 \pm 14$  years), totally 217 nights yielding 1786 paired PG and CGM measurements. Fifty-three per cent of the patients experienced at least one hypoglycaemic night with PG  $< 4$  mmol/L. Prevalences of nocturnal hypoglycaemia according to the three thresholds  $<4$ ,  $<3$  and  $<2.2$  mmol/L were 28%, 16%, 3% for PG and 33%, 12%, 3% for CGM. The sensitivity of CGM according to the three thresholds was 65% (95% CI: 53–77), 40% (24–56) and 17% (0–46), respectively. If only hypoglycaemic nights were taken into account, CGM missed detection of 35% of hypoglycaemia  $<4$ , 60%  $<3$  and 83%  $<2.2$  mmol/L. The correlation coefficient between plasma glucose and CGM recordings was 0.82 (Spearman's rho;  $p < 0.001$ ). Bland-Altman analysis demonstrated that CGM on average underestimated PG by 1.1 mmol/L (0.9–1.2;  $p < 0.001$ ). Of all the paired values 94% were within 95% CI limits, however 2 SD were 5 mmol/L. The mean absolute relative difference (MARD) (%) was higher in the hypoglycaemic range ( $\leq 3.9$  mmol/L) compared to the normo- and hyperglycaemic ranges (4–9.9 mmol/L and  $\geq 10$  mmol/L) as determined by one-way ANOVA ( $p < 0.001$ , Bonferroni correction): 45 (37–53), 23 (22–25) and 20 (19–21), respectively.

**Conclusion:** Reliability of CGM using Sof-sensor® for detecting nocturnal hypoglycaemia in type 1 diabetic patients at high risk of severe hypoglycaemia is inadequate. However, CGM may benefit some high-risk patients since it provides comprehensive night-time glucose profiles and since nocturnal hypoglycaemia is usually unrecognized.

### Characteristics and costs of individuals experiencing severe hypoglycaemia requiring emergency ambulance assistance in the community

K. Khunti<sup>1</sup>, H. Fisher<sup>2</sup>, S. Paul<sup>3</sup>, I. Mohammad<sup>4</sup>, M.J. Davies<sup>5</sup>, A.N. Siriwardena<sup>6</sup>;

<sup>1</sup>Department of Health Sciences, University of Leicester, UK, <sup>2</sup>School of Social and Community Medicine, University of Bristol, UK, <sup>3</sup>Queensland Clinical Trials and Biostatistics Centre, University of Queensland, Brisbane, Australia, <sup>4</sup>East Midlands Ambulance Service NHS Trust, Nottingham, UK, <sup>5</sup>Department of Cardiovascular Sciences, University of Leicester, UK, <sup>6</sup>School of Health and Social Care, University of Lincoln, UK.

**Background and aims:** Hypoglycaemia causes considerable a burden to individuals the healthcare providers. The aim of this study was to examine clinical

cal characteristics of individuals requiring emergency medical assistance by ambulance services for an episode of severe hypoglycaemia and to estimate provider costs of hypoglycaemia.

**Materials and methods:** Routinely collected information was retrieved for all episodes of severe hypoglycaemia attended to by the emergency ambulance services for a population of 367,051 people, including 75,603 people with diabetes, in Nottinghamshire and Derbyshire, UK, between 01/11/10 to 28/02/11. A total of 90,435 emergency calls were received in the study period, of which 523 (0.6%) were recorded as severe hypoglycaemia. The time to response, on-site treatment and hospitalisation were recorded along with standard clinical and blood glucose (BG) measures. Ambulance services costs were calculated.

**Results:** The mean (SD) [proportion  $\leq$  3.2 mmol/L] pre and post-treatment BG levels were 1.9 (0.9) mmol/L [92%] and 6.5 (3.1) mmol/L [3%] respectively, 74% were under insulin treatment, 28% had nocturnal hypoglycaemia, and 153 (32%) individuals were transported to hospital. Lower pre-treatment BG ( $p < 0.01$ ) and Glasgow Coma Scale scores ( $p = 0.05$ ) were observed in insulin treated individuals in comparison to non-insulin treated individuals. No significant differences in individual characteristics were observed for other clinical measurements: post-treatment blood glucose ( $p = 0.39$ ), systolic blood pressure ( $p = 0.28$ ), diastolic blood pressure ( $p = 0.64$ ) and heart rate ( $p = 0.93$ ). Non insulin treatment was an independent predictor of transportation to hospital ( $p < 0.01$ ). Median time from allocation of call to departure of scene by ambulance services was 39 and 59 minutes for those transported and not transported to hospital respectively, translating to costs of £92 and £139 respectively. The median time from allocation to handing over patients to emergency staff was 75 minutes, equating to a cost of £176.

**Conclusion:** The majority of cases of severe hypoglycaemia are successfully treated at the scene by the emergency ambulance services. Insulin treated and non insulin treated individuals do not differ by clinical characteristics, however non insulin treated individuals were more likely to be transported to hospital. Further studies are needed into the effect of prehospital ambulance care by treatment type on subsequent outcomes.

## PS 042 Hypoglycaemia: mechanisms and effects

622

### Recurrent hypoglycaemia increases microRNA expression in the anterior cingulate cortex of brain

W.J. Marsh<sup>1</sup>, E. Ogunnowo-Bada<sup>2</sup>, C.H. Riches<sup>2</sup>, G. Yeo<sup>1</sup>, M.L. Evans<sup>2</sup>;

<sup>1</sup>Department of Clinical Biochemistry, <sup>2</sup>Department of Medicine, Institute of Metabolic Science, Cambridge, UK.

**Background and aims:** Some patients with type 1 diabetes (T1D) lose counterregulatory responses (CRR) to low blood glucose, associated with hypoglycaemia unawareness and increased risk of severe hypoglycaemia. Although the mechanisms remain unclear, hypoglycaemia itself can lead to down-regulation of CRR- a type of "stress desensitisation". We have recently implicated the anterior cingulate cortex (ACC), part of the brain's limbic system which regulates stress responses, in this process. Specifically, hypoglycaemia-induced activation of ACC is lost following recurrent hypoglycaemia (RH). We hypothesised that recurrent episodes of hypoglycaemia would result in discrete changes in gene expression within the ACC, explaining this loss of activation.

**Materials and methods:** 2 groups of chronically-catheterised (carotid and jugular) Sprague-Dawley rats underwent 3 sequential days of s.c. insulin (10/8/6 U/kg Humulin S) with regular sampling of plasma glucose and dextrose infusion as needed. One group was allowed to fall into hypoglycaemic range ( $2.7 \pm 0.1$  mM;  $n = 5$ ) on each of the 3 study days. A control group was maintained at euglycaemia ( $7.4 \pm 0.2$  mM;  $n = 5$ ). Of note, this study design ensures that exposure to exogenous insulin was matched between both groups. The morning following the last insulin injection, brains were harvested, the ACC micro-punched from frozen brain slices, and RNA collected for hybridisation on Affymetrix Rat Gene ST 1.0 microarrays. CEL files were analysed on Genespring 11. Genes were considered significantly altered at  $P > 0.05$  and fold change  $> 1.1$ .

**Results:** In the ACC, 366 genes were up-regulated and 420 genes down-regulated after RH, mostly with relatively subtle alterations in keeping with a physiologically-relevant (mal)adaptation. Of note, 6 of the 9 genes showing the greatest increase with RH were micro-RNAs, a class of regulatory RNA involved in silencing gene expression. In total, 17 up-regulated and 5 down-regulated species encoded micro-RNAs.

**Conclusion:** In summary, RH led to subtle changes in gene expression including increases in micro-RNA in the ACC, a stress regulatory area. Our data suggest that loss of CRR defences against hypoglycaemia in diabetes might be a result of novel epigenetic changes within the brain's stress circuitry.

**Effect of hypoglycaemia on QT interval, parameters of heart rate variability and frequency of arrhythmias in children and adolescents with type 1 diabetes mellitus**

D. Laptev, T. Kuraeva, V. Peterkova;

Endocrinology Research Center, Moscow, Russian Federation.

**Background and aims:** Hypoglycemia can be associated with the development of life-threatening arrhythmias. The main aim of this study was to determine effect of hypoglycemia on QT interval, heart rate variability (HRV) parameters and frequency of arrhythmias in children and adolescents with type 1 diabetes mellitus (T1DM).

**Materials and methods:** The study included 107 young patients (aged 6–18 years) with T1DM. All participants underwent simultaneous continuous ECG (Holter) and glucose (CGM) monitoring for 24-hours. Automatic calculation of QTc and HRV parameters (SDNN, RMSSD) were performed. All data were averaged for 5 minutes synchronously with CGM. Patients with episodes of hypoglycemia (blood glucose less than 3.5 mmol/l) during the day (7:00–23:00) and night (23:00–7:00) were defined. In these patients length of QTc and RR intervals, parameters of HRV and arrhythmias during hypo- and normoglycemia (BG 5–15 mmol/l) were compared.

**Results:** There were 24 episodes of nocturnal hypoglycemia in 17 participants (15.6%) and 45 episodes of diurnal hypoglycemia in 34 participants (31.8 %). During episodes of nocturnal hypoglycemia there were lengthening of QTc interval (439 vs. 424 ms;  $P<0.05$ ) and reduction in HRV parameters (SDNN

68 vs. 90 ms and RMSSD 48 vs. 79 ms;  $P<0.05$ ) w/o significant increase in heart rate (69 vs. 68 beats/min;  $P=0.29$ ). Same except for the HR was during the day (hypoglycemia vs. normoglycemia respectively: QTc interval 435 vs. 422 ms; SDNN 55 vs. 73 ms; RMSSD 26 vs. 45 ms; heart rate 94 vs. 90 beats/min;  $p<0.05$ ). There were no differences in occurrence of arrhythmia during the night. However daytime frequency of ventricular ectopic events was higher during episodes of hypoglycemia.

**Conclusion:** During episodes of hypoglycemia observed prolongation of the QTc interval, reduction in HRV and there may be increased frequency of arrhythmias in daytime.

## 624

**Gastric bypass surgery is associated with a high risk of hypoglycaemia in morbid obesity**

J.M. Brix<sup>1</sup>, H.P. Kopp<sup>1</sup>, M. Schermann<sup>2</sup>, G.H. Scherthaner<sup>3</sup>, G. Scherthaner<sup>1</sup>;

<sup>1</sup>Department of Medicine I, Rudolfstiftung Hospital, <sup>2</sup>Department of Surgery, Rudolfstiftung Hospital, <sup>3</sup>Department of Medicine II, Medical University of Vienna, Austria.

**Background and aims:** Gastric Bypass (GB) surgery is believed to have the best long term results after bariatric surgery. However, detailed investigations about the risk of hypoglycaemia following various surgical interventions are not available. Thus, we performed a prospective study in a large cohort of patients with morbid obesity (MO).

**Materials and methods:** In total 1127 patients with MO (mean BMI: 43.7±9.4 kg/m<sup>2</sup>; mean age: 38 ±11 years; 80.6% females) were studied. In a longitudinal study 175 patients were evaluated before and 2 years after GB. All patients underwent an oral glucose tolerance test (OGTT; 75g glucose) with measurements of blood glucose (BG) and insulin levels. Hypoglycemia was defined as a BG level ≤50 mg /dl. HOMA-insulin resistance was calculated.

**Results:** Before surgery only 8 out of the 1127 (0.007%) patients showed a hypoglycemic event during the OGTT. In patients included in the longitudinal study hypoglycemia was also rather low (0.02%) before surgery, but post-surgery 72 (22.9%) out of the 314 patients showed a post-challenge BG level ≤50 mg /dl (BG range 20–50mg/dl). In the group of patients who underwent GB surgery (n=175), hypoglycemia was present in 57 patients (32.6%); in the Sleeve Gastrectomy group (n=72), 14 patients (19.4%) were suffering hypoglycaemia but only one patient (2.3%) presented with hypoglycemia in the Gastric Bypass group (n=44). Interestingly none of the patients who had vertical banded gastroplasty (n=23) had hypoglycemia in the oGTT. Patients presenting with hypoglycemia lost more weight (46±16kg vs 40±18kg;  $p=0.016$ ) and had a greater loss in BMI (16.0±5.6kg/m<sup>2</sup> vs 14.1±6.2kg/m<sup>2</sup>;  $p=0.038$ ) than patients without hypoglycemia. After surgery, regarding the oGTT, differences in patients with or without hypoglycaemia are depicted in table1.

**Conclusion:** This is the first prospective study indicating a much higher prevalence of severe hypoglycemia (22.9%) after bariatric surgery, especially after Gastric Bypass surgery. The risk for hypoglycemia is particularly high in those patients with a greater weight loss associated with a low insulin-resistance state but still presenting with high post-challenge insulin levels. In conclusion, a systematic evaluation of glucose and insulin levels after an OGTT 2 years post-surgery may help to identify patients at increased risk for severe hypoglycemia.

Table 1

	Hypoglycemia	No Hypoglycemia	p-value
Glucose fasting, mg/dl	75±7	83±10	$p<0.001$
Glucose 1-hour postprandial, mg/dl	147±48	139±48	$p=0.303$
Glucose 2-hour postprandial, mg/dl	40±7	83±28	$p<0.001$
Insulin fasting, µU/ml	6.7±3.0	10.5±7.1	$p<0.001$
Insulin 1-hour postprandial, µU/ml	162.8±109.3	95.0±73.9	$p<0.001$
Insulin 2-hour postprandial, µU/ml	10.2±7.3	27.7±31.8	$p<0.001$
HbA1c, %	5.3±0.4	5.3±0.3	$p=0.240$
HOMA-InsulinResistance	1.2±0.6	2.2±1.6	$p<0.001$

## 625

**Mild familial hyperinsulinaemic hypoglycaemia due to duplication of the SLC16A1 gene**H.U. Irgens<sup>1,2</sup>, T.T.V. Hoang<sup>1,3</sup>, M.S. Strøm<sup>1,2</sup>, A. Molven<sup>4,5</sup>, S. Johansson<sup>1,3</sup>, P.R. Njølstad<sup>1,2</sup><sup>1</sup>Department of Clinical Medicine, University of Bergen<sup>2</sup>Department of Pediatrics, Haukeland University Hospital, <sup>3</sup>Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, <sup>4</sup>The Gade Institute, University of Bergen, <sup>5</sup>Department of Pathology, Haukeland University Hospital, Bergen, Norway.

**Background and aims:** Despite successes in identifying genetic causes for hyperinsulinemic hypoglycemia of infancy (HI), only part of the heritable component of this disease has thus far been explained. We hypothesized that copy number variation (CNV) may be responsible for some of the unexplained variation and screened a selected patient material for CNVs.

**Material and methods:** We screened nine subjects from the Norwegian Hypoglycaemia Registry for possible CNVs. The subjects were negative for mutations in the ABCG8, KCNJ11, HADH, HNF4A and GCK genes. Affymetrix 6.0 microarray was used in the CNV screening. Deletions were checked against normal variants generated from 1100 subjects. We collected blood samples and clinical information from members of affected families to look for segregation between CNVs and hypoglycaemia.

**Results:** We identified a duplication on chromosome 1 containing the complete SLC16A1 gene in one family. This duplication was not found in our list of normal variants. Information was obtained from 27 family members in three generations. Blood samples were obtained from 10 family members. In the third generation, 4 children had observed episodes of hypoglycaemia, one also with hyperinsulinemic hypoglycaemia. Neither of the children needed medical intervention and symptoms seem to weaken with increasing age. All had duplication of SLC16A1. In the second generation no episode of hypoglycaemia had been observed. All affected and their parents had increased birth weight, mean 4350g. No family members reported histories of exercise-induced hypoglycaemia.

**Conclusion:** SLC16A1 encodes the Monocarboxylate Transporter 1 and failed silencing of this molecule in pancreatic beta cells has been linked to physical exercise-induced hypoglycaemia. We found a duplication of SLC16A1 in a family with mild hyperinsulinemic hypoglycaemia. The birth weight was increased in affected family members indicating prenatal hyperinsulinism. There was, however, no evidence of exercise-induced hypoglycaemia. This indicates a different molecular mechanism involved in this family by which increased gene dosage might lead to a mild hyperinsulinemic hypoglycaemia only.

## 626

**Increased risk of severe hypoglycaemic events with increasing frequency of non-severe hypoglycaemic events in patients with type 1 and type 2 diabetes**S. Sreenan<sup>1</sup>, M. Andersen<sup>2</sup>, B.L. Thorsted<sup>2</sup>, M.L. Wolden<sup>2</sup>, M. Evans<sup>3</sup>,<sup>1</sup>Department of Endocrinology, Connolly Hospital, Dublin, Ireland, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>3</sup>Llandough hospital, Cardiff, UK.

**Background and aims:** Severe hypoglycaemic events (SHE) are associated with significant morbidity and mortality, and resultant costs. However, non-severe hypoglycaemic events (NSHE) - despite being more common than SHE - have been less explored, primarily due to an inherent difficulty in measuring their frequency and impact in the real world situation. The aim of this analysis was to investigate the association between reported rates of NSHE and SHE among patients with type 1 (T1DM) and type 2 (T2DM) diabetes mellitus enrolled in the PREDICTIVE study, to establish the odds ratio of experiencing a SHE based on frequency of NSHE.

**Materials and methods:** PREDICTIVE was a global, prospective, observational study. Patients with T1DM (n=7,420) or T2DM (n=12,981), starting treatment with insulin detemir, reported the number of NSHE and SHE experienced during the 4 weeks prior to baseline and follow-up visits (mean 14.4 weeks). SHE were defined as an episode with symptoms of neuroglycopenia, in which the patient was unable to treat himself/herself and third-party intervention was needed, and where the patient had one of the following characteristics: (i) blood glucose <2.8 mmol/L (<50 mg/dL) or (ii) reversal of symptoms after food intake, glucagon or intravenous glucose administration. Confirmed hypoglycaemic events where third-party assistance was not

required were classified as NSHE. Hypoglycaemic events were classified by severity and frequency (NSHE: 0, 1–4, ≥5) (SHE: 0, vs. ≥1). Chi-Square test was used to investigate the link between NSHE and SHE. Logistic regression was used to determine the odds ratio of experiencing ≥1 SHE, in patients having 1–4 or ≥5 NSHE versus those having 0. The logistic regression model controlled for baseline covariates.

**Results:** Baseline demographics (means ±SD) were age, 41.4 ± 16.8 years, duration of diabetes 16.4 ± 12.5 years, BMI 25.2 ± 4.5 kg/m<sup>2</sup> for T1DM, and, 60.6 ± 10.8 years, 11.2 ± 7.5 years and 30.9 ± 5.9 kg/m<sup>2</sup> for T2DM. HbA<sub>1c</sub> at baseline was 8.3 ± 1.7% and 8.6 ± 1.6% in patients with T1DM and T2DM respectively. At follow-up, overall rates of hypoglycaemia were significantly lower for both patients with T1DM and T2DM initiating insulin detemir compared with baseline (*p*<0.0001). There was a statistically significant association between the frequency of NSHE and the experience of SHE in patients with T1DM and T2DM, respectively, at both baseline and follow-up (*p*<0.0001). The odds ratio of experiencing ≥1 SHE increased with frequency of NSHE, for both T1DM and T2DM patients (Table).

**Conclusion:** These observational data, in a large cohort of people with diabetes, confirm a significant association between the frequency of NSHE and subsequent SHE, providing both clinical and economic rationale for the reduction of hypoglycaemic events regardless of severity. Future analyses should aim to define the factors that explain the relationship between NSHE and SHE.

Group/time point	Number of NSHE	Number of patients	Odds ratio of experiencing ≥1 SHE, 95% CI	
T1DM: Baseline n=7,399	0	3,224	1	–
	1–4	2,457	2.07	1.72, 2.49
	≥5	1,718	2.31	1.87, 2.82
T2DM: Baseline n=12,966	0	10,659	1	–
	1–4	1,818	11.10	8.91, 13.81
	≥5	489	15.36	11.47, 20.58
T1DM: Follow-up n=6,837	0	4,190	1	–
	1–4	1,895	2.21	1.51, 3.22
	≥5	752	3.78	2.47, 5.80
T2DM: Follow-up n=12,368	0	11,322	1	–
	1–4	912	16.65	8.66, 32.02
	≥5	134	21.74	7.17, 65.91

CI, Confidence interval; NSHE, non-severe hypoglycaemic event; SHE, severe hypoglycaemic event; T1DM, type 1 diabetes mellitus; T2DM, type 2 diabetes mellitus

Clinical Trial Registration Number: NCT00659295

**Reduction of hypoglycaemia with insulin pump suspension and role of antecedent hypoglycaemia on future hypoglycaemic inductions: ASPIRE study**S.K. Garg<sup>1</sup>, R.L. Brazg<sup>2</sup>, T.S. Bailey<sup>3</sup>, B.A. Buckingham<sup>4</sup>, D.C. Klonoff<sup>5</sup>, J. Shin<sup>6</sup>, J.B. Welsh<sup>6</sup>, F.R. Kaufman<sup>6</sup>,<sup>1</sup>Barbara Davis Center, University of Colorado Denver, Aurora, USA,<sup>2</sup>Rainier Clinical Research Center, Renton, USA, <sup>3</sup>AMCR Institute, Inc.,Escondido, USA, <sup>4</sup>Stanford University, Palo Alto, USA, <sup>5</sup>San Mateo, Mills-Peninsula Health Services, San Mateo, USA, <sup>6</sup>Medtronic, Inc., Northridge, USA.

**Background and aims:** Automatic insulin pump suspension in response to sensor-detected low glucose value may safely and effectively reduce hypoglycemia. The ASPIRE study examined the utility of the low glucose suspend (LGS) feature in hypoglycemia induced by overnight fasting and exercise and the effect of the order of experiments on the duration of hypoglycemia.

**Materials and methods:** Fifty insulin pump users (56% male, mean [±SD] age 34.3±12.4 yr, BMI 26.9±4.3 kg/m<sup>2</sup>, A1C 7.9±0.6%) exercised after an overnight fast until their YSI glucose value was <85 mg/dL with LGS-ON (set to suspend insulin for 2 hours at sensor glucose values ≤70 mg/dL) and with LGS-OFF. Subjects were randomly assigned to Group A (LGS-ON first) or

Group B (LGS-OFF first). A successful experiment was defined by YSI glucose values 50 mg/dL with an observation period of up to 4 hours that was not interrupted by symptomatic hypoglycemia or protocol deviations. After a successful experiment and a washout period of at least 3 days, subjects repeated the experiment with the opposite LGS setting.

**Results:** Of the 134 experiments, 98 were successful (48 LGS-ON and 50 LGS-OFF). Of the 36 unsuccessful experiments, 17 were due to YSI values falling below 50 mg/dL, 14 were due to YSI values not reaching <70 mg/dL, and 5 were due to protocol deviations. The mean duration of hypoglycemia in the 98 successful experiments was significantly less with LGS-ON compared to LGS-OFF ( $138.5 \pm 76.68$  vs.  $170.7 \pm 75.91$  min,  $p=0.006$ ). Mean nadir ( $59.5 \pm 5.72$  vs.  $57.6 \pm 5.69$  mg/dL,  $p=0.015$ ) and mean end-observation YSI glucose values ( $91.4 \pm 41.84$  vs.  $66.2 \pm 13.48$  mg/dL,  $p<0.001$ ) were both higher with LGS-ON than with LGS-OFF. The duration of hypoglycemia in successful LGS-ON experiments was 63.7 min less for Group A than for group B ( $p<0.01$ ). The number of inductions prior to a successful LGS-ON experiment was lower for Group A than for group B ( $0.36 \pm 0.64$  vs.  $1.57 \pm 0.84$ ,  $p<0.001$ ), as was the cumulative duration of antecedent hypoglycemia (Table). The difference in hypoglycemia duration between Groups A and B was not attributable to changes in sensor glucose rates of change, the duration of exercise, or  $AUC<70$  mg/dl in the 2 days before the successful induction (all  $p>0.3$ ).

**Conclusion:** The ASPIRE study showed that automatic insulin pump suspension reduces the duration and severity of hypoglycemia induced by overnight fasting and exercise. Its crossover design highlights that recent antecedent hypoglycemia significantly increases subsequent induced hypoglycemia duration.

Table. Hypoglycemia in the ASPIRE study

	Prior Cumulative Hypoglycemia Duration, min	Hypoglycemia Duration in the LGS-ON Experiment, min
Group A (n=25)	$16.6 \pm 57.3$	$107.8 \pm 71.2$
Group B (n=23)	$204.6 \pm 123.7$	$171.5 \pm 67.0$
p value	<0.001	0.003

Hypoglycemia (defined as YSI <70 mg/dL) duration before and during successful LGS-ON experiments in the in-clinic ASPIRE study (mean  $\pm$  SD)

Clinical Trial Registration Number: NCT01148862

## 628

### Hospitalisations due to severe hypoglycaemia in patients with type 2 diabetes: a US national perspective

G. Singh<sup>1</sup>, A. Mithal<sup>2</sup>, A. Mannalithara<sup>1</sup>, A. Sehgal<sup>3</sup>, M. Bron<sup>4</sup>, O. Dabbous<sup>4</sup>, G. Triadafilopoulos<sup>1</sup>

<sup>1</sup>Stanford University, Palo Alto, <sup>2</sup>Institute of Clinical Outcomes Research and Education, Woodside, <sup>3</sup>University of California, Berkeley, <sup>4</sup>Takeda Pharmaceuticals North America, Inc., Deerfield, USA.

**Background and aims:** Hypoglycemia is a major limiting factor in intensive glycemic control for both type 1 and type 2 diabetes. Severe hypoglycemia is associated with increased risk of adverse clinical outcomes, including cardiovascular complications and possibly increased mortality. We examined the prevalence of serious hypoglycemia hospitalizations in patients with Type 2 diabetes in the US community population.

**Materials and methods:** The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the largest inpatient care database in the US and the only database that has information on all inpatient care regardless of insurance status. NIS's large sample size and data sampling techniques allow calculation of national estimates for particular diagnoses and analysis of secular trends. We studied all inpatient hospitalizations in NIS in 2009 with a primary or secondary diagnosis of Type 2 diabetes and hypoglycemia in patients aged 18 years or older and analyzed them as a proportion of total US resident adult population. US population estimates and projections for the resident US population were obtained from the US Census Bureau.

**Results:** In 2009, there were 33.1 million all-cause hospitalizations in the US among patients 18 years or older in 232.5 million person-years of observation. Of these, 7.2 million (21.7%) hospitalizations were for a primary or secondary diagnosis of Type 2 diabetes, providing a rate of 3,096.8 per 100,000 person-years in the US population. In 2009, there were 248,422 hypoglycemia

hospitalizations in type 2 diabetes patients (average age 67.3 years 95% CIs, 50.7% men), accounting for 3.45% of all hospitalizations in these patients (national prevalence rate 106.9 per 100,000 person-years). Hypoglycemia hospitalizations among type 2 diabetes patients resulted in 1.9 million hospitalization-days in 2009 (average per hospitalization 7.58 days, 95% confidence intervals 7.38 - 7.78), at a total cost of \$12.07 billion (average \$48,569 per hospitalization, 95% confidence limits \$45,781 - \$51,537 per day). Medicare and Medicaid programs were responsible for 76.1 % of these hospitalizations and costs. A large percentage of these hospitalizations (87.5%) were considered non-elective. The case-fatality rate was 3.7%, resulting in 9,274 deaths in patients with hypoglycemia and type 2 diabetes in 2009.

**Conclusion:** National US population-level data suggest that hypoglycemia in Type 2 diabetes was associated with 248,422 hospitalizations and 9,274 deaths in 2009, and a total cost of over \$12 billion. These numbers do not include the long-term indirect clinical consequences of hypoglycemia. While aggressive euglycemic control remains important, the clinical and financial implications of severe hypoglycemia are considerable. Careful selection of anti-diabetic drugs, and close monitoring should be considered to reduce the risk of severe hypoglycemia.

## PS 043 Regulation of fatty acid metabolism

629

### Novel metabolic associations with polymorphisms in the nicotinic acid receptor

L. Chamas, M. Neville, F. Karpe;  
OCDEM, University of Oxford, UK.

**Background and aims:** *HCAR2* is the endogenous receptor for nicotinic acid (NA), a potent plasma lipid and lipoprotein modifying drug with potential anti-inflammatory properties that conveys an anti-lipolytic signal in adipose tissue. Homology between this receptor and *HCA1* and *HCA3*, another two G-protein coupled proteins that have arisen by homologous duplication, has led to ambiguous characterization of common genetic variation in the region. We aimed to re-sequence *HCA2* and *HCA3* to uncover missing or mislabelled polymorphisms.

**Materials and methods:** Sixty-four subjects were selected from the Oxford Biobank (<http://www.oxfordbiobank.org.uk/>) with equal gender representation. Long range PCR products were created for each of the receptors from genomic DNA. Specificity of the near-identical gene products was tested by a unique base pair difference in one of the genes. Targeted and specific sequencing of these genes beyond the coding region was undertaken on shorter sequences created from the long product. Identified SNPs from the sequencing effort were genotyped on a larger cohort (n=3,500). Expression analysis of the two genes was also performed from adipose tissue paired biopsies in abdominal and gluteal depots (n=200). Data was analyzed and related to anthropometric and metabolic variables from the Oxford Biobank.

**Results:** Five of the existing SNPs in the dbSNP database were found to be referring to the wrong gene. Eight previously unreported SNPs were detected by resequencing. One SNP in the promoter region of *HCA3* affected gene expression of both genes. There was a difference in *HCA2* gene expression in adipose tissue between genders, depots and BMI groups. Gene expression also negatively correlated with waist circumference ( $r=-0.40$ ,  $p<0.001$ ) and positively with HDL cholesterol ( $r=0.34$ ,  $p<0.001$ ). A new SNP in the *HCA2* promoter showed an association with waist to hip ratio in men (n=1,900,  $p=0.011$ ), a finding that will need confirmation in a larger cohort.

**Conclusion:** Resequencing of *HCA2* and *HCA3* revealed a number of mislabeled and new genetic variants with potentially interesting phenotypic associations relevant to the putative gene function.

### Free fatty acids as possible biomarkers in control and progression of prediabetes to type 2 diabetes

S. Mandal<sup>1</sup>, A. Causevic<sup>2</sup>, M. Malenica<sup>2</sup>, T. Dujic<sup>2</sup>, T. Bego<sup>2</sup>, B. Prnjavorac<sup>3,4</sup>, S. Semiz<sup>2</sup>,

<sup>1</sup>Department for Analytical Chemistry I and II, Faculty of Pharmacy, University of Sarajevo, <sup>2</sup>Department for Biochemistry and Clinical Analysis, Faculty of Pharmacy, University of Sarajevo, <sup>3</sup>Faculty of Pharmacy, University of Sarajevo, <sup>4</sup>General Hospital Tesanj, Tesanj, Bosnia and Herzegovina.

**Background and aims:** High prevalence of type 2 diabetes (T2D) and obesity represents today a global health problem. The fundamental pathophysiological mechanisms related to T2D include insulin resistance and the decline in pancreatic B-cell function that accompanies an increase in visceral obesity. This is followed by the rise in the plasma concentrations of free fatty acids (FFAs), which are associated with an increase in fat mass and insulin resistance. Numerous studies indicate that FFAs may be potential biomarkers and pharmacological targets in T2D management. In this study we have analyzed concentration of FFAs in patients with T2D and prediabetes, in the context of an optimal diabetes control and monitoring.

**Materials and methods:** The study involved 42 healthy subjects, 46 patients diagnosed with prediabetes, and 73 patients with diagnosed T2D. Diabetic patients were recruited at our hospitals. Preparation of samples for fatty acid analysis was done by using a modified protocol of Le Page and Roy, which involved methanolysis of samples at 50°C for 90 minutes, followed by conversion of FFAs to corresponding fatty acid methyl esters. Detection and quantification of FFAs concentration was done by gas chromatography/mass

spectrometry. In total, 19 FFAs were detected with this protocol. All other biochemical analyses, including glucose, glycosylated hemoglobin (HbA1c), cholesterol, and triglycerides levels, were performed by employing standard IFCC methods.

**Results:** Interestingly, differences in levels of individual FFAs, namely C16:0 were evident between T2D patients and control subjects and C14:0 between prediabetic and T2D patients. Our data showed a significant difference in C16:0 FFA levels between patients with poorly and well-controlled diabetes. There was a significant correlation between HbA1c and C16:0 and C18:1 FFA levels in patients with an adequate T2D control, as well as between HbA1c and C16:0 levels in patients with poor control of the disease.

**Conclusion:** Thus, our data suggest that C16:0, C16:1, and C18:1 could be employed as potential biomarkers in progression and optimal control of T2D, while C14:0, C14:1, C16:0, and C16:1 FFAs could be used as potentially relevant biomarkers in prediabetes.

### <sup>13</sup>C-labelled palmitate and metabolomics/lipidomics analyses reveal the fate of free fatty acids in fasting mice

M. Hoene<sup>1,2</sup>, S. Chen<sup>3</sup>, J. Li<sup>3</sup>, E. Schleicher<sup>1,2</sup>, H.-U. Häring<sup>1,2</sup>, G. Xu<sup>3</sup>, C. Weigert<sup>1,2</sup>, R. Lehmann<sup>1,2</sup>;

<sup>1</sup>Internal Medicine IV, Division of Endocrinology, Diabetology, Vascular Medicine, Nephrology and Clinical Chemistry, University Hospital Tuebingen, Germany, <sup>2</sup>Paul Langerhans Institute Tuebingen, Member of the German Diabetes Centre, Institute for Diabetes Research and Metabolic Diseases of the Helmholtz Centre Munich at the University of Tuebingen, Tuebingen, Germany, <sup>3</sup>CAS Key Laboratory of Separation Science for Analytical Chemistry, Dalian Institute of Chemical Physics, Chinese Academy of Sciences, China.

**Background and aims:** During fasting, free fatty acids (FFA) released from adipose triglyceride stores become the major source of energy. Because lipolysis is in excess over utilization, plasma FFA are considerably elevated despite an increased utilization by skeletal muscle and other peripheral tissues. The plasma concentration of acylcarnitines, intermediates of fatty acid oxidation, also increases during fasting and exercise, but it is unclear if they originate from skeletal muscle or from the liver, the key metabolic regulator and short-term buffer for excess circulating FFA. Using a stable <sup>13</sup>C-isotope labelled fatty acid tracer in mice, we tested the hypothesis that excess palmitate is incorporated into acylcarnitines in the muscle and into triglycerides and other lipids in the liver in the fasted state.

**Materials and methods:** Male C57BL/6N mice were fasted for 15 h. A bolus of 20 nmol/kg body weight of [U-<sup>13</sup>C]-palmitate was applied into the caudal vein of the anaesthetised mice. After 10 minutes, plasma, liver and gastrocnemius muscles were obtained. Lipids, acylcarnitines and free fatty acids were extracted and analyzed by UPLC-mass spectrometry for [U-<sup>13</sup>C]-palmitate-derived metabolites. Values are means ± SD from n=7 mice.

**Results:** The amount of [U-<sup>13</sup>C]-palmitate injected was aimed to correspond to the increase in plasma FFA typically caused by 15 h fasting or 1 h of moderately intense running in mice, to a calculated maximal plasma concentration of 300 μmol/L. Ten minutes after the bolus injection, 2.5±0.5 μmol/L free tracer were left in plasma and 39±12 and 14±4 nmol/g<sub>protein</sub> in liver and muscle, respectively. Acylcarnitines derived from the tracer reached a plasma concentration of 0.82±0.18 nmol/L and were considerably higher in muscle than in the liver, 0.95±0.47 versus 0.002±0.001 nmol/g<sub>protein</sub>. Lipids incorporating palmitate tracer were only detectable in the liver, a total of 511±160 nmol/g<sub>protein</sub> as triglycerides and 58±9 nmol/g<sub>protein</sub> as phosphatidylcholine.

**Conclusion:** By using <sup>13</sup>C-labelled palmitate as a tracer, we could show that compared to skeletal muscle, the production of acylcarnitines from long-chain FFA in the liver is negligible. Thus, it can be concluded that the muscle and not the liver is responsible for the increase in plasma long-chain acylcarnitines during fasting. In addition, this tracer study confirmed the central role of the liver as buffering system for the storage of excess fatty acids present in the circulation during fasting and revealed that the bulk of labelled palmitate is incorporated into hepatic triglyceride and phosphatidylcholine.

**A natural compound FST6 regulates glucose and lipid metabolism in adipocytes by inhibiting 11 beta- HSD1 and enhancing AMPK signalling pathway**

S. Huang, H. Zeng, M. Ning, Y. Leng;

Shanghai Institute of Materia Medica, Chinese Academy of Sciences, China.

**Background and aims:** 11 $\beta$ -Hydroxysteroid dehydrogenase type 1 (11 $\beta$ -HSD1) and AMP-activated protein kinase (AMPK) are attractive therapeutic targets of type 2 diabetes and metabolic syndrome. FST6, a nature compound was discovered from our natural products library as a potent 11 $\beta$ -HSD inhibitor, and it could also active AMPK signaling pathway. In the present study, the effects of FST6 on glucose and lipid metabolism in adipocytes were investigated and its possible mechanisms were explored.

**Materials and methods:** Scintillation proximity assay was performed to evaluate inhibition of FST6 against 11 $\beta$ -HSDs from recombinant human and mouse 11 $\beta$ -HSDs. Its 11 $\beta$ -HSD1 inhibitory activity *in vivo* was investigated in C57BL/6J mice. Activation of FST6 on AMPK signaling pathway was investigated by western blot analysis. Glucose uptake and fatty acid oxidation in 3T3-L1 adipocytes were measured. 11-DHC (inactive glucocorticoids), corticosterone (active glucocorticoids) and compound C were used for mechanism exploration.

**Results:** FST6 is a potent and selective 11 $\beta$ -HSD1 inhibitor with the IC<sub>50</sub> of 58.6nM and 17.8nM for human and mouse 11 $\beta$ -HSD1. It also inhibited 11 $\beta$ -HSD1 activity in 3T3-L1 adipocytes with the IC<sub>50</sub> of 2.1 $\mu$ M. Single oral administration of FST6 reduced 11 $\beta$ -HSD1 activity to 67.8% in mesenteric adipose tissue of C57BL/6J mice. FST6 increased AMPK and ACC phosphorylation significantly in 3T3-L1 adipocytes in a dose dependent manner. Moreover, single oral administration of FST6 at dose of 300 mg/kg in C57BL/6J mice increased AMPK and ACC phosphorylation in mesenteric adipose tissue. Both 11-DHC (inactive glucocorticoids) and corticosterone (active glucocorticoids) attenuated insulin stimulated glucose uptake in 3T3-L1 adipocytes. FST6 significantly reversed the impaired insulin stimulated glucose uptake induced by 11-DHC, but not corticosterone. FST6 dose dependently increased free fatty acid oxidation in 3T3-L1 adipocytes after 2 h treatment. This effect could be completely blocked by the pretreatment of Compound C, an AMPK inhibitor.

**Conclusion:** Our results demonstrate that FST6 is a potent and selective 11 $\beta$ -HSD1 inhibitor and activates AMPK simultaneously, which regulates glucose and lipid metabolism in adipocytes. These findings suggest that FST6 may have beneficial effects in the treatment of adipose abnormality in type 2 diabetes and metabolic syndrome.

## 633

**Unravelling eicosanoid action on lipid metabolism and glucose homeostasis during obesity**S. Franckhauser<sup>1,2</sup>, I. Elias<sup>1,2</sup>, T. Ferré<sup>1,2</sup>, S. Muñoz<sup>1,2</sup>, M. Garcia<sup>1,2</sup>, J. Agudo<sup>1,2</sup>, F. Bosch<sup>1,2</sup>;<sup>1</sup>Center of Animal Biotechnology and Gene Therapy, Universitat Autònoma de Barcelona, Bellaterra, <sup>2</sup>CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain.

**Background and aims:** Adipose tissue macrophage infiltration and inflammatory cytokine secretion may play a role in the onset of insulin resistance and atherosclerosis during obesity. Recently, eicosanoids have been described to play an important role in adipose tissue inflammation. It has been observed that expression of arachidonate 5-lipoxygenase-activating protein (Alox5ap) gene, coding for a key protein in eicosanoid synthesis, is increased in adipocytes from human patients with obesity and insulin resistance, and in adipose tissue from obese and insulin resistant mice.

**Material and methods:** Thus, to study the effects of an increase in Alox5ap expression in adipocytes, transgenic mice over-expressing Alox5ap in adipose tissue were generated and characterized.

**Results:** Two transgenic lines were obtained, in which mRNA Alox5ap levels were increased in white and brown adipose tissue. This was parallel to a slight increase in LTB<sub>4</sub> and MCP-1 synthesis in WAT explants from both transgenic lines compared with controls. Moreover, transgenic mice presented decreased body weight and length than control mice and a lower fat pad weight. This was associated with an increase in energy expenditure. Transgenic mice were glucose intolerant, without presenting whole-body insulin resistance, accordingly to a defect in glucose-induced insulin secretion. When challenged a high fat diet, these mice gained less body weight, but similar fat mass and

they remained more insulin sensitive than control mice. This was associated with decreased circulating levels of insulin, free fatty acids, triglycerides and glycerol. In contrast, serum total cholesterol and HDL-cholesterol levels were higher in transgenic mice. In addition, the expression of inflammation markers in adipose tissue was reduced in these mice.

**Conclusion:** These results suggest that Alox5ap overexpression in adipose tissue does not lead to insulin resistance but to defects in insulin secretion and may protect against high fat diet-induced inflammation and insulin resistance.

## 634

**Role of bombesin receptor subtype-3 and its agonist [D-Phe<sup>6</sup>- $\beta$ -Ala<sup>11</sup>,Phe<sup>13</sup>,Nle<sup>14</sup>]bombesin<sub>6-14</sub> in lipid metabolism**Z. Moreno-Villegas<sup>1</sup>, I. Ramos-Álvarez<sup>2</sup>, R. Sanz<sup>1</sup>, R. Jensen<sup>3</sup>, N. González<sup>2</sup>;<sup>1</sup>Metabolism, Nutrition and Hormones, IIS- Fundación Jiménez Díaz,Madrid, Spain, <sup>2</sup>IIS- Fundación Jiménez Díaz, CIBERDEM, Madrid, Spain,<sup>3</sup>National Institutes of Health, Bethesda, USA.

**Background and aims:** Bombesin Receptor Subtype BRS-3 receptor deficient mice develop a mild-late-onset obesity with metabolic alterations, which could be due to impairment in the glucotransporter-4 (glut-4) translocation mechanism in adipocytes. Moreover, we described that BRS-3 gene expression is lower than normal in skeletal muscle of diabetic and/or obese patients and also, in primary cultured myocytes from normal or altered metabolic patients, agonist [D-Phe<sup>6</sup>- $\beta$ -Ala<sup>11</sup>,Phe<sup>13</sup>,Nle<sup>14</sup>]bombesin<sub>6-14</sub> (BRS-3-AP) stimulated glucose transport, glut-4 and BRS-3 expression, kinase phosphorylation level (PKB, MAPKs, p70s6K), PI3K activity and glucose metabolism. Here, in rat adipose tissue without metabolic alterations, we have studied BRS-3 gene expression, characteristics of the receptor signalling pathways by using BRS-3-AP, and explored its effect on lipid metabolism.

**Methods:** Adipocytes were isolated by enzymatic digestion from epididymal fat pads of 10 normal male Wistar rats (200–250 g), kept in a standard chow and water ad libitum. We measured: BRS-3 gene expression -real time-PCR-, MAPKs and p90RSK-1 activity -Western Blot-, lipogenesis as <sup>14</sup>C-Na acetate incorporation into lipids, in cells incubated in BRS-3-AP absence (control) or presence (10<sup>-13</sup>-10<sup>-7</sup> M), and with or without 10<sup>-6</sup> M wortmanin -PI3K/ PKB inhibitor-, 2.5x10<sup>-5</sup> M PD98059 -MAPKs inhibitor-, 10<sup>-7</sup> M rapamycin -p70s6K inhibitor-.

**Results:** We demonstrated by RT-PCR the presence of BRS-3 mRNA, in rat adipose tissue. The synthetic agonist BRS-3-AP caused a lipogenesis concentration-related stimulation, already detected at 10<sup>-11</sup> M (118 $\pm$ 6% control), which achieved significance values (10<sup>-10</sup> M: 128 $\pm$ 7% control, *p*<0.05; 10<sup>-9</sup> M: 136 $\pm$ 5% and 10<sup>-8</sup> M: 168 $\pm$ 18%, *p*<0.02) and was maximal at 10<sup>-7</sup> M (209 $\pm$ 20% control, *p*<0.02). The lipogenic effect of BRS-3-AP (10<sup>-8</sup> M: 164 $\pm$ 13% control, *p*<0.01), not different from that induced by insulin (10<sup>-8</sup> M: 140 $\pm$ 9% control, *p*<0.01) was abolished by the additional presence of wortmanin (108 $\pm$ 5% control) and the same blocking effect was detected in the presence of PD-98059 (104 $\pm$ 11% control). However, rapamycin only partially reduced the effect of the synthetic BRS-3 ligand (113 $\pm$ 5% control, *p*<0.05 vs 10<sup>-8</sup> M BRS-3-AP). BRS-3-AP at 10<sup>-9</sup> M clearly increased (*p*<0.05) MAPKs phosphorylation (p44: 141 $\pm$ 11% control; p42: 230 $\pm$ 40%; *p*<0.05 or lower) like it did 10<sup>-9</sup> M insulin (p44: 144 $\pm$ 9% control; p42: 146 $\pm$ 20%; *p*<0.05). In addition, p90RSK-1 phosphorylation level was significantly (*p*<0.05) increased by the synthetic agonist at 10<sup>-9</sup> M and 10<sup>-8</sup> M (169 $\pm$ 5% control and 171 $\pm$ 21% control, respectively), similar to that induced by 10<sup>-9</sup> M insulin (153 $\pm$ 11% control, *p*>0.05).

**Conclusion:** These results reveal a specific role of BRS-3 in adipose tissue -potential origin of insulin-resistance- and not only describe the lipogenic effect of its synthetic agonist but also, clarify the receptor signalling pathway. These facts points out the receptor, and/or its agonist peptide, as a molecular target in the therapy of diabetes and obesity.

## PS 044 Mechanisms of NAFLD progression

635

### Molecular insights of liver steatosis and inflammation in db/db mice

M.F. Scheerer<sup>1,2</sup>, B. Fridrich<sup>1</sup>, G. Kastenmüller<sup>3</sup>, M. Irmeler<sup>1</sup>, M. Kahle<sup>1</sup>, J. Beckers<sup>1</sup>, K. Suhre<sup>3,4</sup>, H.-W. Mewes<sup>3</sup>, M. Hrabé de Angelis<sup>1,2</sup>, S. Neschen<sup>1,2</sup>; <sup>1</sup>Institute of Experimental Genetics, Helmholtz Zentrum München, Neuherberg/Munich, Germany, <sup>2</sup>German Mouse Clinic, Helmholtz Zentrum München, Neuherberg/Munich, Germany, <sup>3</sup>Institute of Bioinformatics and Systems Biology, Helmholtz Zentrum München, Neuherberg/Munich, Germany, <sup>4</sup>Bioinformatics Core, Weill Cornell Medical College, Doha, Qatar.

**Background and aims:** Leptin receptor (LR) gene polymorphisms have been shown to contribute to the onset of Non-Alcoholic Fatty Liver Disease (NAFLD) in rodents and humans. Aim of the study was to examine the role of a non-functional leptin receptor in a db/db mouse model in the pathophysiology of hepatic steatosis.

**Materials and methods:** BKS.Cg + Leprdb/+ Leprdb (db/db) and BKS.Cg Dock7m +/Dock7m + (wt) mice (n=10 each group) were fed a high fat diet after weaning at an age of three weeks. At 10 weeks of age, mice were fasted for four hours and plasma and organs dissected under isoflurane anesthesia. Besides plasma parameters characterizing organ function, glucose and lipid homeostasis, we compared hepatic gene expression (Illumina) as well as hepatic and plasma metabolite profiles via a non-targeted approach (Metabolon, LC-MS, GC-MS) in both genotypes.

**Results:** After seven weeks of high fat diet feeding, obese db/db mice displayed a pronounced diabetic phenotype compared to lean, wild type controls (db/db vs. WT; HbA1c: 57±7 vs. 21±1 mmol/mol; plasma glucose: 43.1±2.2 vs. 17.0±1.8 mmol/l, plasma insulin: 791±350 vs. 85±11 mol/l). Elevations in plasma CRP (db/db vs. WT; 13.3±1.7 vs. 5.4±0.8 mg/l), triglycerides (db/db vs. WT; 2.6±0.4 vs. 1.3±0.3 mmol/l) and ALT concentrations (db/db vs. WT: 130±51 vs. 29±4 U/l) paralleled pronounced hepatosteatosis (db/db vs. WT; liver triacylglycerol: 1652±149 vs. 295±27 μmol/g). An increase in homocysteine concentrations in presence of decreasing methionine concentrations was detected in db/db mouse livers. Such an alteration in the methionine:homocysteine ratio could impair S-adenosylmethionine (SAM) cycle activity what might result in an increased availability of educts for the rate limiting step of glutathione synthesis - the conversion from cysteine and glutamate to glutamylcysteine. Interestingly, the hepatic transcript of the catalytic subunit of glutamate-cysteine ligase was 3-fold downregulated. This could potentially alter the GSH/GSSG ratio in db/db mouse livers and contribute to oxidative stress and inflammation in hepatosteatosis.

**Conclusion:** A decrease in SAM in liver has been implicated in the initial steps of hepatic steatosis in db/db mice raised on a methionine deficient diet. However, our findings show increased inflammation even when SAM levels remain unaffected. Solely hepatic glutathione concentrations - in absence of alterations in pro-inflammatory arachidonic acid derivative levels - were changed in NAFLD. Thus, our findings indicate that progression from benign to malign NAFLD might depend on a reduced glutathione production rate in mice with impaired signalling through the leptin receptor.

### Astaxanthin reduces hepatic insulin resistance and inhibits the progression of lipotoxic model of nonalcoholic steatohepatitis

T. Ota, Y. Ni, L. Zhan, M. Nagashimada, S. Kaneko;  
Frontier Science Organization, Kanazawa University, Japan.

**Background and aims:** Nonalcoholic steatohepatitis (NASH) and insulin resistance frequently coexists in subjects with obesity and type 2 diabetes. NASH can be defined as a lipotoxic liver injury caused by excess body adiposity. Hepatic inflammation and/or fibrosis could be caused by lipid peroxidation preceded by excessive hepatic lipid accumulation. In our previous study, we developed a cholesterol- and saturated fatty acid-induced model of lipotoxic NASH and revealed that hepatic oxidative stress and insulin resistance promotes hepatic inflammation and fibrosis. Astaxanthin is a carotenoid compound that is known to be approximately 500 times more potent in inhibiting lipid peroxidation than vitamin E *in vitro*. In the present study,

we examined the inhibitory effect of astaxanthin against the progression of NASH to clarify the significance of lipid peroxidation-mediated lipotoxicity and insulin resistance in the pathogenesis of NASH.

**Materials and methods:** 7-week-old C57BL/6 mice were fed on a high-cholesterol/high-fat diet (CL) or a CL diet containing 0.02% astaxanthin (CL + Ax), for a total of 12 weeks. The lipid peroxidation, insulin sensitivity, and inflammatory/stress signal were evaluated.

**Results:** After 8 weeks of feeding, the levels of thiobarbituric acid reactive substances (TBARS) in liver were significantly increased and histological examination revealed hepatic steatosis and inflammation. At week 12, hepatic fibrosis was observed in mice fed CL diet. They showed hyperinsulinemia (CL1.4±0.3 vs normal chow (NC) 0.3±0.1 ng/ml,  $p < 0.05$ ) and glucose intolerance even though weight and adiposity were similar, indicating that mice fed on a CL diet developed NASH associated with insulin resistance. Astaxanthin administration markedly reduced lipid peroxidation and improved glucose intolerance and insulin sensitivity in CL group. CL group had 2.5-fold and 4.1-fold increases in hepatic triglyceride (TG) and total cholesterol (TC) levels compared to NC group; astaxanthin decreased hepatic TG and TC levels by 38% and 46%, respectively (all  $p < 0.05$ ). The  $\alpha$ -SMA positive cell, as an index of activated stellate cells, increased in CL group, but decreased significantly in CL+Ax group. Furthermore, CL treatment led to 1.5-fold and 6-fold increase in TGF- $\beta$  and collagen I mRNA expression, and 4.3-fold increase in hydroxyproline content, whereas astaxanthin administration inhibited fibrosis, lowering the TGF- $\beta$  and collagen I mRNA expression, and hydroxyproline content by 28%, 35%, and 24%, respectively (all  $p < 0.05$ ). Astaxanthin administration in CL-fed mice led to enhanced insulin signal assessed by IR $\beta$  and Akt phosphorylation in the liver. These findings were associated with reduction of ER stress (CHOP/GRP78), attenuation of MAPK (JNK/p38MAPK) and NF- $\kappa$ B activation in liver. Astaxanthin, however, showed little effect on insulin resistance and stress response in the adipose tissue in the CL-treated mice.

**Conclusion:** Hepatic cholesterol and TG accumulation causes excessive lipid peroxidation and the development of insulin resistance, leading to hepatic inflammation and fibrosis. Astaxanthin, a strong antioxidant, inhibits the progression of NASH by attenuating lipid accumulation, lipid peroxidation, and insulin resistance.

### Prep1 deficiency is associated with a reduced hepatic lipogenesis and attenuates methionine choline deficient diet-induced steatohepatitis

S. Cabaro<sup>1</sup>, F. Oriente<sup>1</sup>, A. Liotti<sup>1</sup>, L. Parrillo<sup>1</sup>, T.B. Pagano<sup>2</sup>, O. Paciello<sup>2</sup>, F. Blasi<sup>3</sup>, P. Formisano<sup>1</sup>, F. Beguinot<sup>1</sup>;

<sup>1</sup>DBPCM, University of Naples, <sup>2</sup>DPAH, University of Naples, <sup>3</sup>IFOM (FIRC Institute of Molecular Oncology), Milan, Italy.

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a liver disease frequently associated with the clinical features of metabolic disorders such as insulin-resistance, that causes fat accumulation, inflammation and fibrosis. In fact, several evidences have shown that in presence of insulin-resistance the impairment of the AMPK signaling may be associated with increased lipogenesis and onset of hepatic steatosis. Recent data have suggested the implication of some transcription factors both in insulin-resistance and steatosis. Prep1 is a homeodomain transcription factor belonging to the TALE proteins, which plays an important role in hematopoiesis, organogenesis and development. Previous studies have indicated that Prep1 heterozygous (Prep1<sup>+/+</sup>) mice, which express only 55-57% of protein, have a complex metabolic phenotype with at least two relevant features. One is the presence of smaller but otherwise normally structured islets with reduced fasting and post-loading plasma insulin levels. The second is increased insulin sensitivity in skeletal muscle and in liver which is accompanied by protection from streptozotocin-induced diabetes. In muscle decreased Prep1 levels are followed by an increase of the PGC1 $\alpha$ /Glut4 mediated glucose uptake. In liver, better insulin sensitivity is due to a reduced Shp1 tyrosine phosphatase expression followed by an increase of insulin signaling. In this study we have focused our attention on the role of Prep1 on the regulation of lipogenesis and how this effect could be related to MCD diet-induced NASH.

**Methods and results:** To study the lipogenesis in the liver of the Prep1 heterozygous mice, we have measured triglyceride content both in serum and in liver and hepatic expression of the lipogenic enzyme FAS (Fatty Acid Synthase). Hepatic FAS mRNA levels are significantly decreased. Western Blot analysis have shown increased phosphorylation of PKC $\zeta$ , LKB1, AMPK and ACC, which may control FAS expression and triglycerides production in

Prep1<sup>+/+</sup> mice liver. mRNA and protein levels of the lipid phosphatase SHIP2, an inhibitor of PI3Kinase/PKCzeta signaling, are reduced by 40% in the liver of Prep1<sup>+/+</sup> mice. To understand the potential role of the Prep1-mediated lipogenesis, hepatic steatosis has been induced feeding WT and Prep1<sup>+/+</sup> mice a methionine and choline-deficient (MCD) or a control diet (CD) for 28 days. In Prep1<sup>+/+</sup> mice receiving the MCD diet serum ALT levels are 50% lower than the WT mice. Moreover, hepatic triglyceride content is diminished by 30% at the onset and the outcome of the MCD diet in Prep1<sup>+/+</sup> mice compared to the control littermates, indicating that Prep1 reduction protects in part from hepatic steatosis.

**Conclusion:** All together these data suggest that Prep1-deficiency reduces lipotoxicity by the increasing PKCzeta/AMPK signaling and ameliorates NASH giving a rationale to investigate Prep1 as possible new therapeutic agents in preventing fatty liver progression to NASH.

## 638

### Effect of acute hepatic overexpression of SIRT3 on metabolic parameters in short-term high fat fed mice

B. Osborne, M. Montgomery, J. Reznick, G.J. Cooney, N. Turner; Garvan Institute of Medical Research, Sydney, Australia.

**Background and aims:** Dysregulated mitochondrial metabolism has been linked with several human disorders, including insulin resistance and type 2 diabetes. Recent studies have shown that the sirtuin family of NAD<sup>+</sup>-dependent deacetylase enzymes play an important role in the regulation of mitochondrial function. In particular, SIRT3 has been shown to directly regulate the activity of a range of mitochondrial proteins, suggesting a key role for this enzyme in the regulation of energy metabolism. SIRT3 knockout mice are insulin resistant when maintained on a low-fat chow diet and display accelerated development of the metabolic syndrome when exposed to a long-term high fat diet (HFD). Given the detrimental effects of SIRT3 deletion, the aim of the current study was to determine if hepatic overexpression of SIRT3 could protect against metabolic defects induced by high fat feeding in mice.

**Materials and methods:** C57BL6 mice were subjected to hydrodynamic tail vein injection of a plasmid containing hSIRT3-FLAG, to produce specific overexpression in the liver. A control group was similarly injected with the plasmid encoding the empty vector. Mice were then maintained on either a chow or HFD for 3 weeks and glucose tolerance was assessed using an intraperitoneal glucose tolerance test (2g/kg). Expression of SIRT3 was assessed by real-time PCR and western blot and liver triglycerides were also measured.

**Results:** Liver Sirt3 mRNA expression was increased approximately 9-fold over control ( $4.6 \pm 0.113$  vs.  $39.7 \pm 0.769$  control vs. SIRT3-FLAG,  $p < 0.001$ ). Overexpression at the level of protein was evident by an additional band directly above the endogenous mSIRT3 protein band on a western blot, corresponding to human SIRT3-FLAG (90% increase in total SIRT3 protein by densitometric analysis,  $p < 0.01$ ). At 3 weeks, control mice fed the HFD exhibited a 2.5-fold ( $p < 0.01$ ) increase in the mass of the epididymal fat pad and displayed a significant impairment in glucose tolerance compared to chow-fed animals (~2-fold increase in incremental area under the curve during the glucose tolerance test,  $p < 0.001$ ). Furthermore, liver triglyceride levels were significantly higher in fat-fed mice ( $8.5 \pm 1.37$  vs.  $17.6 \pm 2.25$   $\mu\text{mol/g}$ ,  $p < 0.01$ ). Despite significant increases in expression at both the mRNA and protein level, mice with hepatic overexpression of SIRT3 displayed similar impairments in glucose tolerance and a comparable degree of triglyceride accumulation in response to the HFD as control animals.

**Conclusion:** While previous studies in knockout animals show detrimental metabolic effects, current results suggest that overexpression of the mitochondrial deacetylase enzyme SIRT3 in mouse liver in vivo does not protect against hepatic lipid accumulation and glucose intolerance induced by a short-term HFD. It remains possible that prolonged SIRT3 overexpression may have beneficial metabolic effects in long-term high fat feeding or that other components of the sirtuin pathway (e.g. NAD<sup>+</sup> availability) are critical for sirtuin regulation of metabolism.

## 639

### Both lipid and protein phosphatase activities of PTEN control hepatic gluconeogenesis and lipid storage in the liver

L. Bourgoïn<sup>1</sup>, M. Peyrou<sup>1</sup>, S. Clément<sup>2</sup>, F. Negro<sup>2,3</sup>, M. Foti<sup>1</sup>;

<sup>1</sup>Cell Physiology and Metabolism, University Medical Center, <sup>2</sup>Division of Clinical Pathology, University Medical Center, <sup>3</sup>Division of Gastroenterology and Hepatology, University Hospital, Switzerland.

**Background and aims:** PTEN is one of the most important tumor suppressor identified to date and an important negative regulator of PI3K signaling. It functions as a dual phosphatase being capable of dephosphorylating both phosphoinositides, thereby antagonizing PI3K signaling, and proteins. Liver-specific PTEN knockout mice develop within months the whole spectrum of non-alcoholic fatty liver diseases and hepatocellular carcinoma with ageing, but paradoxically, these mice have an enhanced peripheral glucose tolerance. We further demonstrated that with obesity and the metabolic syndrome, PTEN expression is decreased in the liver of different rat models and in human subjects. This study aims now at understanding the molecular mechanisms by which PTEN deficiency improves systemic glucose tolerance, while promoting aberrant lipid storage in the liver.

**Materials and methods:** 4-month old AlbCre<sup>+/+</sup>/PTEN<sup>flx/flx</sup> mice and littermate controls were subjected to metabolic tests and ex-vivo analyses of liver tissues. In parallel, insulin signaling and the lipid metabolism was investigated in Huh-7 cells transduced with retroviral constructs expressing either shRNAs against PTEN, or dominant negative mutants of PTEN impaired in their lipid or protein phosphatase activities.

**Results:** 4-months old mice lacking PTEN specifically in the liver displayed abnormal ALT/AST serum levels, a marked hepatomegaly (liver weight:  $+75.7 \pm 12\%$ ,  $p < 0.001$ ) and steatosis (liver triglyceride:  $+426.7 \pm 11\%$ ,  $p < 0.001$ ), but an increased peripheral glucose tolerance. Hepatic deficiency of PTEN did not alter the body weight and the ratio of lean vs fat mass, the food/water intake, locomotor activity, thermoregulation, and more generally, energy expenditure. However, these mice were hypoglycemic in fasted state ( $-34.6 \pm 10\%$ ,  $p < 0.5$ ) and had a strong inhibition of gluconeogenesis in response to pyruvate challenge. Inhibition of gluconeogenesis was associated with an increased Akt activity, although insulin receptors and insulin receptor substrates (IRSs) proteins expressions/activities were strongly downregulated. Surprisingly, only inhibition of the protein, but not the lipid, phosphatase activity of PTEN, using dominant negative mutants, was found to induce steatosis in Huh-7 cells. In contrast, Akt activity was only enhanced by mutants impairing the lipid phosphatase activity of PTEN.

**Conclusion:** Inhibition of hepatic gluconeogenesis contributes to the increased glucose tolerance in liver-specific PTEN knockout mice. Whereas the lipid phosphatase activity of PTEN controls Akt activation, the development of steatosis in hepatocytes is associated with deficiency in the protein phosphatase activity of PTEN.

### Deletion of the small heterodimer partner gene protects against fatty liver and dyslipidaemia, but not obesity and glucose intolerance in C57BL/6J mice fed a high-fat diet

K. Iizuka, W. Wudelehu, R. Tomita, H. Tsuchida, Y. Horikawa, J. Takeda; Department of Diabetes and Endocrinology, Gifu university, Japan.

**Background and aims:** The orphan nuclear receptor small heterodimer partner (SHP) has an important role in the regulation of metabolic pathways that are involved in hepatic bile acid production as well as in lipid and glucose homeostasis. However, the role of SHP in metabolic syndrome is not clear. We examined the effects of homozygous SHP knockout (SHP<sup>-/-</sup>) on metabolic syndrome development in C57BL/6J mice. Moreover, we examined whether glucagon-like peptide-1 (GLP-1) analogs affect the metabolic changes in SHP<sup>-/-</sup> mice fed a high-fat diet.

**Materials and methods:** From 13 weeks of age, wild-type (WT) and SHP<sup>-/-</sup> C57BL/6J mice were fed a high-fat diet [Quick Fat diet™ (CLEA Japan, Inc., Tokyo, Japan)] containing 14% fat, 25% protein, and 46.3% starch. At 30 weeks of age, the GLP-1 analog, liraglutide (50  $\mu\text{g/kg}$  body weight/day) or saline (placebo) was administered for 5 days. We examined glucose tolerance, lipid profiles, body weight, histology of liver sections, and mRNA levels.

**Results:** Body weights were similar between WT and SHP<sup>-/-</sup> C57BL/6J mice fed a high-fat diet (WT:  $34.56 \pm 2.89$  g vs SHP<sup>-/-</sup>:  $34.38 \pm 3.43$  g). However, liver weights in SHP<sup>-/-</sup> mice were much lower than those in WT mice (WT:

4.69 ± 0.20% vs SHP-/-: 3.80 ± 0.22%). Blood glucose levels were similar between SHP-/- and WT mice. Interestingly, hepatic fatty changes in histological sections were not detected in SHP-/- mice fed a high-fat diet. Fasting total cholesterol levels in SHP-/- mice were much lower than those in WT mice (WT: 126.18 ± 7.56 mg/dl vs SHP-/-: 81.09 ± 14.27 mg/dl, respectively). In contrast, fasting triglyceride levels in SHP-/- mice were higher than those in WT mice (WT: 98.9 ± 16.41 mg/dl vs SHP-/-: 110.85 ± 9.36 mg/dl). In the livers of SHP-/- mice fed a high-fat diet, SHP mRNA levels were not detected, farnesoid X receptor mRNA levels increased 1.6 times, and peroxisome proliferator-activated receptor-γ (PPARγ) mRNA levels decreased by 40% compared to WT mice fed a high-fat diet. Moreover, cytochrome P450 A1 (Cyp7A1) mRNA levels, by which cholesterol is converted into bile acid, were increased 13 times in SHP-/- mice. Finally, in SHP-/- mice fed a high-fat diet, 5 days of liraglutide administration effectively improved body weight, glucose tolerance, and lipid profiles to levels that were similar to WT mice.

**Conclusion:** Loss of SHP expression protected against high fatty liver and dyslipidemia through decreased expression of PPARγ mRNA and increased expression of Cyp7A1 mRNA. GLP-1 analogs were effective in metabolic syndrome observed in both WT and SHP-/- mice fed a high-fat diet. Combination therapy of SHP inhibitors and GLP-1 analogs may be a potential treatment strategy for metabolic syndrome.

## 641

### Enhanced PPARγ and NF-κB activity contributes to impaired insulin sensitivity and ectopic fat deposition in SIRT1<sup>+/-</sup> mice

F. Xu<sup>1</sup>, Z. Gao<sup>2</sup>, J. Zhang<sup>2</sup>, J. Ye<sup>2</sup>, J. Weng<sup>1</sup>

<sup>1</sup>Endocrinology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China, <sup>2</sup>Antioxidant and Gene Regulation Laboratory, Pennington Biomedical Research Center, Baton Rouge, USA.

**Background and aims:** SIRT1 is a class III histone deacetylase whose activity is activated in the body by fasting or calorie restriction. It was reported that SIRT1 promoted lipid mobilization by inhibition of ligand-dependent PPARγ activity in adipocytes. SIRT1 was also reported to inhibit inflammation by suppressing the transcriptional activity of NF-κB. However, those activities were observed in cellular models. It remains unclear how these SIRT1 activities are integrated in vivo in the regulation of lipid metabolism. To address this issue, we examined metabolic phenotype of the SIRT1<sup>+/-</sup> mice.

**Materials and methods:** The SIRT1 heterozygous KO (SIRT1<sup>+/-</sup>) mice and wild type (WT) littermates with C57BL/6 background were used as subjects in the study. Systemic evaluations were as follows: Fat mass and body composition was measured using quantitative nuclear magnetic resonance (NMR). Blood glucose was measured every 2–4 week. Insulin was detected in the plasma both on basal level and after diet intervention. Intraperitoneal glucose tolerance test (IPGTT) and insulin tolerance test (IPITT) were performed after 12 weeks diet intervention. Liver and fat tissues (epididymal and retroperitoneal fat pads) were collected and weighed, and histology study was carried out with liver and fat tissue such as HE staining and immunohistochemistry. Quantitative real-time PCR and western blotting were used to detect mRNA and protein expression, respectively.

**Results:** Compared to the wild type littermates, the SIRT1<sup>+/-</sup> mice had more body fat on chow diet. Their lean body mass, physical activity and food intake were not altered. The increased adiposity did not induce adipose tissue expansion as the mass of epididymal fat, retroperitoneal fat, and inguinal fat pads was not increased in the SIRT1<sup>+/-</sup> mice, however, liver weight and liver/body ratio was elevated, suggesting an ectopic fat deposition in the liver. IPGTT and IPITT results showed impaired glucose tolerance and insulin sensitivity in the SIRT1<sup>+/-</sup> mice, respectively. The adipose tissue exhibited an elevation in inflammation as indicated by cytokine expression and macrophage infiltration, suggesting an increase in the NF-κB activity. However, the adipose tissue structure was not altered in adipocyte size, cell density, and the extracellular matrix. In vitro, adipogenesis of SIRT1<sup>+/-</sup> preadipocyte was enhanced as determined by staining with DAPI and BODIPY493/503. Hepatic steatosis was enhanced as indicated by liver/body ratio, liver size, and lipid content, which were all significantly increased in the SIRT1<sup>+/-</sup> mice. Protein expression of liver suggesting enhanced PPARγ and NF-κB activity.

**Conclusion:** In the SIRT1<sup>+/-</sup> mice, the reduced SIRT1 activity leads to impaired insulin sensitivity, but failed to induce adipose tissue expansion. The data suggests that the enhanced NF-κB activity may promote inflammation in adipose tissue and inhibit the tissue expansion. The elevated PPARγ and NF-κB activity in hepatocytes together with the adipose tissue dysfunction may promote the hepatic steatosis. Therefore, the enhanced NF-κB and

PPARγ activity may be the underlying mechanism for the impaired insulin sensitivity and ectopic lipid deposition in the SIRT1<sup>+/-</sup> mice.

### Metabolic effects of dietary n-3 fatty acids supplied as phospholipids reflect down-regulation of biosynthetic pathways in the liver of mice fed a high-fat diet

J. Roubalova, M. Rossmeisl, J. Kopecky;

Adipose Tissue Biology, Institute of Physiology Academy of Sciences of the Czech Republic v.v.i., Prague, Czech Republic.

**Background and aims:** We have shown previously that a combination treatment using dietary n-3 polyunsaturated fatty acids (n-3 PUFA) in the form of triglycerides and thiazolidinedione (TZD) antidiabetic drugs could efficiently prevent or reverse obesity in mice fed obesogenic high-fat diet, while ameliorating insulin resistance primarily through the effect on skeletal muscle. Recent animal experiments as well as studies in human subjects have also suggested that n-3 PUFA as phospholipids might be superior to triglycerides, especially with regard to the effect on hepatic steatosis. Therefore, in this study, we investigated how n-3 PUFA as phospholipids, either alone or in combination with TZD, affect hepatic steatosis as well as lipid and glucose metabolism.

**Materials and methods:** Adult male C57BL/6N mice were fed for 7 weeks a corn oil-based high-fat diet (cHF; lipids ~35% wt/wt) or various cHF-based treatments: (i) PC, cHF with n-3 PUFA as phosphatidylcholine-rich concentrate replacing ~7 % of dietary lipids; ii) R, cHF with 10 mg rosiglitazone/kg diet; iii) PC+R. Chow-fed mice served as controls for the effect of cHF feeding. Glucose tolerance, markers of glucose and lipid homeostasis, hepatic steatosis, and hepatic gene expression were assessed.

**Results:** Both PC and PC+R but not R prevented weight gain (cHF, 15.9 ± 1.2; PC, 4.9 ± 1.1; R, 12.1 ± 1.9; PC+R, 2.0 ± 0.9 g; p<0.05), while all treatments markedly reduced the weight of abdominal fat depot (cHF, 2.67 ± 0.14; PC, 1.19 ± 0.17; R, 1.86 ± 0.25; PC+R, 0.71 ± 0.12 g; p<0.05). All treatments also reduced plasma levels of triacylglycerols and NEFA, however total cholesterol was lower only in the PC and PC+R groups (cHF, 4.3 ± 0.1; PC, 3.4 ± 0.3; R, 4.0 ± 0.3; PC+R, 3.3 ± 0.2 mmol/l; p<0.05). Both PC and PC+R also improved glucose tolerance (AUC for glucose; cHF, 1.30 ± 0.11; PC, 0.89 ± 0.06; R, 1.09 ± 0.11; PC+R, 0.61 ± 0.13 mol\*180 min; p<0.05). While R tended to increase hepatic lipids, both PC and PC+R treatments completely prevented the development of fatty liver (cHF, 81 ± 3; PC, 40 ± 4; R, 117 ± 25; PC+R, 40 ± 3 mg/g tissue; p<0.05). Furthermore, screening of hepatic gene expression by microarrays showed a complex and significant down-regulation of many biosynthetic pathways including lipogenesis as well as cholesterol and bile acid synthesis in the PC group. Conversely, fatty acid oxidation was stimulated, and the PC+R combination further potentiated this effect. The expression of key regulatory genes within each pathway was verified by quantitative real-time RT-PCR and yielded a perfect conformity with microarrays.

**Conclusion:** Dietary n-3 PUFA as phospholipids efficiently ameliorated obesity-associated metabolic defects such as dyslipidemia and glucose intolerance, while completely preventing the development of fatty liver. The latter effect was associated with a complex inhibition of biosynthetic pathways in the liver. Prevention of weight gain and improvement in glucose tolerance were further potentiated when PC was combined with a low dose of TZD, suggesting its potential use in clinical settings.

### Itch, an E3 ubiquitin ligase, is a new target for nonalcoholic steatohepatitis

A. Marino, M. Cardellini, R. Menghini, F. Davato, A. Peschiaroli, P. Sbraccia, P. Gentile, G. Melino, R. Lauro, M. Federici;

Medical School, University Tor Vergata, Rome, Italy.

**Background and aims:** Nonalcoholic steatohepatitis (NASH) is a complication of nonalcoholic fatty liver disease (NAFLD) occurring in 10–20% of patients affected. The molecular mechanisms underlying the transition from NAFLD to NASH are unclear. We performed a microarray analysis to compare human livers from severe obese subjects with normal glucose tolerance

and simple hepatic steatosis (NGT/SS) to patients with severe obesity, diabetes and steatohepatitis (DM2/SH) to identify potential targets involved in the transition from NAFLD to NASH. Among the down regulated genes in DM2/SH we focused on *itch*/AIP4. This gene encode for an E3 ubiquitin ligase whose role is to target different proteins, involved in JNK and NF $\kappa$ B pathway, for proteasomal degradation. *Itch* is also known to be involved in the development of different types of cancers.

**Materials and methods:** Microarrays studies were performed comparing 3 NGT/SS to 3 DM2/SH; results were validated in a cohort of 25 subjects with severe obesity and different degrees of hepatic steatosis and inflammation. To investigate the potential role of *itch* in development of steatohepatitis we used *in vitro* and *in vivo* model of fatty liver disease. Murine hepatocytes cells were cultured in presence or not of FFAs (palmitic acid 0.5mM, oleic acid 1mM) for 6 h; expression of *itch* and its targets was evaluated by real-time PCR and western blot. WT mice fed standard chow and high fat diet (HFD, 60% cal from fat) for 16 weeks were subjected to *itch* liver expression analysis by real-time PCR and western blot. We also studied the expression of *itch* in mice treated with HFD and the hepatic procarcinogen diethylnitrosamine (DEN) as an inducer of hepatocellular carcinoma (HCC).

**Results:** In subjects with DM2/SH we confirmed significantly reduced *itch* expression in liver biopsies by real-time PCR and western blot ( $p<0.05$ ). Immunohistochemical analysis of liver biopsies showed reduced *itch* expression in cytoplasm and nuclei of hepatocytes in steatotic areas. In FFAs stimulated hepatocytes compared with untreated cells, we observed a significant reduced mRNA expression and protein levels of *itch* ( $p<0.01$  and  $p<0.05$ , respectively) and an increase in *itch* targets RIP1 and c-FLIP<sub>L</sub> ( $p<0.05$ ). We questioned if *itch* expression could be reduced in animal model of diet induced obesity and hepatic steatosis. Total liver mRNA and protein analysis showed decreased *itch* expression in liver but not adipose tissue from WT mice fed HFD for 16 weeks compared to control mice fed normal diet (ND) ( $p<0.001$ ). We confirmed that deficit in *itch* expression was predominant in hepatocytes cells by gene expression analysis comparing purified hepatocytes to non parenchymal cells isolated from HFD and ND mice liver tissues. Similarly to *in vitro* studies, levels of *itch* targets were increased ( $p<0.05$ ). In a model of obesity-related HCC we found that *itch* expression was reduced in tumor areas compared to tumor free areas ( $p<0.05$ ). Given the effect of FFA and HFD on *itch* expression and function, we studied whether *itch* KO mice are more sensitive to HFD.

**Conclusion:** Our results suggest that *itch* down regulation occur during steatohepatitis development and can influence the course of disease. Further studies must be performed to understand if *itch* could be considered a predictor of poor prognosis and eventually used as prognostic marker in nonalcoholic fatty liver disease.

## PS 045 Novel players in the development of insulin resistance

### Differential effects of antibiotics on intestinal microbiota composition and insulin resistance in obese humans; a randomised controlled trial

A. Vrieze<sup>1</sup>, C. Out<sup>2</sup>, L. Jonker<sup>1</sup>, F. Holleman<sup>1</sup>, G.M. Dallinga-Thie<sup>1</sup>, M.T. Ackermans<sup>3</sup>, M.J. Serlie<sup>3</sup>, F. Knop<sup>4</sup>, J.J. Holst<sup>4</sup>, H.G.H. Heilig<sup>5</sup>, W.M. de Vos<sup>5,6</sup>, A.K. Groen<sup>3</sup>, E.G. Zoetendal<sup>5</sup>, J.B.L. Hoekstra<sup>1</sup>, M. Nieuwdorp<sup>1</sup>;

<sup>1</sup>Department of Internal & Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands, <sup>2</sup>Department of Center for Liver, Digestive, and Metabolic Diseases, University Medical Center Groningen, Netherlands, <sup>3</sup>Department of Endocrinology and Metabolism, Academic Medical Center, Amsterdam, Netherlands, <sup>4</sup>Department of Internal Medicine, Gentofte Hospital, Hellerup, Denmark, <sup>5</sup>Laboratory of Microbiology, Wageningen University, Netherlands, <sup>6</sup>Department of Basic Veterinary Medicine, University of Helsinki, Finland.

**Background and aims:** Recent data in animal models reveal that obesity is associated with substantial changes in composition and metabolic function of intestinal microbiota. Moreover, intestinal microbiota modulation with antibiotics against gram positive bacteria alters oral glucose tolerance in mice. We hypothesized that short term oral antibiotic treatment affects faecal microbiota composition and subsequent glucose metabolism in obese male subjects with metabolic syndrome.

**Materials and methods:** In this randomised controlled trial, 20 male subjects with metabolic syndrome (no medication use) were randomised to either 7 days amoxicillin 500 mg tid ( $n=10$ ) or 7 days vancomycin 500 mg tid ( $n=10$ ). We studied insulin resistance (by hyperinsulinaemic normoglycaemic clamp with stable isotopes) and intestinal microbiota composition before and after these antibiotics.

**Results:** We found a significant decrease of peripheral insulin sensitivity in the vancomycin treatment group (median Rd from 31.9 to 30.7  $\mu\text{mol/kg/min}$ ,  $p<0.05$ , Figure 1), whereas amoxicillin did not have a significant effect (median Rd from 26.7 to 25.8  $\mu\text{mol/kg/min}$ ,  $p=\text{ns}$ ). There was no change in hepatic insulin sensitivity in any of the groups. An increase in fasting glucagon levels was seen upon vancomycin treatment (median glucagon from 80 to 95 ng/L,  $p<0.01$ ), whereas amoxicillin had no effect (median glucagon from 72 to 67 ng/L,  $p=\text{ns}$ ).

**Conclusion:** Reducing gram positive gut microbiota by vancomycin affects peripheral insulin resistance and glucagon secretion in obese subjects with metabolic syndrome, underscoring the potential role of intestinal microbiota in the regulation of glucose metabolism. Impact of antibiotic treatment on the intestinal microbiota composition will be presented and discussed.

**Figure 1.** Individual change in peripheral insulin sensitivity after vancomycin

## 645

**Obesity alters clock gene expression in human visceral adipose tissue**E. Gonzalez-Ruano<sup>1,2</sup>, E. Vieira<sup>1,2</sup>, F.A. Hanzu<sup>3</sup>, A. Jimenez<sup>4</sup>, Y. Esteban<sup>1,2</sup>, R. Gomis<sup>1,2</sup>;<sup>1</sup>CIBERDEM, <sup>2</sup>IDIBAPS, <sup>3</sup>Endocrinology and Nutrition Unit Hospital Clinic, <sup>4</sup>Endocrinology and Nutrition Unit, Hospital Clinic, Barcelona, Spain.

**Background and aims:** Disturbances in the circadian rhythms have emerged as one of the possible causes in the development of obesity and type 2 diabetes. Indeed, changes in the sleep patterns because of night shift works are related with higher risk to develop obesity and type 2 diabetes, highlighting the importance of circadian clock in the metabolic and energetic regulation. The central pacemaker is located in the suprachiasmatic nuclei in the hypothalamus it is controlled by a transcriptional/translational feedback loops involving a set of clock genes. Recently, it has been shown that the human adipose tissue has a fully functional circadian clock gene mechanism whose expression is associated with different components of metabolic syndrome. Thus, the aim of the study was to identify the main clock genes that might be disrupted in visceral adipose tissue from lean and obese subjects.

**Materials and methods:** Visceral adipose tissue was obtained from lean and obese women patients (n=8; age= 47.6± 4.2 in obese vs 46.3±7.2 in lean) that were subjected to bariatric surgeries at our hospital. The day before the patients were synchronized at having lunch and dinner and the AT biopsies were taken between the 11.00 and 13.00. The mRNA expression of clock genes was performed by real time PCR. Total RNA was extracted using RNeasy lipid mini kit (Qiagen). Reverse transcription was performed with random hexamers as primers and Superscript III (Invitrogen). Quantitative real-time PCR was carried out in LightCycler 480 (Roche) using MESAGreen (Eurogentec) and specific primers for each gene analyzed. Expression analysis was done with 2-ΔΔCt method. For statistical analysis paired t-Student test was performed using Graphpad prism 5.0 software

**Results:** The baseline clinical and metabolic characteristics shows differences in insulin resistance estimated by HOMA-IR (5.8 ± 1.8 vs < 2.93 ), plasma insulin (202.8 ± 78.5 vs 15.3-98.6 pmol/L) and adiponectin (12.8 ± 3.5 vs 16.7-23.3 ug/ml ) between obese and lean subjects, found no differences in other clinical variables analyzed. First, we compared the expression levels of main clock genes, Rora, Rev-erba, Bmal1, Cry1, Cry2, Per1 and Per2 with the expression levels of the gene Clock within the lean and the obese group. In the lean group, the mRNA expression of clock genes was very low with the highest expression detected in Per1 mRNA levels. In the obese group, clock and Rev-erbalpha had the same gene expression levels whereas Per1 had a 6 times higher expression levels and Cry2 had 3 times higher expression levels than clock. When we compared lean versus obese subjects, the mRNA levels of Cry2 were increased in obese patients compared to lean subjects as well as there is a strong tendency for the upregulation of Clock in obese patients (p=0.053) versus lean subjects. Interestingly, the nuclear receptor Rev-erba which was suggested to link circadian rhythms and metabolism had 3 times higher expression levels of in obese patients compared to lean subjects.

**Conclusion:** Our results show that obesity alters the expression pattern of Cry2, Clock and Rev-erbalpha in human visceral adipose tissue. The clock gene specific changes in human visceral adipose tissue can help to develop new strategies and therapies for the treatment of obesity.

## 646

**TNF-related apoptosis-inducing ligand significantly attenuates metabolic abnormalities in high fat fed mice reducing adiposity and systemic inflammation**S. Bernardi<sup>1</sup>, G. Zauli<sup>2</sup>, C. Tikellis<sup>3</sup>, C. Bruce<sup>3</sup>, M. Febbraio<sup>3</sup>, R. Candido<sup>4</sup>, B. Fabris<sup>1</sup>, P. Secchiero<sup>2</sup>, M.E. Cooper<sup>3</sup>, M.C. Thomas<sup>3</sup>;<sup>1</sup>University of Trieste, Italy, <sup>2</sup>University of Ferrara, Italy, <sup>3</sup>Baker IDI, Melbourne, Australia, <sup>4</sup>Centro Diabetologico, Trieste, Italy.

**Background and aims:** Tumor necrosis factor (TNF)-related apoptosis inducing ligand (TRAIL) has recently been shown to ameliorate the natural history of diabetes mellitus (DM). It has not been determined yet whether systemic TRAIL delivery would prevent the metabolic abnormalities due to a high fat diet (HFD).

**Materials and methods:** For this purpose 27 male mice C57bl6 aged 8 weeks were randomly allocated to standard diet, HFD or HFD + TRAIL for 12 weeks. TRAIL was delivered weekly by intra-peritoneal injection. Body composition was evaluated; indirect calorimetry studies, glucose tolerance test

(GTT) and insulin tolerance tests (ITT) were performed. Pro-inflammatory cytokines together with adipose tissue gene expression and apoptosis were measured.

**Results:** TRAIL treatment reduced significantly the increased adiposity associated with a HFD. Moreover, it reduced significantly hyperglycaemia and hyperinsulinemia during a GTT and it improved significantly the peripheral response to insulin. TRAIL reversed the changes in substrate utilization induced by HFD and ameliorated skeletal muscle free fatty acid oxidation rate. This was associated with a significant reduction of pro-inflammatory cytokines together with a modulation of adipose tissue gene expression and apoptosis.

**Conclusion:** This data sheds light on the possibility of fat regulation by TRAIL and opens new therapeutic possibilities against obesity, systemic inflammation and type 2 DM.

## 647

**The role of glucocorticoids in glucose intolerance development in MIF-deficient mice**

I. Stojanovic, I. Nikolic, T. Saksida, M. Vujicic, S. Stosic-Grujicic; Immunology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Serbia.

**Background and aims:** Macrophage migration inhibitory factor (MIF) is a cytokine with versatile functions including promotion of inflammation, regulation of glucose metabolism and inhibition of immunosuppressive effects of glucocorticoids. It has been established that MIF deficiency provokes beta cell dysfunction, development of glucose intolerance and obesity in mice. Since elevated glucocorticoids are implicated in diabetes development, the aim of this study was to explore the relationship between MIF and the level of glucocorticoids in disease development.

**Materials and methods:** MIF-deficient mice (MIF-KO) and their wild type (WT) counterparts C57BL/6 were first tested for the concentration of corticosterone in the serum by ELISA, for the expression of glucocorticoid receptor (GR) in spleen cells and pancreatic lymph node cells by flow cytometry, and for the expression of GR in pancreatic islets by Western blot analysis. Next, mice were treated either with a GR inhibitor mifepristone (20 mg/kg bw) or with sesame oil and DMSO in the same concentration (diluent) for 7 days. Intraperitoneal glucose tolerance test was performed before and after the end of the treatment, while blood glycemia was measured weekly during the next five weeks. Insulin secretion from *in vitro* cultured pancreatic islets was determined by ELISA. Statistical significance between groups was calculated by ANOVA *t* test.

**Results:** Serum corticosterone was elevated in MIF-KO animals compared to WT mice, while the expression of glucocorticoid receptor in lymphoid tissues was similar to the one seen in C57BL/6 mice. Pancreatic islets from MIF-KO seemed to have lower protein expression of GR. After *in vivo* GR inhibition glucose tolerance in MIF-KO mice significantly improved compared to diluent-treated mice. Although blood glucose level in mifepristone-treated MIF-KO mice was lower immediately after the end of the treatment, it rose over time and after 4 weeks returned to the level observed in diluent-treated mice. Mifepristone did not improve already impaired function of beta cells from MIF-KO mice.

**Conclusion:** Elevated glucocorticoids in MIF-KO mice are probably a result of the absence of negative feedback mechanisms mediated by MIF. This excess of glucocorticoids could partly account for the observed development of glucose intolerance in MIF-KO mice since GR inhibition transiently improved control of glycemia. These results give new insight in the delicate balance between MIF and glucocorticoids in diabetes development.

**Deficiency of tetrahydrobiopterin induces insulin resistance and progression of diabetes**

A. Abudukadier<sup>1</sup>, Y. Fujita<sup>1</sup>, A. Obara<sup>1</sup>, A. Ohashi<sup>2</sup>, T. Fukushima<sup>1</sup>, Y. Sato<sup>1</sup>, Y. Nakamura<sup>1</sup>, S. Yamane<sup>1</sup>, M. Ogura<sup>1</sup>, M. Hosokawa<sup>1</sup>, H. Hasegawa<sup>2</sup>, N. Inagaki<sup>1</sup>;

<sup>1</sup>Department of Diabetes and Clinical Nutrition, Graduate School of Medicine, Kyoto University, <sup>2</sup>Department of Functional Morphology, Nihon University School of Medicine, Tokyo, Japan.

**Background and aims:** Endothelial nitric oxide synthase (eNOS) dysfunction occurs in conditions of diabetes and insulin resistance. In addition, eNOS dysfunction is known to be involved in deteriorating insulin sensitivity and glucose metabolism. These findings suggest that the factors which regulate eNOS activity also play an important role in regulating insulin sensitivity and glucose metabolism. Tetrahydrobiopterin (BH4) is an essential co-factor of eNOS, and is synthesized mainly in liver. Our previous study showed that liver BH4 content was decreased in conditions of diabetes and that its supplementation suppressed gluconeogenesis in liver and lowered blood glucose levels eNOS-dependently. The aim of this study was to investigate the effect of BH4 deficiency on progression of diabetes and insulin resistance using the mouse model of BH4 deficiency.

**Materials and methods:** We used hph-1 mice and control mice of the same background (C57BL/6×CBA mice). The hph-1 mouse exhibits a genetic 90% deficiency in GTP-cyclohydrolase I (GTPCH I), a rate-limiting enzyme in BH4 syntheses, and a marked reduction in BH4 levels. Blood glucose levels and plasma insulin levels of these mice were measured. Intraperitoneal glucose tolerance test (IPGTT), insulin tolerance test (ITT), and pyruvate tolerance test (PTT) were performed. Saline with or without 10mg/kg BH4 was administered twice daily intraperitoneally for 7 consecutive days and blood glucose levels were measured. Protein expressions of AMP activated protein kinase (AMPK)  $\alpha$ , phospho-AMPK $\alpha$ , AKT, and phospho-AKT were analyzed by western blotting.

**Results:** Six-week old hph-1 mice fed normal chow exhibited overt diabetes: fasting blood glucose levels (hph-1,  $72.1 \pm 2.8$  mg/dl; control,  $48.1 \pm 2.3$  mg/dl;  $p < 0.001$ ) and fed blood glucose levels (hph-1,  $181.5 \pm 2.6$  mg/dl; control,  $147.3 \pm 7.5$  mg/dl;  $p < 0.001$ ). Body weight of the two groups was not statistically different. The hph-1 mice had higher fasting plasma insulin levels (hph-1,  $284.7 \pm 82.4$ ; control,  $97.7 \pm 12.0$ ;  $p < 0.05$ ) and higher fed plasma insulin levels (hph-1,  $900.2 \pm 89.1$  pg/ml; control,  $604.7 \pm 70.7$  pg/ml;  $p < 0.05$ ). In IPGTT, despite the higher plasma insulin levels compared to those in control mice, hph-1 mice exhibited impaired glucose tolerance (expressed as area under the curve (AUC) from 0 to 120 min, hph-1,  $39.1 \times 10^3$  mg/dl×min; control,  $24.7 \times 10^3$  mg/dl×min;  $p < 0.001$ ). ITT data showed that the hph-1 mice had insulin resistance. PTT data showed that hph-1 mice had higher liver glucose production than control mice, and that activation of AMPK was decreased in liver tissues of hph-1 mice. To assess the correlation between BH4 content and glucose metabolism, hph-1 mice were treated with BH4. BH4 treatment significantly lowered blood glucose levels. AMPK and AKT were activated by administration of BH4 in liver tissues of hph-1 mice.

**Conclusion:** These findings suggest that endogenous BH4 regulates systemic glucose metabolism and that its deficiency can induce insulin resistance and progression of diabetes. BH4 and its rate-limiting enzyme GTPCH I are possible targets for treatment and prevention of diabetes.

## 649

**Response of different mouse strains to a high fat diet: BALB/c mice are resistant to diet-induced obesity and insulin resistance**

M.K. Montgomery, N.J. Hallahan, G.J. Cooney, N. Turner; Diabetes & Obesity Research Program, Garvan Institute of Medical Research, Darlinghurst, Australia.

**Background and aims:** Transgenic and knockout mice are major research models used to investigate the aetiology of obesity and type 2 diabetes, with many proposed therapeutic target proteins identified using this approach. However, genetically manipulated mice are produced on a range of different genetic backgrounds and there is only limited information on the inherent propensity of different mouse strains to develop metabolic disease. To investigate strain-dependent differences in the susceptibility of mice to diet-induced obesity and insulin resistance, we have carried out an extensive comparison of the response to a high fat diet (HFD) of five commonly used mouse strains (DBA/2, 129X1/SvJ, BALB/c, C57BL/6 and FVB/N).

**Materials and methods:** Mice were fed either a standard low-fat laboratory diet (LFD; 8% calories from fat) or a HFD (45% calories primarily from lard) for 8 weeks ( $n=8$  for each strain and diet). At the end of the feeding period, body composition was determined using dual-emission X-ray absorptiometry and glucose tolerance was measured during an intraperitoneal glucose tolerance test. Tissues were collected for subsequent analysis.

**Results:** Body weight was higher in three out of five mouse strains (DBA/2, 129X1/SvJ and FVB/N) in response to a HFD, while whole-body fat mass was significantly increased (+40–90%,  $P < 0.001$ ) by fat-feeding in all strains. Glucose tolerance was significantly impaired by the HFD in all strains except BALB/c, where the HFD animals displayed similar glucose tolerance to LFD counterparts. Consistent with these findings, insulin sensitivity (as indicated by HOMA-IR index) was maintained at the level of LFD controls in fat-fed BALB/c mice, but was significantly reduced in all other mouse strains. Tissue triglyceride (TAG) levels were assessed to determine if differential accumulation of lipid in non-adipose tissue may be associated with the disparate effects of the HFD on insulin action. The DBA/2, 129X1/SvJ, C57BL/6 and FVB/N mice all displayed significant increases in muscle and liver TAG in response to the HFD (+70–380%,  $P < 0.001$ ). Intriguingly, BALB/c mice did not accumulate excess liver triglycerides, despite a similar increase in lipid deposition in skeletal muscle compared to other strains. In the liver, there was minimal variation in markers of mitochondrial oxidative capacity across the strains. Despite the lack of TAG accumulation and the maintenance of insulin sensitivity in response to HFD, BALB/c mice were the only strain that displayed an increase in lipid oxidative damage in liver (both lipid hydroperoxide and TBARS).

**Conclusion:** This detailed mouse strain comparison highlights the importance of genetic background in determining the metabolic response to HFD. In addition, we showed that impaired glucose tolerance correlates with lipid accumulation in the liver, but not in skeletal muscle. Furthermore, our findings suggest that accumulation of neutral triglycerides might prevent the formation of other harmful lipid species that cause lipoxidative damage.

**Susceptibility genes for type 2 diabetes and related phenotypes cluster on mouse chromosome 14**

N. Babaya<sup>1</sup>, S. Noso<sup>1</sup>, Y. Hiromine<sup>1</sup>, H. Ueda<sup>2</sup>, H. Ikegami<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Metabolism and Diabetes, Kinki University Faculty of Medicine, Osaka-sayama, Japan, <sup>2</sup>Department of Molecular Endocrinology, Osaka University Graduate School of Medicine, Suita, Japan.

**Background and aims:** We mapped a quantitative trait locus on chromosome (Chr) 14 (*Nidd2n*) affecting diabetes-related phenotypes in crosses of NSY mice, an animal model of spontaneous type 2 diabetes, with control C3H mice. Recently, we constructed a consomic strain, C3H-14<sup>NSY</sup>, in which NSY-derived whole Chr14 was introgressed onto control C3H background genes, and clarified that the Chr14 harbor major susceptibility gene(s) for type 2 diabetes. The aim of this study is to localize the region and to clarify the function of susceptibility genes for type 2 diabetes on Chr14.

**Materials and methods:** We constructed two novel congenic strains homozygous for different segments of NSY-Chr14 on the control C3H background: R1 strain possesses proximal and middle segment of NSY-Chr14 and R2 strain possesses most proximal segment of NSY-Chr14. Various kinds of diabetes-related phenotypes of congenic strains have been monitored longitudinally in comparison with consomic C3H-14<sup>NSY</sup> and parental NSY and C3H strains.

**Results:** Congenic R1 and R2 mice showed significantly higher blood glucose level than C3H mice ( $p < 0.01$ ). Hyperglycaemia in R1 and R2 mice, however, were not as severe as in consomic C3H-14<sup>NSY</sup> mice ( $p < 0.05$ ). Insulin resistance observed in C3H-14<sup>NSY</sup> mice was retained in both R1 and R2 mice. C3H-14<sup>NSY</sup>, R1 and R2 mice showed severe adiposity than C3H mice ( $p < 0.01$ ). R2 showed significantly higher body weight than C3H mice ( $p < 0.001$ ), in contrast to no significant increase in body weight in R1 and C3H-14<sup>NSY</sup> mice. Leptin level was significantly higher in R1, R2 and C3H-14<sup>NSY</sup> as well as in NSY mice than in C3H mice ( $p < 0.01$  for all). No significant difference was observed in leptin level between R1 and C3H-14<sup>NSY</sup> mice. Leptin level in R2 mice, however, was significantly higher than in C3H-14<sup>NSY</sup> mice ( $p < 0.001$ ), and similar to NSY mice, despite the heavier body weight and fat-pad weight in NSY mice. Serum leptin levels were significantly correlated with abdominal fat pads in NSY ( $r=0.75$ ,  $p < 0.05$ ) and congenic, consomic and parental C3H mice ( $r=0.78$ ,  $p < 0.001$ ). Serum adiponectin level was significantly higher in NSY than in C3H mice ( $p < 0.05$ ), but was significantly lower in C3H-14<sup>NSY</sup>, R1 and R2 than

in C3H mice ( $p < 0.001$ ). Serum adiponectin levels were significantly correlated with abdominal fat pads in congenic, consomic and parental C3H mice ( $r = -0.48$ ,  $p < 0.01$ ), but not in NSY mice.

**Conclusion:** These data provide direct evidence that proximal region of mouse Chr14 harbor a gene or genes for insulin resistance and adiposity/obesity, which interact epistatically with the non-proximal region of Chr14. Serum levels of adiponectin, but not leptin, were dysregulated in NSY mice, which is controlled by a gene or genes outside of Chr 14.

### Insulin-resistance and low-grade inflammation: the role of low and chronic doses of bisphenol-a on adipocyte function

R. Valentino<sup>1</sup>, V. D'Esposito<sup>2</sup>, F. Passaretti<sup>2,3</sup>, D. Liguoro<sup>1</sup>, A. Rainone<sup>2</sup>, P. Formisano<sup>2</sup>, F. Beguinot<sup>2</sup>;

<sup>1</sup>IEOS-CNR, Naples, <sup>2</sup>DBPCM, University of Naples "Federico II", Naples, Italy, <sup>3</sup>Department of Pharmaceutical Science, University of Salerno, Italy.

**Background and aims:** Bisphenol-A (BPA) is a lipophilic compound, main component of plastic and one of the highest-volume chemicals in commerce. At very low doses displays strong estrogen-like activities, altering several metabolic, but also inflammatory functions. It is detectable at nanomolar levels in human serum and urine worldwide and is detected in the packaging of food, in beverage containers and in material commonly used in dentistry. Considering the BPA bio-accumulation in adipose tissue, the involvement of this compound in obesity, insulin resistance, metabolic syndrome and type II diabetes, all challenging and growing health problems, is suggestive. The aim of the current work is to investigate the effect of low and chronic BPA doses on adipocyte function, in term of insulin signaling and adipokine production. **Materials and methods:** Preadipocytes (fibro3T3-L1) and differentiated (adipo3T3-L1) cells have been cultured for 24-48 and 72 h in presence of 1 nM BPA, and acutely stimulated (10 min) with 100 nM insulin. Fibro3T3-L1 cells have been also cultured continuously in presence of 1 nM BPA for two weeks and during adipogenesis (further ten days). AKT, ERK, STAT and JNK activation pathways were analyzed by Western blot with phospho-specific antibodies. Moreover, different adipokines were assayed in conditioned media using BIOPLEX multipanel assay.

**Results:** After 24-48 and 72h incubation with 1 nM BPA, insulin-stimulated AKT and ERK phosphorylation was down-regulated with no change of protein abundance. These differences were more marked when fibro3T3-L1 and adipo3T3-L1 were incubated chronically with 1 nM BPA. Interestingly, the IL-6 and MIP-1α levels in conditioned media from adipo3T3-L1 were higher in presence of BPA. Moreover, STAT and JNK phosphorylation was also increased, likely as the results of stimulation with inflammatory cytokines.

**Conclusion:** Chronic BPA bio-accumulation in adipose tissue, at very low concentrations, interferes with insulin signaling and adipose cell activity, with possible development of low-grade inflammation. BPA disrupts important cellular functions in adipocytes, such as AKT and ERK activities, leading to insulin resistance. Our hypothesis is that BPA, possibly via estrogen and/or Toll-like receptors, is able to activate pathways leading to low grade inflam-

mation and insulin-resistance, altering the main adipose tissue functions. Further experiments are required to verify the interference of BPA low and chronic doses on adipogenesis and the impact of BPA on insulin action in human insulin-dependent tissues.

### Palmitate-induced transitory activation of mTORC2/AKT pathway leads to ER stress and cell death independently of mTORC1

T.M. de Araújo<sup>1</sup>, J.A. Faria<sup>1</sup>, A.P. Kinote<sup>1</sup>, A.L. Barbosa<sup>1</sup>, L.A. Velloso<sup>2</sup>, G.F. Anhe<sup>1</sup>;

<sup>1</sup>Pharmacology, <sup>2</sup>Internal Medicine, University of Campinas, Brazil.

**Background and aims:** AKT is a serine/threonine protein kinase that is essential for regulating cell growth, proliferation, survival and the interaction with environmental stimuli. Classically, AKT is fully activated by phosphoinositide-dependent kinase 1 (PDK1) and mammalian Target of Rapamycin (mTOR) complex 2, leading to inhibition of apoptosis. Alternatively, transitory AKT activation was demonstrated to cause cell death through yet not described mechanisms. Excess of free-fatty acids (FFA) are known to contribute to steatosis and cell death in hepatocytes due to activation of ER stress-related pathways. ER stress triggers the Unfolded Protein Response (UPR) that is comprised by three independent branches; the PKR-like ER kinase (PERK), the activating transcription factor (ATF)-6 and serine/threonine-protein kinase/endoribonuclease Ire1. The aim of this study is to demonstrate if short-term AKT activation by palmitate is linked to ER stress and apoptosis in HepG2 cells.

**Materials and methods:** HepG2 cells were treated with palmitate (0,5 mmol/l) pre-conjugated with albumin, rapamycin (500 nmol/l) and/or wortmannin (1 nmol/l). Cells were also transfected with siRNA targeted to Raptor or a siRNA targeted to Rictor. A scrambled siRNA was used as control. mTORC2/AKT pathway and UPR were assessed by Western blotting. Cell death was assessed by DNA fragmentation.

**Results:** Palmitate-induced apoptosis was maximal after 12h of treatment. CHOP, a marker of ER-stress-dependent apoptosis was also modulated by palmitate and peaked 12h after beginning of treatment but was already enhanced as early as 6h after exposition to palmitate. Processed ATF6 was up-regulated 3h after palmitate exposition and these levels were sustained for 12h after treatment with FFA. Palmitate also activated PERK and increased ATF4 expression (respectively after 6 and 12h of treatment). By inhibiting mTORC1/2 with rapamycin we observed a suppression of palmitate-induced UPR activation and apoptosis. In contrast, Raptor knockdown had no effects over palmitate-induced apoptosis. Rictor knockdown, instead, reduced palmitate-induced apoptosis. Similarly, pre-treatment of HepG2 cells with wortmannin reduced palmitate-induced apoptosis.

**Conclusion:** Our results demonstrated that palmitate induces a short-term and transitory AKT activation that leads to long term activation of UPR and apoptosis. This response is likely to be triggered by mTORC2 activation rather than mTORC1.

### Effects of hyperglycaemia on the regulation and expression of the ApoE, Igfbp1 and Foxo1 genes in HepG2 cells

F.G. Ghiraldini<sup>1</sup>, N. Gilbert<sup>2</sup>, M.L.S. Mello<sup>1</sup>;

<sup>1</sup>Structural and Physiological Biology, UNICAMP, Campinas, Brazil,

<sup>2</sup>Edinburgh Cancer Research Center, Edinburgh, UK.

**Background and aims:** Hyperglycemia caused by diabetes mellitus (DM) is known to affect chromatin organization in hepatocytes of non-obese diabetic (NOD) mouse strain. Sirt1, a NAD<sup>+</sup>-dependent deacetylase, has been related to cellular metabolic changes, acting as a nutritional sensor. Together with the transcription factors PGC-1α and Foxo1, Sirt1 could change the expression profiles of genes involved in cell adaptation and response to hyperglycemic conditions. The aim of this study was to establish possible changes in the expression of the genes *ApoE*, *Igfbp1* and *Foxo1* and whether they are associated with an epigenetic signature involving sirtuins, in hepatoma HepG2 cells under hyperglycemic conditions.

**Materials and methods:** HepG2 cells cultivated in an insulin-containing normoglycemic medium (NM) were used as a control (Group 1). Group 2 consisted in cells treated for 48 h with a high glucose medium (HGM) in absence of insulin, in order to simulate a type I DM condition. Group 3 con-

sisted of cells treated as cells of group 2 but that were subsequently returned to NM for 24 h. Cells treated with NM and HGM containing nicotinamide (NIC), a sirtuin inhibitor, for 6 h, were groups 4 and 5, respectively. qPCR was used to evaluate *Apoe*, *Igfbp1* and *Foxo1* gene expressions. The abundance of the H3K9me2 and H3K9Ac markers was analyzed in the promoters of these genes by ChIP.

**Results:** An increase in gene expression was observed in cells of the group 2 in comparison to those of group 1 (*Apoe*:  $3.6 \pm 0.3$ , *Igfbp1*:  $5.3 \pm 0.9$  and *Foxo1*:  $1.5 \pm 0.2$  fold). These expressions returned to basal levels in cells of group 3 (*Apoe*:  $1.6 \pm 0.1$ , *Igfbp1*:  $1.0 \pm 0.1$ ; *Foxo1*:  $0.8 \pm 0.1$  fold). Treatment with NIC in NM (group 4) elicited a different expression response for each gene: while *Apoe* was not affected, *Igfbp1* presented an increase, similarly to group 2 ( $4.7 \pm 0.8$  fold), and *Foxo1* presented a decrease ( $0.6 \pm 0.1$  fold). In cells of group 5 gene expression was similar only to that of group 2. When epigenetic marks on the promoters of these genes were analyzed in cells of groups 2 and 3, a progressive loss of H3K9me2 and H3K9Ac was detected (Table). Whereas a general increase in both markers was found in cells of group 4, no significant change was detected in cells of group 5 (Table).

**Conclusion:** Changes in gene expression in the studied genes, caused by hyperglycemia, showed to be rapidly modulated according to the cell medium composition. Sirtuin activity seemed to be inhibited by HGM, because treatment with NIC showed results similar to those obtained with treatment with HGM only. However, both H3K9Ac and H3K9me2 epigenetic markers presented the same and continuous response. This could indicate either a slower response to changes in medium conditions or a different epigenetic signature of these markers. Difference in sirtuin response apparently occurred only under NM conditions, which could indicate an inactivity of those proteins under HGM conditions in the absence of insulin.

### Sex steroid-induced changes in circulating monocyte chemoattractant protein-1 levels may contribute to metabolic dysfunction in obese men

D.M. Ouwens<sup>1</sup>, M. Bekaert<sup>2</sup>, B. Lapauw<sup>2</sup>, S. Lehr<sup>1</sup>, S. Hartwig<sup>1</sup>, D. Herzfeld de Wiza<sup>1</sup>, M. Schiller<sup>1</sup>, W. Passlack<sup>1</sup>, Y. Van Nieuwenhove<sup>2</sup>, Y.E. Taes<sup>2</sup>, H. Sell<sup>1</sup>, J. Eckel<sup>1</sup>, J.M. Kaufman<sup>2</sup>, J.B. Ruige<sup>1</sup>;

<sup>1</sup>Biochemistry, German Diabetes Center, Duesseldorf, Germany,

<sup>2</sup>Endocrinology, Ghent University Hospital, Ghent, Belgium.

**Background and aims:** Low testosterone accompanied by elevated estradiol associates with the development of metabolic dysfunction in men. Here we explored the hypothesis that alterations in sex steroid levels induce metabolic dysfunction through adipokines.

**Materials and methods:** Circulating levels of sex steroids were quantified by LC-MS/MS and levels of 28 adipokines were determined using magnetic-bead based assays and ELISA in a cross-sectional study of morbidly obese men (n=37, of which 23 had type 2 diabetes (DM2)) and aged-matched controls (n=20), as well as in a randomized clinical trial with healthy young men (n=20) in which obesity-related alterations in sex steroid levels were mimicked by treatment with an aromatase inhibitor plus estradiol patches.

**Results:** Testosterone levels were lowest in morbidly obese men with DM2, intermediate in obese men without DM2, and highest in control men (all  $P < 0.01$ ). Estradiol levels were increased in obese men without DM2 as compared to control men or obese men with DM2 ( $P < 0.05$ ). Adiponectin and omentin levels were lower in obese men, while dipeptidyl peptidase 4, interleukins (IL) IL1Ra, IL5, IL8, IL10, IP10, leptin, and plasminogen-activated inhibitor 1 levels were elevated versus control men (all  $P < 0.05$ ). Adipokine levels were not different between obese men with and without DM2. Testosterone associated negatively and estradiol positively with circulating levels of multiple pro-inflammatory cytokines, including IL1Ra, IL5, IL6, IL10, leptin, monocyte chemoattractant protein 1 (MCP1), and vascular endothelial growth factor (all  $P < 0.05$ ). The associations with estradiol, but not with testosterone, remained significant after adjusting for adipocyte cell size. In a separate clinical trial in healthy young males, circulating levels of MCP1 increased following an intervention in which testosterone was lowered and estradiol levels were raised (figure 1).

**Conclusion:** Alterations in sex steroid levels may contribute to metabolic dysfunction through adverse effects on adipokine levels in obese men. The direct adverse effects on MCP1, a chemokine highly linked to the development of metabolic dysfunction, were substantiated *in vivo* in a trial mimicking obesity-related alterations of sex steroid levels in healthy young males.

**Figure 1.** Changes in MCP1-levels before (day 0) and after (day 7) intervention with an aromatase inhibitor (letrozole) and estradiol patches to lower testosterone and raise estradiol (group letrozole + E<sub>2</sub>), versus intervention with an aromatase inhibitor only to raise testosterone and lower estradiol (group letrozole) in healthy young men. P-values were calculated using a paired Student t-test; \*\*,  $P < 0.01$ .

### Anti-HSP70 levels and the metabolic syndrome: the Casale Monferrato study

B. Lorenzati, S. Giunti, F. Barutta, S. Pinach, P. Cavallo-Perin, G. Bruno, G. Gruden;

Department of Internal Medicine, University of Turin, Italy.

**Background and aims:** The metabolic syndrome (MS), a cluster of metabolic abnormalities characterized by a low-grade inflammation and a pro-oxidant state, is associated with increased risk of developing both type 2 diabetes (T2DM) and cardiovascular disease. Heat shock protein 70 (HSP70) is an intracellular, highly conserved polypeptide important for cell survival. In stress

conditions, HSP70 can be exposed on the plasma membrane and/or released into the circulation, eliciting an immune response. A reduction in HSPs has been proposed to contribute to impaired insulin signaling/responsiveness characteristic of T2DM. Our aim was to investigate the potential association between circulating anti-HSP70 and MS.

**Materials and methods:** A nested case-control study was performed within the Casale Monferrato Study (CM). The CM study recruited 3,700 non-diabetic subjects, aged 45–74 years, randomly identified through the files of the resident Casale Monferrato population. The present analysis included subjects ( $n=1552$ ) with plasma creatinine levels  $< 2$  mg/dl, CRP levels  $< 3$  mg/dl, and without cardiovascular disease. Among them, we selected as cases ( $n=251$ ) those who had MS (NCEP-ATPIII) and as controls ( $n=170$ ) those without any component of the MS. Stored plasma samples available for the analyses were 180 for cases and 136 for controls. The sample size provides a power of 82% ( $\alpha=0.05$ ) to detect a difference in log-anti-HSP70 within the cohort of at least one-third of standard deviation. Serum levels of anti-HSP70 were measured by a commercial ELISA kit (Stressgen).

**Results:** Anti-HSP70 levels were higher in subjects with MS than in those without MS, even after adjustment for age and sex (118.2 vs. 106.1  $\mu\text{g/ml}$ ,  $p=0.02$ ). In logistic regression analyses, higher levels of log-anti-HSP70 conferred higher ORs for MS and this remained statistically significant after adjustment for age and sex [OR = 2.02 (1.12–3.66)]. In this model, trend of ORs across quartiles of anti-HSP70 was statistically significant ( $p=0.04$ ). Subjects with anti-HSP70  $> 108.0$   $\mu\text{g/ml}$  had 77% increased odds of having MS compared to those with levels  $\leq 108.0$   $\mu\text{g/ml}$ .

**Conclusion:** In this cohort of non-diabetic subjects at low cardiovascular risk, we found an independent association between anti-HSP70 and MS. This suggests that anti-HSP70 may be a novel marker of MS.

### Blood monocytes in type 2 diabetes have an altered microRNA profile

L. Baldeon Rojas<sup>1</sup>, V. Rockova<sup>2</sup>, K. Derks<sup>3</sup>, A. van Oudenaren<sup>1</sup>,

H.A. Drexhage<sup>1</sup>, A.J. van Zonneveld<sup>4</sup>, P.J.M. Leenen<sup>1</sup>;

<sup>1</sup>Immunology, Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>Biostatistics and Hematology, Erasmus MC, Rotterdam, <sup>3</sup>Genetics, Erasmus MC, Rotterdam, <sup>4</sup>Nephrology, Leiden University Medical Center, Netherlands.

**Background and aims:** Type 2 diabetes is associated with low-grade systemic inflammation. This is reflected, amongst others, in vascular complications caused by increased endothelial damage and decreased ability to repair. Bone marrow-derived endothelial progenitor cells (EPC) play an essential role in repairing vascular damage and these cells are functionally inhibited in diabetes. Myeloid EPC are closely related to monocytes/macrophages and also these cells show increased pro-inflammatory activity in type 2 diabetes. To understand the alterations of monocytes at the molecular level and to determine the putative role of microRNAs, we determined microRNA profiles of monocytes from individuals with type 2 diabetes.

**Materials and methods:** From 34 type 2 diabetic patients and 25 age- and sex-matched controls, from two cohorts (German and Ecuadorian), CD-14positive blood monocytes were isolated using Ficoll and MACS separation. Total RNA was used to perform microRNA profiling in an LNA-based array. Differential expression and prediction signature were assessed using correction for multiple testing.

**Results:** Of 711 microRNAs tested, we found 142 microRNAs to be differentially expressed by CD14<sup>+</sup> monocytes from patients with type 2 diabetes compared to matched controls. Furthermore, a set of 15 microRNAs could serve as optimal predictor of disease. Cluster analysis on the basis of the expression of these microRNAs gave a high degree of distinction between patient samples and controls. Using Ingenuity pathway analysis, we corroborated that mainly inflammatory networks involving TNF, NF- $\kappa$ B and its regulatory molecules (SOCS) are potential targets of these microRNAs.

**Conclusion:** Our current findings indicate that the microRNA profile of monocytes in type 2 diabetes is significantly altered. Thus, microRNAs may play an important role in the inflammatory dysregulation of the cells and their functional incompetence in maintaining endothelial integrity.

### Glucose metabolism disorders in kidney transplant recipients associate with higher level of interleukin 1 receptor

A. Witkowska<sup>1</sup>, A. Strozik<sup>1</sup>, S. Gorczyńska - Kosiorz<sup>1</sup>, W. Trautsohl<sup>1</sup>, A. Owczarek<sup>2</sup>, G. Wystrychowski<sup>1</sup>, K. Nabrdalik<sup>1</sup>, W. Grzeszczak<sup>1</sup>, J. Gumprecht<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, Diabetology and Nephrology, Medical University of Silesia, Zabrze, <sup>2</sup>Division of Statistics, Medical University of Silesia, Sosnowiec, Poland.

**Background and aim:** Diabetes is a chronic inflammatory disease promoted by alteration of function of immune system. Renal transplant recipients are at risk of diabetes depending on interplay of immune system disorders characteristic of chronic kidney disease, and modulations of systemic pro- and anti-inflammatory cytokines expression by immunosuppressive therapies. This study aimed to assess whether glucose metabolism disorders observed in patients after renal transplantation are associated with changes in serum level of anti-inflammatory interleukin 10 (IL-10), pro-inflammatory interleukin 1- $\beta$  (IL-1 $\beta$ ) or its receptor (IL-1R).

**Materials and methods:** Seventy-seven patients (45 men and 32 women, aged  $47.6 \pm 11.1$  years) after kidney transplantation, not affected with acute or chronic concomitant inflammatory diseases (potentially influencing serum cytokine level), receiving standard schemes of immunosuppressive therapy, were studied. Upon the results of the oral glucose tolerance test, 43 patients with glucose metabolism disorder (impaired fasting glucose/impaired glucose tolerance or diabetes) and 34 with euglycemia (fasting serum glucose  $< 100$  mg/dl) were identified. The serum levels of IL-1 $\beta$ , IL-1R and IL-10 were measured using ELISA test and compared between the two studied groups with adjustment for age, sex, BMI, serum creatinine, CRP level and lipid profile. T-student test (in case of normal distribution or after normalisation) was applied to discern factors differentiating the patients with normoglycemia or glucose metabolism disorder. Distribution of variables was evaluated by the Shapiro-Wilk test. Homogeneity of variances was assessed by the Levene test.

**Results:** Serum IL-1R level differed statistically significantly between the analyzed groups with higher values in patients with glucose metabolism disorders (Me: 733.4 vs. 429.1;  $p < 0.001$ ). The prediabetic or diabetic patients were also older ( $50.0 \pm 11.6$  vs.  $44.5 \pm 10.0$ ;  $p < 0.05$ ), had higher BMI values ( $28.0 \pm 4.7$  vs.  $25.7 \pm 2.3$ ;  $p < 0.05$ ) and lower HDL level ( $1.27 \pm 0.30$  vs.  $1.57 \pm 0.66$ ;  $p < 0.05$ ). There were no differences in serum levels of CRP, uric acid, creatinine, total and LDL cholesterol and triglycerides. The studied serum level of IL-1 $\beta$  and IL-10 did not differ statistically significantly between the analyzed groups, either.

**Conclusion:** Glucose metabolism disorders in transplant recipients are associated with a rise in IL-1R serum level. This suggests potential role of IL-1R as a marker or the therapeutic goal in these patients, however, larger studies should yield verification of this finding.

## 658

### Targeting the association of calgranulin B (S100A9) with insulin resistance and type 2 diabetes

J.M. Mercader<sup>1</sup>, E.J. Ortega<sup>2</sup>, J.M. Moreno-Navarrete<sup>2</sup>, M. Sabater<sup>2</sup>, N. Pueyo<sup>2</sup>, G. Pardo<sup>2</sup>, M. Serrano<sup>2</sup>, W. Ricart<sup>2</sup>, E. Delgado<sup>3</sup>, R. Burcelin<sup>4</sup>, G. Frühbeck<sup>5</sup>, F. Bosch<sup>6</sup>, G. Mingrone<sup>7</sup>, A. Zorzano<sup>6</sup>, J.M. Fernandez-Real<sup>2</sup>;

<sup>1</sup>Joint IRB-BSC program on Computational Biology, Barcelona, Spain, <sup>2</sup>Department of Diabetes, Endocrinology and Nutrition (UDEN), Institut d'Investigació Biomèdica de Girona (IdIBGi), Girona, Spain, <sup>3</sup>Hospital Central de Asturias, Oviedo, Spain, <sup>4</sup>INSERM Unité 858, Institut de Médecine Moléculaire de Rangueil, Toulouse, France, <sup>5</sup>Clínica Universitaria de Navarra, Pamplona, Spain, <sup>6</sup>Departament de Bioquímica i Biologia Molecular, Institute for Research in Biomedicine (IRB Barcelona), Spain, <sup>7</sup>Institute of Internal Medicine, Rome, Italy.

**Background:** Extensive efforts are being made trying to identify genes involved in the development of type 2 diabetes (T2D). *Calgranulin B* (S100A9) was recognized as a candidate T2D gene in a platform based on the genomic profiling of muscle from a rodent model of T2D, identifying the human orthologs of genes localized in T2D susceptibility regions.

**Methods:** Circulating and S100A9 expressions in human muscle and adipose tissue, isolated fat cells, and in mice models were evaluated. A common 5'-upstream SNP (rs3014866) for S100A9 was studied ( $n=1,450$ ). The effects of weight loss on circulating and S100A9 mRNA in adipose tissue were also investigated. Treatments *in vitro* with recombinant S100A9 were performed.

**Results:** *S100a9* expression was increased in the muscle of diabetic mice, and further confirmed in human muscle from insulin resistant subjects. The rs3014866 SNP was found to be significantly associated with circulating S100A9, and the risk of T2D (TT carriers having increased S100A9 and 28% lower risk). Indeed, increased circulating S100A9 and adipose tissue expression in TT carriers run in parallel to decreased fasting glucose and glycated hemoglobin. In agreement with these results, metformin led to increased S100A9 expression in *ex vivo* treated human adipose tissue explants. On the other hand, obese subjects showed a compensatory increase in circulating S100A9 and adipose tissue expression, as demonstrated by decreased levels after weight loss. While lipopolysaccharide led to increased *S100a9* mRNA in fat from mice, recombinant S100A9 down-regulated inflammation in adipocytes.

**Conclusion:** Current findings support the strategy of testing differentially expressed genes in mice, and their human orthologs in hot genetic regions for T2D. The increased S100A9 levels reported for obesity and insulin resistance may be envisioned as a compensatory mechanism for inflammation.

### B- and T-cell deficiency does not protect from obesity-induced insulin resistance and inflammation

D.B. Ballak, R. Stienstra, A. Hijmans, L.A.B. Joosten, M.G. Netea, C.J. Tack; General Internal Medicine, Radboud University Medical Centre, Nijmegen, Netherlands.

**Background and aims:** Obesity is associated with development of chronic low grade inflammation that arises from adipose tissue. Obesity-induced inflammation is associated with insulin resistance and morphologically characterized by macrophage influx into the adipose tissue. More recently, various other immune cells including B- and T-cells have been shown to participate in modulating adipose tissue inflammation during the development of obesity. Here we tested the effect of the absence of both B- and T-cells in mice on the development of obesity-induced insulin resistance and inflammation. **Material and methods:** Wild-type and *Prkdc<sup>-/-</sup>* SCID animals, lacking both B- and T-cells, were given a low-fat (LFD) or high-fat (HFD) diet for 8 weeks to induce obesity.

**Results:** FACS analysis revealed that HFD-feeding modulated the influx of B and T-cells into adipose tissue of obese animals. After 8 weeks of high fat diet feeding, SCID mice displayed a lower bodyweight paralleled by lower circulating leptin levels, a reduction in adipose tissue mass and smaller adipocytes compared to wild-type mice. Circulation levels of insulin were increased due to the HFD feeding in both genotypes, although absolute values were significantly lower in SCID animals. Despite a lower bodyweight after HFD-feeding, gene expression levels of CD68, F4/80, MCP-1 and TNF- $\alpha$  in white adipose tissue were higher, indicating that SCID mice were not protected against HFD-induced inflammation. Moreover, the inflammatory status of the adipose tissue appeared to be more pronounced as stimulation of bone-marrow derived macrophages with conditioned medium from adipose tissue explants of HFD-fed SCID mice led to increased IL-6 and KC levels compared to medium obtained from adipose tissue of HFD-fed wild-type animals. Additionally, systemic KC levels were increased in SCID-mice as compared to wild-type animals. In line with these results, glucose tolerance was impaired in SCID mice after HFD feeding.

**Conclusion:** B- and T-cell deletion does not protect against HFD-induced insulin resistance and inflammation. In contrast, SCID mice showed an increased pro-inflammatory status at the level of the adipose tissue. Our findings suggest that other immune cell populations drive the macrophage accumulation in adipose tissue.

## 660

### High-fructose corn syrup (HFCS) diet induces an NLRP-3 inflammasome-mediated response in the kidney: protection by PPAR $\beta/\delta$ agonist

E. Benetti, M. Collino, M. Rogazzo, M. Aragno, R. Mastrocola, R. Fantozzi; University of Turin, Italy.

**Background and aims:** Fructose-based sweeteners are the most commonly added sugars and High-Fructose Corn Syrup (HFCS: 55% fructose, 42% glucose and 3% higher saccharides) is the less expensive and most widely

used. Consumption of sugar-enriched foods and beverages has been associated with increased prevalence of obesity, insulin resistance, dyslipidemia and cardiovascular injury. However, the molecular mechanism(s) underlying sugar detrimental effects are not completely understood. We have recently demonstrated, in rats, that chronic exposure to a fructose- and cholesterol-enriched diet caused not only metabolic damage but also hepatic inflammation, decreased by pioglitazone, a selective agonist of the Peroxisome Proliferator Activated Receptor (PPAR) $\gamma$ . Here we investigated the deleterious effects of a HFCS-enriched diet, focusing on the renal toxicity of fructose, whose main metabolite is uric acid. As NLRP-3 (NOD-like receptor pyrin domain-containing 3) inflammasome is a recently discovered signaling pathway involved in insulin-resistance and obesity-induced inflammation, we have also studied whether it may contribute to the HFCS-induced pathological effects. We also evaluated whether selective activation of the less investigated PPAR isoform, PPAR $\beta/\delta$ , exerted protective effects.

**Materials and methods:** Male C57BL/6 mice (n=10 per group) were provided with a standard diet or a standard diet plus 15% HFCS for 7 months. Subset of animals were treated with the selective PPAR $\beta/\delta$  agonist GW0742 (1 mg/kg-1, p.o.) for the last 3 months. Body weight, drink and food intake, blood pressure and urine volume were recorded monthly. At the end of the treatment, glucose tolerance test was performed. The expression of PPAR $\beta/\delta$ , fructokinase, NLRP-3 and caspase-1 activation were assessed by western blot on liver and kidney specimens. Serum levels of uric acid and interleukin (IL)-1 $\beta$  were evaluated by ELISA. Data were assessed by one-way ANOVA followed by Bonferroni's post hoc test and a P value <0,05 was considered significant.

**Key results:** In comparison to standard diet, HFCS diet impaired glucose tolerance and induced hyperlipidemia (total cholesterol 3,86 $\pm$ 0,19 mmol/l versus 7,46 $\pm$ 0,25 mmol/L), hyperuricemia (3 $\pm$ 0,05 mg/dl vs 3,9 $\pm$ 0,1 mg/dl) and albumin/creatinine ratio increase (105 $\pm$ 3,3  $\mu$ g/mg vs 148 $\pm$ 1,6  $\mu$ g/mg). Notably, GW0742 evoked a significant improvement in lipid metabolism, insulin responsiveness, hyperuricemia and albuminuria. Interestingly, while HFCS diet evoked a two-fold increase in hepatic fructokinase and renal NLRP-3 expression, chronic GW0742 administration reported the protein levels back to control values. GW0742 ability to affect HFCS-induced NLRP-3 activation was confirmed by a significant reduction in renal caspase-1 processing. Consistently, the increase in serum IL-1 $\beta$  concentration due to HFCS exposure (105,7 $\pm$ 3,33 vs 76 $\pm$ 4,76 mg/dl) was reduced by 60% in the GW0742 group.

**Conclusion:** Our data clearly demonstrate that PPAR $\beta/\delta$  activation improves metabolic damage and reduces renal inflammation due to chronic exposure to the HFCS diet. Reduction in hepatic fructokinase and renal NLRP-3 inflammasome activity significantly contributes to the protective role of GW0742 against deleterious effects of high fructose exposure.

## 661

### TNF-alpha up-regulates TNF-alpha converting enzyme (TACE) in visceral adipose tissues via JNK and PKC activation

H. Motoshima, S. Kawasaki, T. Kondo, S. Hanatani, Y. Takaki, M. Igata, T. Matsumura, T. Senokuchi, T. Nishikawa, E. Araki; Metabolic Medicine, Kumamoto University, Japan.

**Background and aims:** Inhibition of TNF- $\alpha$  converting enzyme (TACE), which involves in production of mature TNF- $\alpha$ , resulted in improvement in glucose and insulin levels in diabetic animals, suggesting a crucial role of TACE activity in glucose metabolism. However, the tissue responsible for TACE activation is largely unknown.

**Materials and methods:** In this study, we investigated the impact of visceral adipose tissue (VAT) as a target of TACE activation. The expression and activity of TACE in C57BL/6 mice fed standard chow (SC) or high-fat diet (HF), KK and KKAY mice fed ad-libitum (KK-AL and AY-AL) or fed reduced amounts of SC (caloric restriction (CR); AY-CR) were studied by RT-PCR, western blot and TACE activity with a FRET analysis. Pharmacological inhibitors for JNK (SP600125; SP) and PKC (Go6983; Go) were used to investigate the signaling pathways.

**Results:** Compared with C57BL/6 mice fed SC, mice fed HF developed obesity and showed higher expression and activity of TACE. AY-AL mice were heavier and showed higher expression and activity of TACE in VAT compared with those of KK-AL mice. HF-fed C57BL/6 and AY-AL mice showed elevated phosphorylation of JNK and PKC in VAT compared with the controls. AY-CR mice had less body weight, lower glucose and insulin levels, and showed lower expression and activity of TACE in VAT compared with AY-AL mice, which were associated with reduced phosphorylation of the kinases. In in-

vitro study using 3T3-L1 adipocytes, TACE expression and activity increased 2–3-fold either by TNF- $\alpha$  or LPS stimulation, and pretreatment with SP or Go partially suppressed these events. Intraperitoneal injection of SP strongly reduced the TACE activity in VAT, and suppressed both JNK and PKC signaling in Ay-AL mice. In addition, TNF- $\alpha$  injected intraperitoneally induced TACE expression and increased JNK phosphorylation in VAT in C57BL6 mice.

**Conclusion:** These results indicate that expression and activity of TACE in VAT are up-regulated during the development of obesity at least in part via activation of JNK and PKC, and beneficial effects of CR on obesity-induced insulin resistance might be mediated in part by inhibition of TACE activity in VAT.

## 662

### INOS activity and the formation of peroxynitrite play a key role in amplifying NF $\kappa$ B transcriptional activity via the p38 mapk kinase pathway

K. Bellmann, R. Cabana, A. Charbonneau, A. Marette;

Centre de recherche de l'Institut universitaire de cardiologie et pneumologie de Québec, Canada.

**Background and aims:** Recent studies have shown that nitric oxide (NO) and various reactive nitrogen species (RNS) modulate the NF $\kappa$ B signaling pathway in settings of cancer development and apoptosis. Nevertheless, nothing is known about the role of iNOS in modulation of NF $\kappa$ B activity in metabolic tissues involved in insulin resistance. We have previously shown that the inducible nitric oxide synthase (iNOS) plays an important role in mediating insulin resistance upon lipid challenge and that this was mediated by an iNOS-dependent tyrosine nitration of insulin signaling proteins including Akt. Moreover, we observed a strong reduction of insulin-mediated glucose disposal after treatment with LPS during euglycemic-hyperinsulinemic clamps, which was completely abrogated in mice lacking iNOS. This protection was associated with improved insulin-mediated suppression of hepatic glucose production and increased liver Akt activation in iNOS-KO mice underlining the important role of iNOS in hepatic insulin resistance. Here, we evaluated whether iNOS or the RNS peroxynitrite (ONOO-) can modulate hepatic NF $\kappa$ B activation in in vitro inflammatory settings via the MAP kinase p38.

**Materials and methods:** The rat hepatic cell line (Fao) was treated with a cytokine mixture (TNF $\alpha$ , IFN $\gamma$ , IL-1 $\beta$ ) in the presence of ONOO- or the selective iNOS inhibitor 1400W to block inflammatory iNOS induction. The activation of the NF $\kappa$ B pathway was evaluated in total cell lysates and the nuclear translocation of RelB/p50 as well as its transcriptional activity were analyzed.

**Results:** Treatment of Fao cells with cytokines led to increased phosphorylation of IKK, RelB and to the degradation of I $\kappa$ Ba though this was not at all affected in the presence of ONOO- or in by iNOS inhibition using 1400W. Analysis of nuclear events revealed that ONOO- increased NF $\kappa$ B nuclear transcription factor activity by 50% as well as NF $\kappa$ B-driven luciferase activity by 20%, both of which were reduced by 1400W by 20%. Cytokine induced nuclear translocation of RelB or p50 were not affected by ONOO- or 1400W. Hence, we evaluated their effects on p38 MAP kinase activation known to play a role on the binding of the transcription coactivator p300 to NF $\kappa$ B. Interestingly, we observed a 2fold increase of p38 phosphorylation after treatment with cytokines in the presence of ONOO- and a reduction of p38 phosphorylation in the presence of the iNOS inhibitor 1400W by 21%. Furthermore, NF $\kappa$ B driven luciferase activity was reduced by 30% when p38 activity was inhibited.

**Conclusion:** We conclude that iNOS induction contributes to hepatic NF $\kappa$ B activation via formation of peroxynitrite by affecting p38 phosphorylation suggesting that this feedforward mechanism may contribute to exacerbate inflammation, thereby further impairing insulin signaling and hepatic insulin action.

### CD40 and costimulatory molecules B7.1, B7.2 in adipocytes-leukocytes interactions

A. Chatzigeorgiou, T. Chavakis;

Department of Internal Medicine III and Institute of Physiology, Dresden University of Technology, Germany.

**Background and aims:** Macrophages and lymphocytes are implicated in obesity-related adipose tissue inflammation and may interact with adipocytes.

The costimulatory systems CD40-CD40L and B7.1/B7.2-CD28 are essential for T cell activation and inflammatory reactions, yet the contribution of these pathways in the intercellular communications between inflammatory cells and adipocytes during adipose tissue inflammation remains unclear. Here, we assessed expression and function of these costimulatory systems in the interactions between adipocytes and lymphocytes and macrophages.

**Materials and methods:** Differentiated 3T3-L1 adipocytes and bone marrow derived macrophages (BMDM) were treated with palmitate and TNF and also with CD40L and the expression of CD40, B7.1, B7.2, chemokines and adhesion molecules was evaluated with qPCR. Migration of bone marrow mononuclear cells (BMMNCs) towards supernatants from adipocytes pre-treated with TNF and CD40L, as compared to control supernatants, was assessed. The contribution of CD40, B7.1 and B7.2 and their ligands to the adhesion between adipocytes and CD3+ T cells was evaluated.

**Results:** TNF upregulates the expression of CD40, B7.2, MCP-1, CCL3, CCL4, CCL5, ICAM-1 and VCAM-1, whereas palmitate increases the expression of CCL4 and ICAM-1 on adipocytes. CD40, B7.1, B7.2, MCP-1, CCL3 and CXCL2 are overexpressed on BMDMs upon stimulation with palmitate (without or together with TNF), although TNF alone did not upregulate the expression of these genes. Stimulation of adipocytes with CD40L for 4 hours increased the expression of CD40, MCP-1 and CCL4 (1,62 $\pm$ 0,59, 1,92 $\pm$  0,73 and 1,84 $\pm$  0,84 fold change respectively) and for 24 hours the expression of MCP-1, CCL4, CCL5 (3,11 $\pm$ 0,96, 2,43 $\pm$ 0,43 and 2,52 $\pm$ 0,63 fold change respectively). Supernatants of CD40L-pretreated adipocytes induced elevated migration of BMMN cells, as compared to control supernatants (147,83%  $\pm$  8,26%). In contrast, CD40, B7.1 and B7.2 did not contribute to the adhesion between adipocytes and CD3+ T cells.

**Conclusion:** The inflammation-dependent upregulation of CD40 on adipocytes in the adipose tissue and/or the recruitment of CD40L-expressing T cells can stimulate chemokine expression in adipocytes, thereby mediating macrophage accumulation in the adipose tissue. Macrophages in turn are characterized by lipid-mediated CD40-, B7.1- and B7.2-overexpression, a phenomenon that may contribute to perpetuation of adipose tissue inflammation.

### High fat diet impairs glucose tolerance but not mitochondrial function in skeletal muscle of C57Bl/6J mice

K. Haas<sup>1,2</sup>, M. Aichler<sup>3</sup>, M. Conti<sup>4</sup>, S. Loric<sup>5,6</sup>, A. Walch<sup>7</sup>, H. Daniel<sup>8</sup>, M. Klingenspor<sup>1</sup>;

<sup>1</sup>Molecular Nutritional Medicine, Technical University Munich, Freising, Germany, <sup>2</sup>Institute for experimental genetics, Helmholtz Center Munich, Neuherberg, Germany, <sup>3</sup>Research Unit for Analytical Pathology, Helmholtz Center Munich, Neuherberg, Germany, <sup>4</sup>Clinical Biochemistry Laboratory, APHP Bicêtre University Hospital, Le Kremlin-Bicêtre, France, <sup>5</sup>Clinical Biochemistry and Genetics Laboratory, APHP Henri Mondor University Hospital, Créteil, France, <sup>6</sup>INSERM Unit 955, Faculté de Médecine, Créteil, France, <sup>7</sup>Research Unit Analytical Pathology, Helmholtz Center Munich, Freising, Germany, <sup>8</sup>Molecular Nutrition Unit, Technical University Munich, Freising, Germany.

**Background and aims:** Oxidative stress and mitochondrial dysfunction have been suggested as major contributors to the ageing process as well as the development of insulin resistance and type 2 diabetes. Mitochondria are controversially discussed as the missing link between chronic overnutrition and the loss of insulin sensitivity in peripheral tissues. In this study we used diet-induced obesity in juvenile and adult male C57Bl/6J mice as a model to analyse mitochondrial morphology, respiratory capacity and redox status in the skeletal muscle.

**Materials and methods:** Male C57Bl/6J mice either at 8 or 52 weeks of age received a high fat diet (48% kcal from fat mainly from palm-oil) or a standard diet (12% kcal from fat) for 9 weeks. Blood glucose was monitored during ipGTT. Plasma samples were prepared for insulin measurements (ELISA). A mitochondrial fraction was isolated from skeletal muscle. An array of markers for mitochondrial activity, oxidative stress and redox status was analysed in m. gastrocnemius using a commercial analytical platform. Mitochondrial morphology was investigated in m. gastrocnemius of young mice prepared for electron microscopy. Statistical analysis was performed using 2-way ANOVA.

**Results:** Robust body weight gain and progression in glucose intolerance together with elevated fasting insulin levels was seen in both age groups on high fat diet. Diet and age-related effects on cellular antioxidative mechanisms were only observed in the glutathione redox system. High fat diet elevated the GSSG levels and accordingly glutathione reductase which was generally more active in aged mice compared to young. Malondialdehyde, an indirect marker of oxidative stress, was neither affected by age nor by diet. Enzymatic activity of the respiratory chain complexes and energy charge was unchanged in all groups. Hydrogenperoxide levels measured in isolated mitochondria respiring on fatty acids increased with age but were not influenced by high fat diet in young mice and even tended to be reduced in high fat fed aged animals compared to controls. Morphology of skeletal muscle mitochondria in young animals was normal.

**Conclusion:** C57Bl/6J mice are widely used to study obesity with changes in glucose homeostasis and insulin secretion. We investigated effects of age and a high fat diet on the mitochondrial morphology and metabolism in skeletal muscle. The dietary challenge led to a constitutive change in glucose tolerance but did not reveal major metabolic lapse. Adaption of the glutathione redox system seems to sufficiently quench ROS released by mitochondria in aged animals in order to maintain full functionality. These results argue against the hypothesis that mitochondrial “dysfunction” is responsible for deleterious effects on insulin action in skeletal muscle.

### Age- and genetic background-dependent inducibility of lipid catabolism in skeletal muscle by high-fat diet and by leptin in mice

J. Hansikova, V. Kus, Z. Macek Jilkova, P. Janovska, J. Kopecky; Department of Adipose Tissue, Institute of Physiology Academy of Sciences of the Czech Republic v.v.i., Prague, Czech Republic.

**Background and aims:** Obesogenic effect of dietary lipids is counterbalanced by stimulation of energy expenditure and lipid oxidation. We have described

recently that in obesity-resistant A/J mice, but not in obesity-prone C57Bl/6 (B/6) mice, feeding corn oil-based high-fat diet (cHF; lipids ~35% wt/wt) for 2 weeks after weaning resulted in the induction of lipid catabolism and non-shivering thermogenesis in the oxidative skeletal muscle, in correlation with changes in leptinemia. These results suggested a role for muscle nonshivering thermogenesis and lipid oxidation in the obesity-resistant phenotype of A/J mice and indicated that cHF diet could induce thermogenesis in oxidative muscle, possibly *via* the leptin-AMPK axis. The aim of the present study was to establish whether the induction of lipid catabolism by cHF diet in skeletal muscle could be also observed in adult mice.

**Materials and methods:** Male mice of the B/6 and A/J strains were maintained at temperature closed to thermoneutrality (30 °C). Both after weaning at 4 weeks of age and at 3 months of age (adult mice; mice weaned to chow diet), mice were randomly assigned to either chow or cHF diet. After 2 weeks of the differential dietary treatment, mice of each subgroup were injected either by leptin (6 µg/g of body weight) or by saline (at 8.00 a.m.; *n*=8). After 5 hours (at 1.00 p.m.), animals were anesthetized by pentobarbital and soleus muscle was used for the measurement of the rate palmitate oxidation using [<sup>1-14</sup>C]-palmitate, and cervical blood was collected for assessment of leptinaemia.

**Results:** In accordance with our previous study (see above), cHF diet could increase 1.5-fold palmitate oxidation in the soleus muscle in A/J (cHF, 322±19 vs. chow, 214±28 dpm/mg tissue; *p*<0.05) but not in B/6 mice (cHF, 289±41 vs. chow, 309±33 dpm/mg tissue). In response to the leptin injection, this activity was increased further in A/J mice (cHF, 412±49 vs. chow, 275±16 dpm/mg tissue; *p*<0.05). In contrast, in B/6 mice, palmitate oxidation was not affected (cHF, 362±28 vs. chow, 283±24 dpm/mg tissue). In adult A/J mice, no stimulation of palmitate oxidation by either cHF or by leptin was detected. In these mice, AMPK activator AICAR stimulated palmitate oxidation in the muscle about 1.3-fold, independent on the diet. In adult mice of both strains, higher leptinaemia was detected in the cHF-fed as compared with the chow-fed mice, and leptin levels were lower in A/J than in B/6 mice (A/J, cHF, 9.39±0.82 vs. chow, 3.84±0.46ng/ml; *p*<0.05; and B/6, cHF, 34.39±6.77 vs. chow, 5.51±0.90 ng/ml; *p*<0.05).

**Conclusion:** Dietary lipids could induce thermogenesis in oxidative muscle in the post-weaning but not in adult A/J mice. Our results suggest that induction of muscle nonshivering thermogenesis by dietary fat depends on muscle leptin sensitivity, which deteriorates with advanced age, depending on the genetic background of the mice.

### Acute effects of monounsaturated fat on postprandial lipaemia and gene expression in first degree relatives of subjects with type 2 diabetes

S. Gregersen<sup>1</sup>, A. Pietraszek<sup>1</sup>, S.B. Pedersen<sup>1</sup>, J.J. Holst<sup>2</sup>, K. Hermansen<sup>1</sup>;

<sup>1</sup>Endocrinology and Metabolism, Aarhus University Hospital, <sup>2</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, Panum Institute, Copenhagen University, Denmark.

**Background and aims:** Subjects with type 2 diabetes (T2D) and their first degree relatives (REL) have increased risk of cardiovascular disease (CVD). Postprandial triglyceridaemia (PPL), influenced by diet, is an independent risk factor for CVD. Dietary fat elicits increased PPL in T2D compared with healthy controls (CON), but our knowledge on PPL responses to fat in REL is sparse. Our aim was to test the hypothesis that REL respond to a monounsaturated fatty acids (MUFA)-challenge with larger PPL than CON and that MUFA exert a differential impact on incretin responses and on expression of genes involved in carbohydrate and lipid metabolism in muscle and adipose tissue of REL and CON.

**Materials and methods:** 17 REL and 17 CON consumed a meal with 72 energy percent from MUFA (macadamia nut oil). Plasma triglycerides, free fatty acids, insulin, glucose, glucagon-like peptide 1, glucose-dependent insulinotropic peptide and ghrelin were measured at baseline and regular intervals until 4 h postprandially. Muscle and adipose tissue biopsies were taken at baseline and 210 min after the meal. Gene expression was determined using a real-time qPCR system.

**Results:** The MUFA-rich meal did not elicit different responses in PPL, insulin, glucose, incretins or ghrelin between REL and CON. Several genes were differentially regulated in muscle and adipose tissue of REL and CON. In muscle, several genes were up-regulated in CON in response to the MUFA-rich meal: *CD36*, *UCP3*, *PNPLA2* and *NR1H3*. In adipose tissue, *UCP3*, *PIK3R1*, *PRKCD*, *PRKQ*, *HK2* and *PPARGC1A* were up-regulated in response to the meal in CON, while *PDP1* was up-regulated in REL. The changes from base-

line till 210 min in expression of *ACSL1* and *PRKCD* in adipose tissue did not reach significance within groups, but differed significantly between REL and CON.

**Conclusion:** A MUFA-rich meal elicits similar PPL, insulin and incretin responses in REL and CON. MUFA has differential impact on gene expression in muscle and adipose tissue in a pattern pointing towards early defects in lipid metabolism in REL.

### Determining the role of skeletal muscle macrophages in type 2 diabetes

D. Patsouris, J. Cao, A. Durand, M.-A. Chauvin, M.-C. Michalski, H. Vidal, J. Riessset;

Inserm U1060, Oullins, France.

**Background and aims:** Type 2 diabetes (T2D) is nowadays considered a low grade inflammatory disease characterized by adipose tissue macrophages (ATMs) accumulation. Whereas it is established that secretion of pro-inflammatory cytokines by ATMs interferes with insulin signaling, this is skeletal muscle tissue which is responsible for most of whole body glucose disposal. However so far, there is very little information describing the inflammatory status of this tissue in the context of T2D. The aim of our project was hence to determine the role of skeletal muscle inflammation in the disease.

**Materials and methods:** We used three mice models of T2D. A genetic model (ob/ob), and two nutritional models. The first nutritional model consisted in feeding mice with a high fat diet (HFD, 45%) in absence or presence of rosiglitazone, an insulin sensitizing agent. The second nutritional model was mice fed with specific fatty acids such as palmitate (20%), an established saturated fatty acid with diabetogenic properties. In vivo delivery of adenovirus was realized by injecting viral particles with a needle in gastrocnemius of wild-type mice. In vitro chemotaxis assays were performed with macrophages cells exposed to myotubes conditioned media.

**Results:** we observed a striking correlation between intra-muscular pro-inflammatory cytokines (TNF $\alpha$ , IL1 $\beta$ ) or macrophages markers (F4/80, CD11b, CD11c) and insulin resistance in mice. Furthermore, inflammation observed in skeletal muscles of ob/ob mice is distinct to what is observed in adipose tissue and liver. We observed that the overexpression of MCP1 in gastrocnemius of wild-type mice was sufficient to alter insulin signaling in this tissue, which was correlated with an elevation inflammation. Finally, in vitro chemotaxis assays demonstrated that skeletal muscle macrophages might be recruited in response to the secretion of chemoattractants (MCP1) by myotubes exposed to excess fatty acids.

**Conclusion:** Our study indicates that T2D is associated with the recruitment of pro-inflammatory macrophages in skeletal muscle tissue, which may in turn induce or worsen the disease. This macrophages may be recruited in response to excess delivery of saturated fatty acids to myotubes, which may in turn induce the expression of chemokines such as MCP1.

### Macrophage-conditioned medium impairs insulin sensitivity in C2C12 myotubes through activation of mitogen-activated protein kinases

N.A. Talbot, C.P. Wheeler-Jones, M.E. Cleasby;

Comparative Biomedical Sciences, Royal Veterinary College, London, UK.

**Background and aims:** Skeletal muscle is the principal site for insulin-stimulated glucose disposal but its ability to utilise glucose is diminished by obesity-associated insulin resistance (IR) and the related elevation of plasma fatty acids (FA). Chronic sub-clinical inflammation, characterised by increased macrophage infiltration into obese adipose tissue is a hallmark of the insulin resistance syndrome. However, it is not known whether macrophages might play a role in mediating the local effects of elevated FA levels in muscle. Here we aimed to determine whether macrophage-conditioned medium would impair glucose disposal by cultured myotubes and the mechanisms involved.

**Materials and methods:** J774 macrophages (m $\phi$ ) were incubated with or without saturated FA (palmitic acid), unsaturated FA (palmitoleate) or lipopolysaccharide (LPS) for 8 hours to generate conditioned medium. Differentiated C2C12 myotubes were incubated with m $\phi$ -conditioned medium for 16 hours and the effects on intracellular signalling and glycogen synthesis assessed. In separate experiments, myotubes were pre-incubated for 1 hour

with DMSO, p38 MAPK inhibitors SB203580 (1 $\mu$ M) or BIRB796 (0.1 $\mu$ M), these inhibitors in combination, or JNK inhibitor V (1 $\mu$ M), prior to treatment with conditioned medium and assessment of the effects on signalling. 3-5 independent experiments were conducted in each case.

**Results:** Incubation of myotubes with palmitic acid-treated m $\phi$ -conditioned medium caused a 53% reduction in insulin-stimulated glycogen synthesis ( $p < 0.01$ ), accompanied by reductions in phosphorylation of PI3-kinase pathway intermediates of 57% for IRS-1 (Tyr612;  $p < 0.07$ ), 53% for Akt (Ser473;  $p < 0.005$ ), 56% for AS160 (Thr642;  $p < 0.05$ ) and 65% for GSK3 $\beta$  (Ser9;  $p < 0.01$ ). The conditioned medium activated MAP kinases, indicated by a 110% increase in JNK2 ( $p < 0.001$ ) and a 91% increase in p38 (Tyr182;  $p < 0.001$ ) phosphorylation. In addition, I $\kappa$ B $\alpha$  protein was reduced by 42% ( $p < 0.05$ ), together implying activation of stress/inflammatory pathways in myotubes. These changes were mirrored by the effects of LPS-conditioned medium. In contrast, palmitoleic acid-treated m $\phi$ -conditioned medium enhanced glycogen synthesis by 36% and increased phosphorylation of IRS-1, AS160 and GSK3 $\beta$ . When added in combination, palmitoleic acid-conditioned medium negated the effect of palmitic acid on signalling. To establish whether MAPK activation mediated the inhibitory effect of palmitic acid-treated m $\phi$ -conditioned medium on insulin signalling, conditioned medium was added to myotubes in the presence of specific inhibitors. Tyr612 phosphorylation of IRS1 was partially ameliorated by the addition of SB203580, SB203580 and BIRB796 in combination and by JNK inhibitor V. Inhibition of p38 MAPK using BIRB796 alone corrected 93% of the defect in IRS-1 phosphorylation. The defect in GSK3 $\beta$  Ser9 phosphorylation was ameliorated by the addition of both p38 MAPK and JNK inhibitors. The combination of SB203580 and BIRB796 corrected 80% of the defect in GSK3 $\beta$  phosphorylation induced by palmitic acid-treated m $\phi$ -conditioned medium.

**Conclusion:** These findings demonstrate that macrophage-derived factors may play a direct role in mediating the negative effects of elevated saturated plasma FAs on muscle insulin sensitivity. The mechanism of this effect involves inhibition of muscle insulin signalling by MAP kinases. Conversely, the presence of unsaturated FAs is protective against m $\phi$ -induced IR.

## 669

### The novel myokine YKL-40 is regulated by inflammatory cytokines and partially prevents TNF $\alpha$ induced pro-inflammatory signalling in primary human skeletal muscle cells

S.W. Görgens, K. Eckardt, J. Eckel;

Paul-Langerhans-Gruppe für Integrative Physiologie, Deutsches Diabetes-Zentrum, Düsseldorf, Germany.

**Background and aims:** The glycoprotein YKL-40 is a member of the 18 glycosyl hydrolase family, but has no chitinase activity. The lack of enzymic activity is attributed to the substitution of the catalytically essential glutamic acid residue in the active site of the glycohydrolases with a neutral amino acid. YKL-40 plays a role in tissue remodeling and inflammatory processes. Elevated serum levels of YKL-40 are found in patients with cardiovascular disease, type 2 diabetes and insulin resistance. Based on proteomic profiling of secreted proteins from primary human skeletal muscle cells (hSkMC) we identified YKL-40 as a novel myokine. However, the physiological role of YKL-40 remains largely unknown. The aim of this study was to investigate the regulation of YKL-40 in hSkMC by adipose tissue-derived factors and its potential autocrine function.

**Materials and methods:** hSkMC were *in vitro* differentiated, and RNA and protein samples were obtained every second day. Analyses of YKL-40 mRNA expression were done by quantitative RT-PCR while protein levels were analyzed using SDS-PAGE and Western Blot. In addition, supernatants were collected and analyzed for YKL-40 concentration by ELISA. Differentiated hSkMC were treated with recombinant human IFN- $\gamma$ , TNF $\alpha$ , IL-1 $\beta$ , IL-6, and adipocyte conditioned medium (CM) for 24h. Additionally, hSkMC were acutely stimulated with TNF $\alpha$  in combination with YKL-40. Effects on YKL-40 protein level and secretion as well as on NF $\kappa$ B and ERK1/2 phosphorylation were investigated by Western Blot.

**Results:** During differentiation of hSkMC we found a continuous decrease of protein level resulting in 30% YKL-40 protein level in differentiated hSkMC compared to myoblasts. YKL-40 mRNA expression strongly decreased by ~50% at the second day of differentiation. Thereafter, mRNA expression further decreased resulting in a downregulation of 80% in myotubes compared to myoblasts. The secretion of YKL-40 follows these patterns. While the supernatant of myoblasts contains  $1.12 \pm 0.24$  ng/ml YKL-40, we found only  $0.43 \pm 0.12$  ng/ml YKL-40 in the supernatant of myotubes. After incuba-

tion with CM we observed a 3.5fold increase of YKL-40 protein level. Treatment of hSkMC with the inflammatory factors IFN- $\gamma$ , TNF $\alpha$ , IL-1 $\beta$  and IL-6 significantly increased YKL-40 protein level (~2.5fold). In addition, IFN- $\gamma$ , TNF $\alpha$ , IL-1 $\beta$  and IL-6 treatment significantly increased the secretion of YKL-40 (~2fold). Furthermore, we observed a 2fold elevated mRNA expression after incubation with TNF $\alpha$ . While no effect of YKL-40 itself on NF $\kappa$ B and ERK1/2 phosphorylation was observed, we found a ~20% reduction of TNF $\alpha$ -induced NF $\kappa$ B and ERK1/2 activation when the cells were co-incubated with TNF $\alpha$  and YKL-40.

**Conclusion:** In summary, YKL-40 is a new myokine characterized by a differentiation dependent expression and secretion. CM, that contains the secretory output of adipocytes, as well as inflammatory cytokines are able to increase YKL-40 protein level and secretion in hSkMC. Thus, we suggest that YKL-40 is a new important factor in the crosstalk between adipose tissue and skeletal muscle. It may be speculated that the upregulation of YKL-40 has a protective meaning which may involve a modification of TNF $\alpha$ -induced pro-inflammatory signalling.

### Metabolic pathways regulated during adipogenesis - potential novel biomarkers for obesity

A. Halama<sup>1</sup>, M. Horsch<sup>1</sup>, G. Kastenmüller<sup>2</sup>, G. Möller<sup>1</sup>, M. Hrabé de Angelis<sup>1,3</sup>, J. Beckers<sup>1,3</sup>, J. Adamski<sup>1,3</sup>;

<sup>1</sup>Institute of Experimental Genetics, Genome Analysis Center, Helmholtz Zentrum München, <sup>2</sup>Institute of Bioinformatics and Systems Biology, Helmholtz Zentrum München, <sup>3</sup>Lehrstuhl für Experimentelle Genetik, Technische Universität München, Freising, Germany.

**Background and aims:** Obesity is a major risk factor for a number of diseases like diabetes type 2, insulin resistance or hyperglycemia. The mechanisms underlying adipogenesis are not well known yet therefore a study on cell adipogenesis using metabolomics combined with transcriptomics was performed to find new biomarkers of metabolic disorders.

**Materials and methods:** The mouse 3T3-L1 cell line, a widely used model to study the mechanisms of diabetes, was chosen to monitor changes in metabolite and gene expression levels at various stages of adipogenesis (8 time points set from day 0 to day 18). Metabolites and mRNA expression were determined with the AbsoluteIDQp180 kit from Biocrates and the MouseRef-8 v2.0 Expression BeadChip kit from Illumina, respectively. Cell differentiation was induced by insulin, dexamethasone and 3-isobutyl-1-methylxanthine (IBMX), and monitored with Oil Red O assay.

**Results:** We found significantly regulated genes correlating with changes in metabolite profile which exhibits characteristic pattern for different stages of adipogenesis. The most potent transcription factors like PPAR $\gamma$ , KLF5, KLF15 or GLUT4 known to be involved in promoting adipogenesis were strongly expressed in our study. Genes with highest score were further analyzed with Ingenuity System Pathway Analysis (IPA) and linked to lipid metabolism, metabolic disease, nutritional disease and cancer. Among metabolites, significantly regulated patterns were most prominent in phospholipids, lysophosphatidylcholines and sphingomyelins. Remarkable, other metabolites like amino acids (arginine, glutamine, serine and branched chain amino acids (BCAA)), carnitines (C0, C2, C3 and C4) and biogenic amines (putrescine, spermidine and spermine) are also regulated as cells undergo adipogenesis. Evaluation of the integrated transcriptomics data indicates an involvement in several affected pathways, as BCAA degradation, citric cycle, glycolysis, and glycerophospholipid synthesis. Moreover, de novo synthesized phosphatidylcholines affects metabolism of long-chain polyunsaturated fatty acids due to increased activity of phospholipase (PLA2) and fatty acid desaturase (FADS2).

**Conclusion:** This study shows the potential of combining metabolomics and transcriptomics in research of cellular processes, like adipogenesis. Especially molecules linked to BCAA metabolism and phospholipid synthesis like phosphatidylcholines seems to play a crucial role in fat cell differentiation therefore might be potential early biomarkers in the pathogenesis of obesity or diabetes.

### Transcriptome analysis of 3T3-L1 preadipocyte differentiation using RNA-seq reveals formerly unidentified differentially regulated genes

G. Mitterer<sup>1</sup>, S. Tauber<sup>2</sup>, F. Klinglmueller<sup>3</sup>, J. Husa<sup>1</sup>, J. Lindroos<sup>1</sup>, M. Jeitler<sup>1</sup>, O. Wagner<sup>1</sup>, M. Bilban<sup>1</sup>;

<sup>1</sup>Department of Laboratory Medicine, Medical University of Vienna, <sup>2</sup>Center for Integrative Bioinformatics Vienna, Max F. Perutz Laboratories, University of Vienna, <sup>3</sup>Center for Medical Statistics, Informatics and Intelligent Systems, Medical University of Vienna, Austria.

**Background and aims:** It is generally accepted that the regulation of adipogenesis prevents obesity. However, the mechanisms controlling adipogenesis have not been completely defined. Much of our knowledge of the molecular cascade regulating adipogenesis has come from transcriptome profiling data of adipocyte differentiation generated by DNA Microarray experiments. However, expression microarrays are limited due to a high background signal, the need for known template sequences, variabilities in probe hybridization and a fairly limited dynamic range. Hence, it is a plausible that important genes involved in adipogenesis are expressed below the reliable detection lev-

els of microarrays. In contrast, deep RNA sequencing (RNA-seq) is a recently developed approach for transcriptome profiling, where the RNA/cDNA species within a sample are sequenced, that does not suffer from the limitations described for Microarrays. Our goals were to use RNA-seq (i) to identify novel regulators of adipogenesis throughout 3T3-L1 preadipocyte differentiation and (ii) to compare sequencing data to results obtained from Microarrays.

**Materials and methods:** Murine 3T3-L1 preadipocytes were differentiated into mature adipocytes with 1.7  $\mu$ M insulin, 10 mM dexamethasone, 0.5mM 3-isobutyl-1-methylxanthine and 1  $\mu$ M Troglitazone. Total RNA was extracted on days 0, 2, 4 and 6 of 3T3-L1 preadipocyte differentiation and processed for transcriptome profiling either with Affymetrix Gene Level 1.0 ST arrays or the TrueSeq paired-end mRNA protocol on a Illumina HiSeq2000 platform. Differential gene expression was estimated using either fluorescence intensities (Microarray) or RPKM values (RNA-Seq). A fold-change (FC) of  $\pm 3.0$  was used to capture differentially expressed genes (DEG).

**Results:** Overall, the RNA-Seq approach identified a larger number of  $\pm 3.0$ -fold DEG in 3T3-L1 preadipocyte differentiation as compared with Gene 1.0 ST arrays on Days 2, 4 and 6 i.e. RNASeq: 2620, 4019 and 3972 genes versus Microarray: 443, 788 and 910. Importantly, the RNA-seq approach exclusively identified a substantial number of  $\pm 3.0$ -fold DEG in comparison to Gene 1.0 ST arrays i.e. 2190, 3287 and 3106 genes. Plotting FC values of RNA-seq versus Microarray revealed a population of genes that exhibited FC values at or near zero by Microarray analysis but exhibiting a wide range of FC values by RNA-seq, highlighting the sensitivity of the RNA-seq approach. The majority of upregulated DEG identified exclusively by the RNA-seq method, involved protein-DNA interactions, mitochondrial activity and carbohydrate metabolism, whereas downregulated DEG were regulators of extracellular matrix assembly, cell adhesion and proliferation.

**Conclusion:** Transcriptome profiling of adipocyte differentiation has improved our understanding of the molecular mechanisms of adipogenesis. Although microarrays have been instrumental in this regard, it is clear that these tools detect an incomplete set of DEG. Therefore the RNA-seq approach can be used to supplement these prior technologies, which could help identify novel target genes involved in adipogenesis in disease.

## 672

### Dietary regulation of VEGFb gene expression is related to its promoter DNA methylation levels

E. Garcia-Escobar<sup>1,2</sup>, S. Garcia-Serrano<sup>1,2</sup>, S. Morcillo<sup>1,3</sup>, G.M. Martin-Nuñez<sup>1,2</sup>, E. Rubio-Martin<sup>1,2</sup>, C. Gutierrez-Repiso<sup>1,2</sup>, F. Soriguer<sup>1,2</sup>, G. Rojo-Martinez<sup>1,2</sup>;

<sup>1</sup>Ciberdem CB07/08/0019 of the Instituto de Salud Carlos III, Spain, Malaga,

<sup>2</sup>Endocrinology and nutrition service, Carlos Haya hospital, Malaga,

<sup>3</sup>Endocrinology and research group, hospital de Cruces and university of the Basque Country UPV-EHU, Barakaldo, Spain.

**Background and aims:** Studying the transmembran fatty acid transport and its regulation has awakened a big interest because of its relationship with the development of different metabolic diseases such insulin resistance, obesity or diabetes. DNA methylation is a potent regulator of gene expression, which plays a crucial role in both physiology as well as pathology. It has been recently described the implication of the vascular endothelial growth factor B (VEGFb) in the tissue lipid uptake, which may open up the possibility for novel strategies to modulate pathological lipid accumulation in obesity or type 2 diabetes. The aim of this study is investigate the effect of dietary fatty acid composition in VEGFb gene expression regulation in rat adipose tissues, and whether this effect is related by DNA methylation modification on the VEGFb promoter.

**Materials and methods:** A group of rats (4 weeks old) was assigned to one of three different isoenergetic diets, each with a significantly different concentration of saturated, monounsaturated and polyunsaturated fatty acids (coconut oil diet, olive oil diet and sunflower diet respectively). Animals were feed during a month. Samples of omental and subcutaneous adipose tissue (OAT and SAT respectively) were immediately taken for the methylation and gene expression studies, and also samples of these tissues were taken for measurements of the tissue triacylglycerol fatty acid composition, and total tissue lipid accumulation.

**Results:** Neither animal or adipose pad weights varied according to diets, nor even tissues lipid accumulation. Tissue fatty acid composition was significantly different depending on the diet consumed in both tissue ( $p < 0.0001$  for all fatty acids studied). The VEGFb gene expression level was directly correlated with the lipid accumulation of each tissue (OAT:  $r = 0.49$ ;  $p = 0.04$ . SOT:  $r = 0.58$ ;  $p = 0.01$ ) and with tissue fatty acid composition. In both tissue,

VEGFb gene expression and promoter methylation levels were different regarding to the diet consumed (OAT gene expression:  $p = 0.002$ . SAT gene expression:  $p = 0.01$ . OAT promoter methylation:  $p = 0.005$ . SAT promoter methylation:  $p = 0.01$ ), being VEGFb gene expression and promoter methylation levels inversely correlated (OAT:  $r = -0.47$ ;  $p = 0.05$ . SAT:  $r = -0.56$ ;  $p = 0.03$ ), with the highest values of gene expression, and the lowest of promoter methylation, found in rats feed with coconut oil diet.

**Conclusion:** VEGFb gene expression in adipose tissue is associated with the increase in fat accumulation. The presented study shows that VEGFb gene expression is regulated by dietary fatty acid, and this regulation is related to the methylation level of VEGFb promoter region.

## 673

### A microdeletion within an obesity QTL on distal mouse chromosome 1 disrupts the *Ifi202b* gene which modulates preadipocyte proliferation

H. Vogel, T. Kanzleiter, S. Scherneck, V. Benz, R. Kluge, H.-G. Joost, A. Schürmann;

Experimental Diabetology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany.

**Background and aims:** The New Zealand Obese (NZO) mouse develops a polygenic disease pattern of obesity, insulin resistance, and dyslipoproteinemia resembling the human metabolic syndrome. By positional cloning we have recently discovered two genes (*Tbc1d1*, *Zfp69*) to participate in the development of the disease. In an outcross population of NZO and lean C57BL/6 (B6) mice we identified a major obesity QTL on distal chromosome 1 responsible for a body weight increment of 13 g in week 22.

**Materials and methods:** The conventional strategy of positional cloning, including generation of congenic lines with the lean B6 background, was used to reduce the critical fragment size and to characterize the phenotype of the QTL *Nob3* in more detail. Genes within the critical region were finally analyzed by sequencing and expression profiling.

**Results:** Introgression of a 38 Mbp segment of the QTL from NZO into B6 (B6.NZO-*Nob3*.38) increased body weight and fat mass. We generated additional congenic lines, tested them for the trait body weight and defined a genomic interval comprising 43 genes. Expression analysis of genes located in the critical fragment revealed the most striking difference for the gene *Ifi202b*, encoding for a transcriptional regulator. In tissues of homozygous B6-animals *Ifi202b* was undetectable but expressed in NZO mice. In contrast, expression of 10 related genes (*Ifi200* cluster) was significantly higher in B6 than in NZO-allele carriers. Consistent with a regulation of the cluster by *Ifi202b*, overexpression of its mRNA in skeletal muscle of B6 mice suppressed the expression of other genes within the cluster. Highest expression levels of *Ifi202b* were found in white adipose tissue. Suppression of *Ifi202b* in 3T3-L1 fibroblasts induce proliferation as detected by *Ki67* and *Pcna* expression. Sequence analysis identified a microdeletion including the first exon and the 5'-flanking region of the *Ifi202b* gene in B6.

**Conclusion:** We conclude that a microdeletion on chromosome 1 causes a loss of function of the *Ifi202b* gene in the B6 strain, affects the expression of other family members, and is responsible for decreased proliferation of preadipocytes leading to the obesity-suppressing phenotype of the B6 strain.

## 674

### Bone marrow fat: relationship with adiposity, insulin sensitivity, leptin and adiponectin

F. Amati<sup>1</sup>, Y. Sheu<sup>2</sup>, B.H. Goodpaster<sup>2</sup>, T. Prasad<sup>2</sup>, M.E. Danielson<sup>2</sup>, A.V. Schwartz<sup>3</sup>, J.A. Cauley<sup>2</sup>;

<sup>1</sup>University of Lausanne, Switzerland, <sup>2</sup>University of Pittsburgh, USA,

<sup>3</sup>University of California, San Francisco, San Francisco, USA.

**Background and aims:** Osteoporosis has been linked with lower bone marrow fat (BMF). With advancing age, differentiation of mesenchymal stem cells (MSCs) favors adipocytes instead of osteoblasts. Studies have found that lumbar bone mineral density (BMD) has an inverse relationship with BMF content. A positive association between visceral adipose tissue (VAT) and BMF has recently been shown in obese women, as well as a positive correlation between BMF and HbA1c in diabetic women. To our knowledge, no studies look at the relationship between BMF and regional fat depositions in men, or insulin resistance. Furthermore, a possible mechanistic explanation of the

impact of VAT on BMF could be the fact that MSCs are under the influence of adipokines such as leptin and adiponectin. Thus the objectives of this study were to observe the relationships of BMF with 1) VAT, abdominal subcutaneous adipose tissue (aSAT), calf subcutaneous (cSAT) and intermuscular (IMAT) adipose tissue, 2) markers of insulin resistance and 3) serum leptin and adiponectin in older men.

**Materials and methods:** Non-diabetic men were recruited for this study. BMF was measured by proton magnetic resonance spectroscopy in the lumbar vertebrae (L1–L3); percent body fat (BF) by dual-energy X-ray absorptiometry. VAT, aSAT, cSAT and IMAT were assessed by quantitative computed tomography. Fasting blood sugar (FBG) was measured enzymatic method; insulin, leptin and adiponectin were measured by RIA.

**Results:** 149 non diabetic men aged 74–95 years old participated in this study. Mean BMI was  $28.0 \pm 3.7$  kg/m<sup>2</sup> (range 18.8–38.4), mean BMF was  $55.5 \pm 11.1$ % (23.5–76.4) and mean BF was  $27.8 \pm 4.8$ % (17.5–40.9). Average BMF (L1–L3) was correlated with BF ( $r=0.35$ ,  $P=0.01$ ) and VAT ( $r=0.34$ ,  $P=0.01$ ), but was not correlated with BMI, aSAT, cSAT or IMAT. The relationship between BMF and VAT remained after controlling for BMI. After adjusting for age, BMF was associated with overall adiposity, VAT and leptin, but not with FBG, insulinemia, HOMA-IR or adiponectin (table).

**Conclusion:** The positive relationship between BMF and VAT observed in women is also true in older men. BMF was positively correlated with plasma leptin, but not with adiponectin or markers of insulin resistance. Further studies are needed to explore the relationship between VAT and BMF, particularly the hormonal influence of adipokines on BMF.

Table : Age-adjusted means by BMF (%) quartiles

	Q1 N=38	Q2 N=37	Q3 N=37	Q4 N=37	P for trend

### Enhanced adipo/lipogenic potential of human adipose tissue stem cells in obesity

S. Perrini<sup>1</sup>, P. Nigro<sup>1</sup>, A. Cignarelli<sup>1</sup>, M. Barbaro<sup>1</sup>, R. Ficarella<sup>1</sup>, A. Peschechera<sup>1</sup>, M. De Fazio<sup>2</sup>, F. Puglisi<sup>2</sup>, A. Natalicchio<sup>1</sup>, L. Laviola<sup>1</sup>, F. Giorgino<sup>1</sup>;

<sup>1</sup>Endocrinology & Metabolic Diseases, University of Bari, <sup>2</sup>General Surgery and Liver Transplantation, University of Bari, Italy.

**Background and aims:** An impaired adipo/lipogenic capacity of human adipose stem cells (ASCs) may contribute to obesity and the related metabolic abnormalities. Aim of this study was to investigate whether obesity is associated with changes in the adipogenic and/or lipogenic potential of ASCs from the subcutaneous (SC) and visceral (V) fat tissue depots.

**Materials and methods:** ASCs were isolated from SC and V fat biopsies, obtained from 8 lean (L) (BMI  $24.1 \pm 2.3$  kg/m<sup>2</sup>) and 8 obese (Ob) (BMI  $37.4 \pm 3.2$  kg/m<sup>2</sup>) subjects. Cells were differentiated in vitro with adipogenic inducers in the absence or presence of 100 nM insulin. Staining with Nile Red or Oil-Red-O was used to quantify adipocyte conversion and the lipid droplet size and number, respectively. mRNA levels of lipogenic and adipogenic genes were measured by qRT-PCR.

**Results:** No significant differences in the conversion to mature adipocytes were seen in SC-ASCs from L and Ob subjects, whereas adipogenesis was about 60% higher in V-ASCs from Ob compared to L donors. Following differentiation of both V-ASCs and SC-ASCs into mature adipocytes in the absence of insulin, there was a 70–80% higher number of lipid droplets, with no

apparent change in size, in Ob compared to L cells ( $p<0.05$ ). Similar results were obtained in the presence of insulin, and insulin-induced Akt and Erk-1/2 phosphorylation was similar in L and Ob ASCs. When the expression of 14 lipogenic and adipogenic genes was assessed in both ASCs and adipocytes from the experimental subjects, larger differences were found in V compared to SC cells ( $p<0.05$ ). Specifically, the SIRT1/2 mRNA levels were lower in Ob compared to L V-ASCs and adipocytes. A trend to an inverse relationship between SIRT1/2 mRNA expression and BMI was also found in V fat biopsies ( $R= -0.145$ ).

**Conclusion:** In conclusion, Ob ASCs, particularly from the V fat depot, exhibit lower SIRT1/2 gene expression and possess an enhanced inherent adipo/lipogenic potential, which is largely insulin-independent.

## 676

### Decreased PRDM16 gene expression in subcutaneous and visceral human adipose tissue in association with obesity

E. Esteve, J. Moreno-Navarrete, F. Ortega, M. Serrano, G. Pardo, N. Pueyo, E. Guerra, W. Ricart, J. Fernández-Real; Hospital of Girona, Spain.

**Background and aims:** Recent studies in mice have shown that Prdm16, a transcriptional modulator of thermogenic genes in brown adipose tissue, was expressed at substantial levels in subcutaneous WAT, promoting the expression of brown fat-specific genes in this fat depot. We aimed to investigate the possible role of PRDM16 in human adipose tissue, we aimed to analyze its expression in association with obesity, type 2 diabetes and insulin sensitivity.

**Materials and methods:** PRDM16 gene expression (Real Time PCR) was analyzed in two independent cohorts: in participants with different degrees of obesity (88 visceral and 83 subcutaneous adipose tissue samples) and in a second cohort of morbidly obese participants with different degrees of insulin action (measured with euglycemic clamp) (32 paired visceral and 32 subcutaneous adipose tissue samples).

**Results:** In the first cohort, PRDM16 gene expression was detected in both subcutaneous and visceral adipose tissues at similar levels. PRDM16 gene expression was significantly decreased in obese patients. In subcutaneous adipose tissue, PRDM16 gene expression was negatively associated with BMI ( $r= -0.23$ ,  $p= 0.04$ ), fasting glucose ( $r= -0.27$ ,  $p= 0.01$ ), and positively with the expression of IRS1 ( $r= 0.55$ ,  $p< 0.0001$ ) and mitochondrial genes [PGC1 $\alpha$  ( $r= 0.46$ ,  $p< 0.0001$ ) and mt-CO3 ( $r= 0.27$ ,  $p= 0.01$ )]. In visceral adipose tissue, PRDM16 gene expression was negatively associated with BMI ( $r= -0.30$ ,  $p= 0.005$ ), and positively with PPAR $\gamma$  ( $r= 0.40$ ,  $p= 0.004$ ), GLUT4 ( $r= 0.39$ ,  $p= 0.004$ ), IRS1 ( $r= 0.49$ ,  $p< 0.0001$ ), PGC1 $\alpha$  ( $r= 0.43$ ,  $p< 0.0001$ ) and mt-CO3 ( $r= 0.55$ ,  $p< 0.0001$ ). In multiple linear regression analysis, IRS1 and PGC1 $\alpha$  and mt-CO3 contributed independently to PRDM16 gene expression after controlling for BMI in both visceral and subcutaneous adipose tissues. In the second cohort (morbidly obese patients), PRDM16 was not associated with insulin sensitivity. The correlations with GLUT4, IRS1, PGC1 $\alpha$  and mt-CO3 were replicated. Interestingly PRDM16 in visceral adipose tissue was significantly and negatively associated with glycated hemoglobin.

**Conclusion:** The strong association among PRDM16, mitochondrial genes and IRS1 suggests that PRDM16 is a potential marker of brown-like adipose tissue in human fat similar to mouse fat. In this sense, brown-like characteristics of adipose tissue decrease with obesity.

## 677

### Visualisation of brown adipose tissue in humans with <sup>123</sup>I-metaiodobenzylguanidine SPECT-CT and <sup>18</sup>F-fluorodeoxyglucose PET-CT

W.M. Admiraal<sup>1</sup>, H.J. Verberne<sup>2</sup>, L. Bähler<sup>1</sup>, J.B.L. Hoekstra<sup>1</sup>, F. Holleman<sup>1</sup>; <sup>1</sup>Internal Medicine, Amsterdam, <sup>2</sup>Nuclear Medicine, Academic Medical Centre, Amsterdam, Netherlands.

**Background and aims:** Given its high capacity to burn excess energy, brown adipose tissue (BAT) has become a focus of research in the hope that activation of BAT may prove to be a new target to fight obesity. However, knowledge of mechanisms regulating BAT activity is only slowly progressing. For research purpose in humans, BAT is visualized with an <sup>18</sup>F-fluoro deoxyglucose (FDG) positron emission tomography (PET) computed tomography (CT). Results from studies performed in animals show that thermogenesis

in BAT is influenced by the sympathetic nervous system. In nuclear medicine,  $^{123}\text{I}$ -metaiodobenzylguanidine (MIBG), a non-functional noradrenalin analog, is used for scintigraphic assessment of neuroendocrine tumors and cardiac sympathetic activity. Therefore, given the strong sympathetic innervation of BAT, MIBG scintigraphy has been used to localize BAT in rats. In humans,  $\beta$ -adrenergic antagonists eliminate glucose uptake into BAT, suggesting that, also in man, thermogenesis is under  $\beta$ -adrenergic control. The aim of this study was to determine whether MIBG single photon emission CT (SPECT-CT), as a measure of sympathetic stimulation, and FDG PET-CT identify the same anatomical locations as BAT in adult humans. Furthermore, we investigated whether the magnitude of BAT activity measured by these two techniques correlated.

**Materials and methods:** We studied 10 lean (BMI 18–24), healthy, Caucasian males, 18–32 years old. All underwent MIBG SPECT-CT and FDG PET-CT within a 2-week interval and in random order. On both occasions, the subjects were exposed to mild cold ( $17^\circ\text{C}$ ) for the duration of 2 hours after an overnight fast. After 1 hour of cold exposure, FDG or MIBG was administered intravenously. MIBG imaging was performed 24 hours after administration, whereas the FDG PET-CT was performed 1 hour after administration. Activity of BAT was defined as maximum standard uptake value ( $\text{SUV}_{\text{max}}$ ) of FDG or as semi-quantitative uptake of MIBG in the same regions of interest. These anatomical regions of interest were cervical, supraclavicular, and superior mediastinal depots. A maximal standard uptake value ( $\text{SUV}_{\text{max}}$ ) of FDG  $\geq 2.0$  g/ml was considered to indicate BAT. Using the MIBG SPECT images, semi-quantitative uptake of MIBG in BAT was calculated as the maximum count in the anatomical volumes of interest divided by the mean count per voxel in a reference region (i.e. the lung). The correlation between semi-quantitative uptake of MIBG and  $\text{SUV}_{\text{max}}$  of FDG was determined with a Pearson correlation coefficient.

**Results:** FDG uptake in BAT was visually observed in 8 out of 10 subjects, whereas MIBG uptake in BAT was observed in 7 out of 10 subjects. All subjects that showed MIBG uptake in BAT, also showed FDG uptake in BAT. Both  $\text{SUV}_{\text{max}}$  of FDG and semi quantitative uptake value of MIBG were normally distributed. A strong, positive correlation was found between the  $\text{SUV}_{\text{max}}$  of FDG and the semi-quantitative uptake of MIBG ( $r=0.65$ ,  $p=0.04$ ).

**Conclusion:** MIBG SPECT-CT, as a marker of sympathetic activity, and FDG PET-CT, as a marker of metabolic activity, identify the same anatomical regions as active BAT. Moreover, the correlation between these two techniques is strongly positive. These findings underscore that sympathetic activity is a principal driving force for BAT activity in humans.

## 678

### Macrophage infiltration and BAT distribution in adipose tissue of children

D. Rockstroh<sup>1</sup>, I. Wagner<sup>1</sup>, K. Landgraf<sup>1</sup>, R. Tauscher<sup>1</sup>, J. Gesing<sup>1</sup>, S. Weise<sup>1</sup>, M. Blüher<sup>2</sup>, W. Kiess<sup>1</sup>, H. Till<sup>3</sup>, M. Wojan<sup>4</sup>, A. Körner<sup>1</sup>;

<sup>1</sup>University Hospital for Children and Adolescents, <sup>2</sup>University Hospital for Endocrinology and Nephrology, <sup>3</sup>University Hospital for Pediatric Surgery,

<sup>4</sup>University Hospital for Orthopaedic Surgery, Leipzig, Germany.

**Background and aims:** The role of adipose tissue in the development of obesity in children has not been sufficiently investigated. In adults it has recently been shown that obesity is accompanied by an increased infiltration of macrophages. Compared to adults, children are hypothesized to have considerably more brown adipose tissue (BAT), which decreases within the first years of life. In this study we aimed to characterize the infiltration of macrophages in adipose tissue and the distribution of BAT in children.

**Materials and methods:** We analyzed 150 adipose tissue samples of lean ( $n=100$ ; mean age= 7; range= 0–20) and obese ( $n= 50$ ; mean age= 11; range= 0–18) children for macrophage infiltration and BAT distribution.

**Results:** Immunohistochemical analyses of the macrophage-specific marker CD68 indicated a positive correlation of macrophage infiltration with BMI-SDS and adipocyte size in subcutaneous depots. We detected crown-like structures in 40% of the overweight/obese, but only in 5% of the lean children. Altogether, 12 of the 150 tissue samples presented a positive UCP1 staining, which corresponded with a significantly increased *UCP1 mRNA* expression compared to WAT. Exclusively lean children aged 0–10 showed prevalence for BAT. Morphometrically, brown adipocytes of lean children were significantly smaller ( $1477\pm346\mu\text{m}^2$ ) than white adipocytes of lean ( $4316\pm254\mu\text{m}^2$ ) and overweight/obese children ( $6251\pm313\mu\text{m}^2$ ); ( $P<0.001$ ).

**Conclusion:** We show that an increased macrophage infiltration into adipose tissue occurs already in obese children. In addition, we present evidence that BAT is present in subcutaneous adipose tissue of lean children.

## PS 049 Secreted proteins and organ cross-talk

### 679

#### Adipokine profiles discriminate different obesity mouse models

S. Hartwig<sup>1</sup>, B. Knebel<sup>1</sup>, H.-D. Dicken<sup>2</sup>, J. Kotzka<sup>1</sup>, S. Lehr<sup>1</sup>;

<sup>1</sup>Institute for Clinical Biochemistry and Pathobiochemistry, <sup>2</sup>National Diabetes Information Center, German Diabetes Center, Düsseldorf, Germany.

**Background and aims:** The group of adipokines comprises hundreds of biological active proteins and peptides released from adipose tissue. Alteration of those complex protein signatures are suggested to play a crucial role within pathophysiology of multifactorial, metabolic diseases. Our previous proteomic profiling studies uncovered the complex nature of the adipokine and identified several novel adipokines. To make the data available, we build up a database. Next to this, we started advanced investigation of adipokine profiles of lean and obese mouse models using a combined transcriptome and proteome analysis approach in order to identify potential biomarker candidates.

**Material and methods:** Explants from visceral fat depots derived from different mouse models, i.e. C57Bl6, dbdb and alb-SREBP-1a, were investigated. The dbdb mice represent the obese model induced by hyperphagia, whereas alb-SREBP-1a increases adipose tissue by elevated *de novo* lipid synthesis. At RNA level the different transcriptomes were investigated by Affymetrix-Array and RT-PCR and the secretome profiling at protein level were done by Cytokine-Arrays and the 2D-DIGE technology coupled with mass spectrometry.

**Results:** We have generated a tissue specific secretome database, labeled *Diabetesityprot* ([www.diabetesityprot.org](http://www.diabetesityprot.org)). With its functionality it is now possible to perform a target or a global search. Based on our published adipokine list of 250 annotated proteins we could confirm the expression of adipokine pattern by transcriptome data ( $>10.000$  transcripts) achieved from viscera fat depots of our mouse models. 94% of proposed adipokines were found to be present in the investigated models. Comparison analysis of the lean control with the obese mouse models identified 24 adipokines to be differentially expressed. Alpha-1-Antitrypsin (SERPINA1) a novel adipokine described to be decreased in plasma of type 2-diabetics solely could be detected in the non obese mice. Analyzing adipose tissue secretomes with cytokine arrays revealed a dramatically difference between the both obese models, e.g. IL6 was significantly elevated in dbdb mice whereas the level in alb-SREBP-1a mice was significantly low. In addition to that, 2D-DIGE secretome pattern analysis allows discriminating the two models of obesity in 50 protein spots.

**Conclusion:** The parallel utilization of transcriptome and proteome approaches and combination with systematic analysis of databases identifies differences in secretion profiles of mice displaying different characteristics of obesity. This may pave the road to identify and validate novel biomarker candidates being involved in the pathogenesis of insulin resistance and type-2-diabetes.

## 680

#### Vaspin is related to eating behaviour in humans

J. Breitfeld<sup>1</sup>, D. Schleinitz<sup>1</sup>, A. Tönjes<sup>1,2</sup>, B. Enigk<sup>1</sup>, M. Prellberg<sup>1</sup>, M. Stumvoll<sup>1</sup>, M. Blüher<sup>1</sup>, P. Kovacs<sup>1</sup>, Y. Böttcher<sup>2</sup>;

<sup>1</sup>Department of Medicine, University of Leipzig, <sup>2</sup>IFB Adiposity Diseases, University of Leipzig, Germany.

**Background and aims:** Vaspin (visceral adipose tissue derived serin protease inhibitor, serpinA12) is a novel adipokine, which might provide a link between insulin resistance and obesity. Vaspin follows a meal-related diurnal variation in humans and its intracerebroventricular administration in db/db mice leads to reduced food intake and sustained significant improvement in glucose concentrations, thus suggesting a role in the regulation of food intake. Here, we investigated the relationship between vaspin and eating behaviour in humans by analysing the correlations between serum vaspin levels, eating behaviour and genetic variants in the vaspin gene.

**Materials and methods:** We assessed eating behaviour by using the three-factor eating questionnaire in 618 Sorbian subjects from Germany. Serum vaspin levels were measured by ELISA. We performed correlation analyses

between eating behaviour and serum vaspin as well as association analyses with genetic variants.

**Results:** We found positive correlations between serum vaspin concentrations and factors measuring restraint ( $P=0.006$ ), disinhibition ( $P=0.004$ ) and hunger ( $P=0.01$ ). These data have been independently supported by genetic association analyses in which two single nucleotide polymorphisms (rs2236242, rs3736803) were significantly associated with both serum vaspin ( $P<10^{-8}$ ) and measures of eating behaviour ( $P<0.05$ ; all in regression analyses adjusted for age, sex and BMI in additive mode of inheritance).

**Conclusion:** Correlations between serum vaspin and eating behaviour along with associations of genetic variants with both vaspin concentrations and with eating behaviour suggest the role of vaspin in the regulation of eating behaviour.

### The role of visfatin and retinol binding protein 4 in glycaemic and insulinaemic status of IGT

I. Khan<sup>1</sup>, F. Kabir<sup>2,3</sup>, F.A. Jahan<sup>2</sup>, M.O. Faruque<sup>2</sup>, Z. Hassan<sup>1</sup>, L. Ali<sup>2,4</sup>;

<sup>1</sup>Dept of Physiology and Molecular Biology, BIRDEM, <sup>2</sup>Dept of Biochemistry and Cell Biology, BIRDEM, <sup>3</sup>Dept of Biochemistry, Green Life Medical College, <sup>4</sup>Dept of Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh.

**Background and aims:** Visfatin and retinol binding protein 4 (RBP4) have been reported to be associated with insulin resistance in T2DM subjects. However, their causal association in the development of T2DM is still unclear. Since, impaired glucose tolerance (IGT) is one of the intermediate stages of natural history of T2DM, we studied these adipocytokines in relation with glycemic and insulinemic status of a group of IGT.

**Subjects and methods:** Fifty eight IGT subjects were recruited purposively and 52 age-, BMI- and body fat mass (BFM)- matched healthy subjects served as control [Control vs IGT: Age (Yrs),  $42\pm5$  vs  $42\pm6$ ; BMI ( $\text{Kg}/\text{m}^2$ ),  $24.5\pm4.1$  vs  $25.5\pm4.7$ ; BFM (%),  $28.2\pm6.2$  vs  $29.3\pm7.5$ ]. Anthropometrics and total body fat mass were determined following standard procedure. Glucose and lipids were measured by standard biochemical method. Insulin, visfatin and RBP4 were estimated by using enzyme linked immunosorbent assay (ELISA). Insulin secretory capacity (HOMA%B) and insulin sensitivity (HOMA%S) were determined by homeostasis model assessment (HOMA) using HOMA-Sigma software. Data were analyzed by appropriate univariate as well as multivariate tools.

**Results:** Waist to hip ratio (WHR), blood pressures and lipids did not show statistical difference between groups except triglyceride (TG) which was found significantly higher in the IGT group compared to Controls ( $p<0.001$ ). Fasting insulin ( $\mu\text{U}/\text{ml}$ ) in the IGT group was significantly higher compared to the Controls ( $p=0.001$ ). HOMA%S (Control:  $81.9\pm18$ , IGT:  $66.5\pm18$ ) was significantly lower in the IGT compared to the Controls ( $p<0.001$  respectively). However, HOMA%B did not show any difference between the groups. Mean fasting visfatin ( $\text{ng}/\text{ml}$ ) was (Control:  $2.8\pm2.5$ , IGT:  $5.2\pm4.3$ ) was significantly higher compared to the Controls ( $p=0.004$ ). Fasting RBP4 ( $\mu\text{g}/\text{ml}$ ) (Control:  $30.4\pm6.1$ , IGT:  $36.4\pm8.6$ ) was also significantly higher in IGT group compared to the Controls ( $p<0.001$ ). Even after adjusting the effect of age, BMI, WHR, BFM and TG in binary logistic regression both Visfatin ( $p=0.017$ ) and RBP4 ( $p=0.004$ ) showed significant association with IGT group. In both bivariate correlation analysis and multiple linear regression analyses (after adjusting the effect of age, BMI, WHR, BFM and TG) both Visfatin and RBP4 showed significant positive association with postprandial glucose and fasting insulin, and significant negative association with HOMA%S (for all  $p<0.05$ ). Moreover, visfatin and RBP4 found to be correlated with each other in bivariate ( $p=0.027$ ) and multivariate (age, BMI, WHR and BFM adjusted) ( $p=0.036$ ).

**Conclusion:** Visfatin and RBP4 are associated with impaired postprandial glucose disposal in IGT subject and their role in insulin resistance may be interlinked.

### Expression of the complement system is upregulated in subcutaneous adipocytes from non-obese hypertriglyceridaemic subjects and is associated with local insulin resistance

M.M.J. van Greevenbroek<sup>1</sup>, S. Ghosh<sup>2</sup>, C.J.H. van der Kallen<sup>1</sup>, M.C.G. Brouwers<sup>1</sup>, C.G. Schalkwijk<sup>1</sup>, C.D.A. Stehouwer<sup>1</sup>;

<sup>1</sup>CARIM school for cardiovascular diseases / Department of Internal Medicine, Maastricht University, Maastricht, Netherlands, <sup>2</sup>North Carolina Central University, Durham, USA.

**Background and aims:** Dysfunctional adipose tissue plays an important role in the etiology of a large number of cardiometabolic disorders (such as dyslipidaemia, the metabolic syndrome and type 2 diabetes), independent of the presence of overt obesity. However, the molecular mechanisms underlying adipocyte dysfunction, especially in metabolically stressed non-obese subjects, are incompletely understood. A metabolic disorder involving adipose tissue dysfunction in the absence of pronounced obesity is familial combined hyperlipidaemia (FCHL). In the current investigations, FCHL served as a model of familial insulin resistance in the presence of dyslipidaemia. Our aim was to identify differentially expressed pathways in human adipocytes isolated from healthy controls and dyslipidemic patients, using transcriptome analyses.

**Materials and methods:** Whole genome expression profiling on Affymetrix GeneChip<sup>®</sup> Human Genome U133 Plus 2.0 arrays was conducted on RNA of isolated subcutaneous adipocyte fractions (free of stromal vascular cells) from 13 marginally overweight FCHL subjects (body mass index (BMI)  $26.6 \pm 2.4 \text{ kg}/\text{m}^2$ ) and 8 unrelated controls of comparable body sizes ( $25.2 \pm 3.8 \text{ kg}/\text{m}^2$ ,  $p=0.298$ ).

**Results:** Gene set enrichment and co-expression network analysis identified the complement system and its regulators as one of the top upregulated pathways in FCHL ( $\text{FDR}<1 \times 10^{-30}$ ). Complement gene expression was associated with plasma triglycerides and waist circumference, and this association was independent of age and sex. Moreover, expression of several complement genes of the classical, the alternative and the terminal pathway was inversely associated with the expression of IRS-1 in the adipocytes (Pearson's correlation coefficient ( $r$ ) ranging from  $-0.45$  to  $-0.76$ ,  $p=0.05$  to  $<0.001$ ). Hypertriglyceridaemia per se was most likely not the immediate driver of complement pathway upregulation since, in a separate intervention study of 12 FCHL subjects (8 weeks treatment 40 mg/day atorvastatin monotherapy), a 40% reduction in triglycerides did not affect complement expression in adipocytes isolated before and after the intervention.

**Conclusion:** These findings point to an upregulation of complement related transcriptome in subcutaneous adipocytes under metabolically stressed conditions, even in the absence of overt obesity. Such upregulation may subsequently influence downstream processes including macrophage infiltration into adipose tissue, insulin resistance, adipocyte apoptosis and cardiovascular risk.

## 683

### Fetuin-A influences vascular cell growth and production of proinflammatory and angiogenic proteins by human perivascular fat cells

D.I. Siegel-Axel<sup>1</sup>, K. Rittig<sup>1</sup>, N. Stefan<sup>1</sup>, J.H. Dolderer<sup>2</sup>, H.-E. Schaller<sup>2</sup>, U.A. Stock<sup>3</sup>, H.-U. Haering<sup>1,4</sup>;

<sup>1</sup>Department of Internal Medicine, Medical Clinic IV, Division of Endocrinology, Diabetology, Angiology, Nephrology and Clinical Chemistry, University Tuebingen, <sup>2</sup>Department of Plastic, Hand and Reconstructive Surgery, BG-Trauma-Center, University Tuebingen, <sup>3</sup>Department of Thoracic, Cardiac and Vascular Surgery, University Tuebingen, <sup>4</sup>Institute for Diabetes Research and Metabolic Diseases Helmholtz Center Munich University of Tuebingen (Paul Langerhans Institute Tuebingen), Partner in the German Center for Diabetes Research, Germany.

**Background and aims:** Fetuin-A or alpha-2-HS-glycoprotein, a member of the superfamily of cystatins, is produced by the fatty liver. Fetuin-A is involved in insulin resistance and diabetes mellitus, in bone metabolism, central nervous system, neurodegenerative diseases but maybe also in the cardiovascular system. Fetuin-A binds insulin receptors in muscle and fat cells, inhibits adiponectin expression and increases TNF $\alpha$  expression in human subcutaneous adipocytes. Recently, we found that perivascular fat cells (PVFC) have a higher angiogenic potential than other fat cell types. Aim of this study was to examine if fetuin-A influences the expression and secretion

of pro-inflammatory and angiogenic proteins by PVFC, and the growth of vascular smooth muscle cells (SMC) and endothelial cells (EC).

**Materials and methods:** PVFC, EC and SMC were isolated from human specimens of arm arteries from patients of the BG Trauma Center and the Department of Thoracic, Cardiac and Vascular Surgery. These cells were characterized by FACS methods and cocultured in transwell systems. In one half of the cultures human fetuin-A was added in doses between 300–600 µg/ml. After 6, 24, 48, and 72 h, supernatants were collected and cells were lysed for mRNA extraction. For the quantification of the release of pro-inflammatory and angiogenic proteins, the luminex technology was used and for mRNA expression realtime PCR. Furthermore, a specific ELISA against HGF in mono- and cocultures was performed. Finally, BrDU-ELISA and WST-assays were used to analyse growth and viability of EC and SMC under the influence of fetuin-A.

**Results:** After 6 h, but predominantly after 24–72 h, PVFC expressed and secreted the angiogenic factors PAI-1, IL-6, IL-8, bFGF, PDGF-BB, MCP-1, VEGF, PlGF and HGF. This was stimulated by the cocultivation with vascular cells. IL-8 and PlGF increased even up to 10-fold compared to monocultures. Fetuin-A inhibited the IL-8 production of PVFC, whereas the secretion of VEGF was stimulated. Furthermore, the release of HGF, which we could identify recently as an important angiogenic factor of perivascular fat released in serum of patients, was inhibited by fetuin-A. Finally, SMC-growth, and moderately also EC-growth, was inhibited by fetuin-A.

**Conclusion:** In human PVFC and vascular cells fetuin-A influences the expression and secretion of several proinflammatory and angiogenic factors and the growth of vascular cells. This extends previous studies of our group showing that fetuin-A induces mRNA expression of IL-6, IL1β, MCP-1 and TNF-α in subcutaneous adipocytes. Thus, fetuin-A maybe regulates interactions of angiogenic and proinflammatory factors of fat cells and vascular cells. This might be important for neovascularization of advanced atherosclerotic plaques.

*Supported by: BMBF to the German Center for Diabetes Research (DZD) and REGINA 01KQ0902F*

immune and inflammatory responses, chemotaxis, cell growth and apoptosis were significantly over-represented in CAF rats. Real-time PCR confirmed changes for most statistically relevant genes. Interestingly, genes involved in inflammatory response were down-regulated in islets of CAF rats. Metabolites involved in glycolysis, lipidic and aminoacids metabolism were significantly changed in CM from CAF rats. Decreased glucose consumption and lactate secretion and increased glutamine consumption and α-ketoglutarate, malate and oleic acid secretion in CM from CAF rats suggest decreased glycolysis and enhanced TCA anaplerosis. Interestingly, nicotinamide was significantly increased in CM from CAF rats, which may have a protective role on diet induced islet inflammation. The generated functional networks show that possible interrelations between genes and metabolites obtained in this study are involved in inflammatory response, cell-cell signalling, cell death and proliferation and lipid metabolism.

**Conclusion:** Preliminary meta-analysis of combined networks shows interesting interplay between genes and metabolites, supporting the hypothesis of a cross-talk between pWAT and beta-cells.

### Integration of transcriptomics and metabolomics data to unravel the cross-talk between adipose tissue and beta cells during evolution of obesity

R. Malpique<sup>1,2</sup>, H. Figueiredo<sup>1,2</sup>, M. Vinaixa<sup>3,2</sup>, S. Rebuffat<sup>1,2</sup>, S.G. Kalko<sup>4</sup>, X. Correig<sup>3,2</sup>, R. Gomis<sup>1,2</sup>

<sup>1</sup>Diabetes and Obesity, IDIBAPS - Hospital Clínic, Barcelona, <sup>2</sup>CIBERDEM, Barcelona, <sup>3</sup>Metabolomics Platform, IISPV - Universitat Rovira i Virgili, Tarragona, <sup>4</sup>Bioinformatics Unit, IDIBAPS - Hospital Clínic, Barcelona, Spain.

**Background and aims:** During evolution of obesity, an increase in beta cell mass occurs to cope with the raise in insulin demand, which is essential to avoid the onset of hyperglycemia. Changes in the adipokine secretion profile of visceral-pancreatic white adipose tissue (pWAT) due to diet-induced obesity have been shown to increase beta cell replication, suggesting that a cross-talk between pWAT and beta cells may play a role in regulating beta cell plasticity. We aimed to elucidate the molecular mechanisms involved in this cross-talk by investigating changes on pWAT gene expression and metabolite secretion due to diet-induced obesity and correlate them with changes on the transcription profile of beta-cells.

**Materials and methods:** Male Wistar rats were exposed to a 30 days high caloric cafeteria (CAF) diet or standard chow diet (n=6/group). The animals were sacrificed and pWAT and pancreatic islets were collected. Conditioned medium (CM) was obtained from pWAT by culturing in serum-free medium for 24 hours. A comparative CM analysis was performed using multiplatform untargeted metabolomics (1H-NMR, GC/MS and HPLC/MS). Transcription profiles of both tissues were analyzed using Affymetrix Rat 230.2 whole genome arrays. Statistical analyses of metabolomics and transcriptomics data were performed using Mann-Witney (p<0.05) and RankProd methods (FDR 0.01), respectively. Analysis of functional over-representation was performed according to the GO-BP database. The Ingenuity Systems Pathway Analysis software was used for cross-platform integration.

**Results:** Microarray analysis revealed the up-regulation of 45 genes in pWAT of CAF rats, whereas down-regulation of 108 genes and up-regulation of 31 genes were found for islets of CAF rats. The functional terms related to the positive regulation of immune and inflammatory responses, hormone stimulus and fatty acid metabolism were significantly over-represented in pWAT of CAF rats. In islets, functional terms corresponding to the regulation of

### Free fatty acid receptors (FFAR1) mediate effects of conjugated linoleic acid in brain

T. Sartorius<sup>1,2</sup>, A. Peter<sup>1</sup>, C. Weigert<sup>1</sup>, A.M. Hennige<sup>1</sup>, E. Schleicher<sup>1</sup>, E. Kostenis<sup>3</sup>, H.-U. Haering<sup>1</sup>, S. Ullrich<sup>1</sup>;

<sup>1</sup>Division of Endocrinology, Diabetology, Vascular Disease, Nephrology and Clinical Chemistry, University of Tuebingen, <sup>2</sup>Institute for Diabetes Research and Metabolic Diseases (IDM) of the Helmholtz Center Munich at the University of Tuebingen, <sup>3</sup>University of Bonn, Germany.

**Background and aims:** Conjugated linoleic acids (CLAs) are attractive nutritional additives since they influence body fat distribution and increase muscle mass. However, the intake of CLAs results in adverse effects such as worsening of peripheral insulin resistance and increasing the risk of developing diabetes. We have previously found that CLAs, both the cis-9, trans-11-, and the trans-10, cis-12-CLA isomer, act through the activation of the free fatty acid receptor 1 (FFAR1 former GPR40) in insulin secreting cells. FFAR1 is also expressed in brain and regulates certain neurological functions. The aim of the present study was to analyse whether orally administered CLAs affect brain function and to decipher the role of FFAR1.

**Materials and methods:** FFAR1 null mice and their WT littermates at the age of 6–10 weeks were orally administered by gavage with CLAs or sunflower oil (control) for 30 days. The impact on glucose homeostasis was evaluated by intraperitoneal GTT and brain fatty acid composition by gas chromatography. Radiotelemetry recordings were performed to assess brain activity and locomotor behaviour after an acute intracerebroventricular (icv) application of the CLA isomers to achieve a final concentration of 100 µmol/l.

**Results:** In brain of WT mice, the concentration of CLA significantly increased 2.3-fold after CLAs feeding ( $P < 0.005$ ,  $n = 4$ ). The respective concentrations in FFAR1 null mice were not significantly different to WT. However, a prominent role of the FFAR1 in brain function could be detected after an acute administration of the two CLA isomers. Acutely administered 10/12 CLA isomer in the cerebrospinal fluid of WT mice stimulated brain activity in the low frequency band (delta) more efficiently than the 9/11 CLA isomer (delta: by  $27.1 \pm 7.1\%$  (9/11 CLA) vs.  $51.9 \pm 8.3\%$  (10/12 CLA);  $P < 0.05$ ;  $n = 4$ /group). In FFAR1 null mice no significant difference was found between the two CLA isomers (delta:  $23.7 \pm 4.9\%$  (9/11 CLA) vs.  $24.7 \pm 5.4\%$  (10/12 CLA);  $n = 5$ /group). Interestingly, locomotor activity was reduced after acute icv administration of 9/11 CLA isomer in WT but not in FFAR1 null mice (WT:  $52.5 \pm 5.6\%$  vs. vehicle  $100 \pm 8.4\%$ ;  $P < 0.001$ ). In addition, insulin resistance provoked by chronic CLAs feeding was also not dependent on FFAR1 expression. **Conclusion:** Orally ingested CLAs accumulate in brain tissue and affect brain activity and locomotion. These effects are at least partially mediated by FFAR1. Our results suggest that orally ingested CLAs not only exert adverse effects in the periphery but also in the brain.

### Regulation of AMP-activated protein kinase alpha 2 expression by a fasting/ghrelin-induced transcription factor, AF5q31, in the hypothalamic neurons

T. Komori<sup>1</sup>, A. Doi<sup>2</sup>, T. Nosaka<sup>3</sup>, H. Furuta<sup>2</sup>, T. Akamizu<sup>2</sup>, T. Kitamura<sup>4</sup>, E. Senba<sup>1</sup>, Y. Morikawa<sup>1</sup>;

<sup>1</sup>Anatomy and Neurobiology, Wakayama Medical University, <sup>2</sup>The First Department of Medicine, Wakayama Medical University, <sup>3</sup>Department of Microbiology, Mie University Graduate School of Medicine, <sup>4</sup>Division of Cellular Therapy, Advanced Clinical Research Center, The Institute of Medical Science, The University of Tokyo, Japan.

**Background and aims:** In the hypothalamus, fasting induces a member of the AF4 family of transcription factors, AF5q31, originally identified as a fusion partner of the MLL (mixed-lineage leukemia) gene in infant acute lymphoblastic leukemia. However, the roles of AF5q31 in the hypothalamus remain unclear. In the present study, we reported a novel functional role of AF5q31 in the hypothalamic neurons.

**Materials and methods:** The effects of fasting and ghrelin on the expression of AF5q31 were examined in mice. We used a hypothalamic neuronal cell

line, GT1-7 cells, to investigate the direct effect of ghrelin on the expression of AF5q31 and the roles of AF5q31 on the expression of various AMP-activated protein kinase (AMPK) subunit isoforms.

**Results:** The expression of AF5q31 was increased in the neurons of the arcuate nucleus and ventromedial hypothalamic nucleus (VMH) of fasted mice compared to those of mice fed ad libitum. AF5q31 expression was exclusively observed in growth hormone secretagogue-receptor (GHS-R)-expressing neurons during fasting. The intraperitoneal injection of ghrelin induced the expression of AF5q31 in the GHS-R-positive neurons of the arcuate nucleus and VMH. To examine the direct effect of ghrelin on the expression of AF5q31, we used the hypothalamic cell line GT1-7, in which GHS-R is expressed. In GT1-7 cells, ghrelin markedly induced the expression of AF5q31 in a time- and dose-dependent manner, suggesting that ghrelin directly induce the expression of AF5q31 in the hypothalamus during fasting. Following the induction of AF5q31 expression by ghrelin, the expression of AMPKα and phosphorylation of acetyl CoA carboxylase α (ACCα), a downstream target of AMPK, were increased in GT1-7 cells. These results raise the possibility that AF5q31 regulates the AMPK signaling pathway through the regulation of AMPKα expression. To test this possibility, we transfected full-length AF5q31 in GT1-7 cells. The overexpression of AF5q31 in GT1-7 cells specifically induced the expression of the AMPKα2 subunit, but failed to induce other AMPK subunits and AMPK upstream kinases. In addition, the promoter activity of AMPKα2 gene increased by the addition of AF5q31, suggesting that AF5q31 regulates the transcription of AMPKα2 gene.

**Conclusion:** AF5q31 induced by fasting and ghrelin may modulate AMPK signaling by inducing the expression of AMPKα2 in the hypothalamus.

### Insulin detemir reduces activity in reward-related brain regions in response to visual food stimuli in type 1 diabetes: possible explanation for its weight-sparing effect?

L.W. van Golen<sup>1</sup>, D.J. Veltman<sup>2</sup>, R.G. Ijzerman<sup>1</sup>, J.B. Deijen<sup>3</sup>, M.L. Drent<sup>1</sup>, F. Barkhof<sup>4</sup>, M. Diamant<sup>1</sup>;

<sup>1</sup>Diabetes Center/ Department of Internal Medicine, <sup>2</sup>Department of Psychiatry, <sup>3</sup>Department of Clinical Neuropsychology, <sup>4</sup>Department of Radiology, VU University Medical Center, Amsterdam, Netherlands.

**Background and aims:** Insulin detemir therapy is associated with less weight gain than other insulin therapies like NPH insulin, but the underlying mechanisms have not been elucidated. Functional magnetic resonance imaging (fMRI) studies have shown an increased activity in reward-related brain regions when obese subjects are confronted with visual food stimuli. Since insulin enters the brain and acts as a satiety hormone, we hypothesised that treatment with insulin detemir would result in decreased activity in these reward-related brain regions in patients with type 1 diabetes (T1DM) when viewing food pictures compared to treatment with NPH insulin.

**Materials and methods:** Thirty-two T1DM males (mean ± SD; age  $36.3 \pm 9.4$  years, body weight  $83.9 \pm 13.8$  kg, BMI  $25.3 \pm 3.2$  kg·m<sup>-2</sup>, diabetes duration  $13.0 \pm 8.6$  years, HbA1c  $7.3 \pm 0.6\%$ ) were included in a randomised cross-over study. Patients were treated with a basal bolus regimen for 2 periods of 12 weeks, starting with either insulin detemir or NPH insulin, in combination with insulin aspart. After each treatment period, all patients had an fMRI early in the morning in the fasted state. During the scan, pictures were shown of either food or non-food items and patients had to perform a memory encoding task. Hunger ratings before and after scanning were scored on a Likert scale. Eating behaviour was scored using the DEBQ. Imaging data were analysed in SPM8 and peak level maps were obtained with a threshold at  $< 0.05$ .

**Results:** After 12 weeks, daily insulin doses and HbA1c were similar in both treatment groups. Insulin detemir decreased body weight by 0.8 kg, whereas NPH insulin increased weight by 0.5 kg (between-group difference  $p = 0.02$ ). During fMRI, mean glucose levels were  $8.8 \pm 3.6$  mmol/l in the detemir group versus  $10.4 \pm 4.0$  mmol/l in the NPH insulin group ( $p = 0.046$ ); no differences between groups were observed in hunger ratings or eating behaviour. Patients treated with NPH insulin showed increased brain activity in the bilateral insula when watching food pictures versus non-food pictures compared to patients treated with insulin detemir ( $p < 0.04$  FWE); these differences between groups were not affected by adjustment for glucose levels.

**Conclusion:** Treatment with insulin detemir resulted in reduced activation in reward-related brain regions in response to visual food stimuli compared to NPH insulin treatment in T1DM patients, which was paralleled by a decrease in body weight after 12 weeks of treatment. These results lend support to the

hypothesis that insulin detemir results in less weight gain by enhancing satiety signals on the brain.

### The prevalence of impaired glucose regulation in patients with sleep disorder and its relationship with altered HPA and HPT axis activity

J. Li<sup>1</sup>, Y. Yu<sup>1</sup>, X. Sun<sup>2</sup>;

<sup>1</sup>Endocrinology and Metabolism, <sup>2</sup>Mental Health Center, West China Hospital, West China Medical School, Sichuan University, Chengdu, China.

**Background and aims:** Sleep disorder such as early awakenings and difficulties with initiation of sleep is associated with adverse effect on glucose regulation, but few studies have examined its association with prevention of type 2 diabetes. This study was designed to evaluate the fasting glucose, tolerance glucose and the concentration of plasma insulin, assess the function of both hypothalamic-pituitary-thyroid (HPT) and hypothalamic-pituitary-adrenal (HPA) axis and to investigate the relationship of altered hypothalamic function with sleep disorder.

**Materials and methods:** From January 2010 to December 2011, 501 patients including 324 female (64.7%) and 177 male (35.32%) diagnosed with sleep disorder participated in this cross-sectional study in psychiatric outpatient department. The data of 75g glucose tolerance tests, insulin releasing test, morning (8:00) serum cortisol, TSH TT3 TT4 FT3 FT4, were collected as well as BMI and WHR to assess prevalence of IGR and function of HPA and HPT axis.

**Results:** 301 patients were diagnosed with anxiety disorder (78%) and 200 patients were diagnosed with depression (22%). The crude prevalence rates were 15.0% for diabetes, 11.6% for IGT, 15.8% for IFG, and 11.6% for IGR (IGT+IFG). The total prevalence of impaired glucose regulation in sleep disorder was 48.8%. These rates are significantly higher than the prevalence found in the general adult population. The mean cortisol level was  $463.5 \pm 178.8$  nmol/L, and the cortisol concentration at 8:00 a.m. was significantly associated with higher IGR prevalence and insulin resistance. The TSH ranged from 0.005–12.8 mU/L, median 2.76 mU/L, TSH values above 2 mU/L accounted for over 58%. FT4 ranged from 8.16–47.38 pmol/L, median 15.52 pmol/L. An increased prevalence of IGR in sleep disorders relative to the general population is highly suggested by the literature.

**Conclusion:** These results partially confirm that high level of cortisol and the increased activity of the HPT axis are associated with impaired glucose regulation. Therefore, as a pathophysiological event, abnormal activity of hypothalamic function of the sleep disorder patients could be viewed as a potential risk factor for increasing incidence of diabetes.

### MC4R genetic variants associated with fat consumption and lower visceral fat accumulation in humans

M. Gorska<sup>1</sup>, E. Adamska<sup>1,2</sup>, A. Citko<sup>1</sup>, N. Wawrusiewicz-Kurylonek<sup>1</sup>, J. Gościk<sup>3</sup>, M. Waszczeniuk<sup>2</sup>, J. Pliszka<sup>4</sup>, J. Wilk<sup>1</sup>, A. Krętowski<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Diabetology and Internal Medicine,

<sup>2</sup>Department of Dietetics and Clinical Nutrition, <sup>3</sup>Centre for Experimental

Medicine, <sup>4</sup>Department of Gynecology, Medical University, Białystok, Poland.

**Background and aims:** It is generally believed that Interaction between life-style and genetic factors play a role in the obesity development. More than 40 novel loci associated with adiposity have been recently identified. Melanocortin-4-receptor (MC4R) gene is the most common form of monogenic obesity; however, the functional effects of polymorphic variants of MC4R variants in general populations remain uncertain. The aim of our study was to analyze whether common genetic variants near the MC4R gene associated with obesity in GWAS influence diet preferences, physical activity, visceral fat accumulation and energy expenditure.

**Materials and methods:** We genotyped previously identified MC4R SNPs: rs17782313, rs633265, rs1350341, rs12970134 in 449 overweight/obese patients and 227 healthy volunteers with normal weight (289 men and 387 women), who underwent anthropometry (BMI, WHR) and body composition analysis: percent body fat, visceral (VAT) and subcutaneous abdominal adipose tissue (SAT) by multi-frequency bio-impedance method. In a subgroup of 358 subjects the 3-day diary analysis was performed and intake of

calories, carbohydrates, lipids and protein was analyzed. Moreover, in randomly selected 27 subjects carbohydrate and lipid oxidation was evaluated with indirect calorimetry during two consecutive: high-fat and high-carb meal tests. Measured genotype analysis (MGA) was used to test association between SNPs and phenotypes.

**Results:** We found the significant associations of visceral fat content and VAT/SAT ratio with the distribution of genotypes of the MC4R studied SNPs ( $p=0.003$ ). Subjects with GG genotype (rs1350341), who had the lowest visceral fat accumulation presented 2 fold higher carbohydrate oxidation rate after high-carb meal ( $p=0.043$ ) and surprisingly the highest fat consumption in 3-day diet analysis ( $p=0.015$ ).

**Conclusion:** We believe that our study may help to understand the pathways that control body mass and fat deposition in humans and provide personalized treatments and prevention strategies to fight against obesity.

**Weight gain within the first year after new onset diabetes is associated with risk of cardiovascular mortality: a cohort of 8,326 primary care patients**

J. Bodegard<sup>1</sup>, J. Sundström<sup>2</sup>, B. Svennblad<sup>3</sup>, C. Östgren<sup>4</sup>, P.M. Nilsson<sup>5</sup>, G. Johansson<sup>2</sup>;

<sup>1</sup>Medical Department, AstraZeneca, Oslo, Norway, <sup>2</sup>Uppsala University, Sweden, <sup>3</sup>Uppsala Clinical Research Center, Sweden, <sup>4</sup>Linköping University, Sweden, <sup>5</sup>Lund University, Sweden.

**Background and aims:** Increased body mass index (BMI) in diabetes patients has been suggested to be associated with higher coronary heart disease risk. We explored the association between BMI changes within the first year of new onset diabetes (NOD) and the risk of cardiovascular disease (CVD) mortality.

**Materials and methods:** A cohort of 38,960 diabetes patients with NOD, no history of previous CVD or cancer, and available BMI measurements was identified at 84 primary care centers in Sweden (1999–2009). Of these, 8,326 patients had their BMI measured at least twice, at the time of NOD and within one year after the NOD diagnosis. After the last BMI measurement, the patients were followed for up to 10 years. Morbidity- and mortality data was retrieved by linking these patients to National Cause of Death and Hospital Discharge registers. Patients were grouped according to one year BMI change after NOD: “Increase”  $\geq 1$  BMI unit increase; “Unchanged” = between +1 and -1 BMI unit change; “Decrease”  $\geq 1$  BMI unit decrease. CVD risks were estimated with Cox regression, adjusted for age, gender, baseline BMI, history of angina pectoris, education, marital status and glucose lowering drugs. CVD mortality includes sudden and unexpected death, death from stroke and myocardial infarction.

**Results:** Baseline mean age was 60.0 years (range 35–79) and mean BMI 30.2 kg/m<sup>2</sup> (range 16.7–58.5). After a median follow up time of 4.6 years (38,300 patient years), most patients, 53.4%, had an unchanged BMI, 32.2% a decrease, and 14.4% an increase. At baseline, patients with increasing BMI were younger, had lower HbA1c, triglycerides and systolic blood pressure, and were during the first year with NOD more frequently on insulin and sulfonylureas; less frequently on metformin and antihypertensives compared to the unchanged group. Patients in the increased BMI group had a 63% (95%CI 1.11–2.39) increased risk of CVD death compared to patients with unchanged BMI, see figure, and all cause death increased by 33% (95%CI 1.01–1.76). In a subgroup analysis of the 3,034 patients (36.4%) increasing their BMI  $>0$  in the first year with NOD; 100 (3.3%) died from CVD and every 1 unit BMI increase was associated with 12% increased risk of CVD death (95%CI 0.94–1.33).

**Conclusion:** Increase in body mass index during the first year after new onset diabetes is associated with increased long term risk of death due to cardiovascular disease. The study also suggests that the level of BMI increase is associated with an elevated risk of dying from cardiovascular disease and every effort should be made to minimize increase in BMI in diabetes patients.

**Endothelial dysfunction, endothelin-1 and inflammatory cytokines in patients with diabetic cardiomyopathy**

J.B. Belchina, L.K. Sokolova, N.D. Tronko, A.S. Efimov;  
Diabetology, Endocrinology and Metabolism, Kyiv, Ukraine.

**Background and aims:** The diabetic state is also associated with endothelial dysfunction as an initial manifestation of vascular abnormalities in diabetes. We are interested in the role of endothelin-1 and inflammatory cytokines in the pathogenesis of cardiomyopathy in patients with DM type1. The aim of this study was to assess echocardiographic evidence of cardiomyopathy and its association with endothelial function, inflammatory cytokines and endothelin-1 in type 1 normotensive non-proteinuric diabetic patients

**Materials and methods:** Fifty patients with type 1 DM (mean age 30.1  $\pm$  1.8 years) and 20 healthy controls (mean age 29.9  $\pm$  1.8 years) were studied. Each patient was underwent echocardiography and assessment of brachial endothelial function. Indexes of left ventricular diastolic filling were measured by Doppler-echocardiography. Endothelial function was investigated using ultrasound assessment of flow-mediated dilatation (FMD). ET-1, IL-10, IL-6, TNF- $\alpha$  were determined by ELISA. Data are presented as mean  $\pm$  SD. The results were compared using Student's paired test.

**Results:** A diagnosis of LVDD was made when at least one of the following parameters was present in the echocardiographic study: isovolumetric relaxation time (IRT)  $>100$ ms, deceleration time (DT)  $>220$  ms or early filling rate peak/late filling rate peak ratio (E/A)  $<1$ . According to these criterions 18 (36%) of the 50 diabetic patients had evidence of diastolic dysfunction as assessed by the presence of at least two abnormal variables of mitral inflow velocity. The percent change in diameter of the brachial artery in response to reactive hyperemia was significantly impaired in patients with DM compared with control subject, and this impairment was significantly more prominent in patients with diabetic cardiomyopathy than in those without diastolic dysfunction. So, the percent change in diameter of the brachial artery in response to reactive hyperemia in patients with diabetic cardiomyopathy (8.4  $\pm$  1.5%) was significantly lower than that in healthy volunteers (17.6  $\pm$  1.3%), ( $p < 0.05$ ), and in patients with DM but without cardiomyopathy (13.6  $\pm$  0.9%), ( $p < 0.05$ ). According to our data plasma level of ET-1 was extremely higher in patients with diabetic cardiomyopathy (2.67  $\pm$  0.38 fmol/ml) than that in healthy volunteers (0.12  $\pm$  0.02 fmol/ml), ( $p < 0.05$ ), and in patients with DM but without cardiomyopathy (1.33  $\pm$  0.23 fmol/ml), ( $p < 0.05$ ). Our results showed that an anti-inflammatory pattern of cytokine production is activated in patients with DM and cardiomyopathy, so anti-inflammatory cytokine IL-10 plasma level was higher in patients with diabetic cardiomyopathy (3.42  $\pm$  0.26 ng/ml) than that in healthy volunteers (0.29  $\pm$  0.05 ng/ml), ( $p < 0.05$ ), and in patients with DM but without cardiomyopathy (1.05  $\pm$  0.09 ng/ml), ( $p < 0.05$ ). Our data show that proinflammatory cytokines IL-6, TNF- $\alpha$  were higher in patients with DM and cardiomyopathy (2.22  $\pm$  0.28 ng/ml) and (1.82  $\pm$  0.19 ng/ml) compared in patients without diabetic cardiomyopathy (1.47  $\pm$  0.16 ng/ml) and (1.32  $\pm$  0.23 ng/ml) and in control subjects (0.31  $\pm$  0.09 ng/ml) and (0.58  $\pm$  0.12 ng/ml), respectively, ( $p < 0.05$ ).

**Conclusion:** Our data suggest that 1) more than one-third of young type 1 DM patients with a normal systolic ventricular function have diabetic cardiomyopathy; 2) impairment of endothelial function was significantly more prominent in patients with diabetic cardiomyopathy; 3) inflammatory cytokines might be able to play a key role in the pathogenesis of diabetic cardiomyopathy.

**Visceral but not cardiac fat is related to idiopathic dilated cardiomyopathy (DCM): a magnetic resonance study**

A. Sironi, R. Sicari, M. Gaggini, E. Buzzigoli, C. Carpeggiani, A. Gastaldelli;  
CNR Institute of Clinical Physiology, Pisa, Italy.

**Background and aims:** Excess cardiac fat, especially epicardial fat (EPI), has been related to coronary atherosclerosis and cardiac dysfunction. We have previously shown that patients with dilated cardiomyopathy (DCM) have reduced cardiac uptake/oxidation of free fatty acids (FFA) and preferential carbohydrate utilization by the heart. However, the role of EPI, if any, in DCM patients remains unsettled. Therefore, the aim of our study was to evaluate the relationship between epicardial and visceral fat with cardiac dysfunction assessed magnetic resonance (MR) in patients with DCM.

**Materials and methods:** We evaluated 99 subjects by cardiac magnetic resonance (CMR): 42 DCM patients (35/7 M/F; age 56  $\pm$  12 years, mean  $\pm$  SD) with ejection fraction  $<50\%$  (33.9  $\pm$  9.8) and angiographically normal coronary

arteries, New York Heart Association class < 3 (mean  $1.7 \pm 0.8$ ); 57 gender-matched subjects (47/10 M/F; age  $46 \pm 9$  years) with normal cardiac function. Cardiac fat, ventricular volumes, dimensions and LV function were assessed in all subjects during the MR exam and in a subset of subjects ( $n=85$ ) visceral (VF) and subcutaneous (SC) abdominal fat were also assessed by MRI.

**Results:** Patients with DCM and control subjects were matched per BMI ( $26.6 \pm 0.6$  vs.  $27.6 \pm 0.4$  kg/m<sup>2</sup>) and insulin resistance (HOMA  $3.3 \pm 0.3$  vs  $3.4 \pm 0.4$  mmol/l x mU/l) all  $p=NS$ . Total cardiac fat accumulation was similar in DCM patients and control subjects ( $2534 \pm 1092$  vs  $2589 \pm 1160$  mm<sup>2</sup>;  $p=0.81$ ). Subdivision in epicardial and extra-pericardial (ie mediastinal) fat showed no difference compared with the control group ( $854 \pm 389$  vs.  $785 \pm 334$  mm<sup>2</sup>,  $p=0.3$  and  $1747 \pm 867$  vs.  $1837 \pm 1042$  mm<sup>2</sup>,  $p=0.6$ , respectively). On the other hand visceral fat was significantly higher in CMD patients than in controls ( $1.9 \pm 0.2$  vs.  $1.3 \pm 0.1$  kg,  $p<0.01$ ) while SC fat was similar ( $2.6 \pm 0.2$  vs.  $2.6 \pm 0.2$  kg  $p=0.5$ ). In the whole data set epicardial ( $r=0.22$ ), mediastinal ( $r=0.33$ ), VF ( $r=0.36$ ) and SC ( $r=0.22$ ) fat were all positively related to HOMA (all  $p<0.05$ ). Regarding the correlation with cardiac parameters, only VF was significantly associated with increased LV mass ( $r=0.37$ ,  $p=0.001$ ), LV end systolic volume ( $r=0.33$ ,  $p=0.004$ ) and reduced EF ( $r=-0.28$ ,  $p=0.016$ ). In the logistic regression model, after accounting for BMI and gender, only visceral fat was related with CMD (OR=1.001, partial  $r=0.27$ ,  $p=0.0015$ ).

**Conclusion:** In patients with DCM, cardiac and subcutaneous abdominal fat were not increased compared to control subjects matched per BMI and insulin resistance whereas visceral fat was higher and related to the parameters of cardiac dysfunction severity.

### Polarisation of circulating monocyte-macrophages is imbalanced in type 2 diabetes owing to defects in the expression of scavenger receptors

G.P. Fadini, S. Vigili de Kreutzenberg, C. Agostini, A. Avogaro;  
Department of Medicine, University of Padova, Italy.

**Background and aims:** Type 2 diabetes (T2D) is associated with subclinical chronic inflammation, which contributes to the high cardiovascular risk. Monocyte-macrophage lineage cells exist in different states of activation. Classically activated (M1) cells are pro-inflammatory and predisposed to enter the diseased vessel wall, while alternatively activated (M2) cells patrol the vessels and provide anti-inflammatory signals. M1 and M2 cells have opposing functions in both atherosclerosis and adipose tissue inflammation. We aimed to determine whether an imbalance between M1 and M2 exists at various stages of the development of T2D.

**Methods:** We enrolled 42 normal glucose tolerant (NGT) subjects, 38 pre-diabetic subjects (either IFG or IGT or both) and 43 T2D patients. We quantified circulating M1 and M2 phenotypes using flow cytometry by characterizing cells in the monocyte morphological gate: M1 were defined as CD68+CCR2+ cells and M2 were defined as CX3CR1+CD163+/CD206+ cells. Cell counts were expressed as percentage of circulating monocytes and the M1/M2 balance as the ratio between M1 and M2 percentages.

**Results:** The 3 groups of study subjects were matched for age ( $60.7 \pm 0.8$  years old) and sex (67% males). T2D patients had higher BMI, waist circumference, systolic blood pressure and lower HDL cholesterol than NGT subjects. T2D patients also had a higher prevalence of atherosclerotic cardiovascular disease. In NGT subjects,  $30.8 \pm 3.0\%$  and  $20.2 \pm 2.7\%$  of circulating monocytes had M1 and M2 characteristics, respectively (M1/M2 balance  $1.5 \pm 0.4$ ). In pre-diabetic individuals, an increase in M1 ( $39.6 \pm 3.3\%$ ;  $p=0.05$  vs NGT) was paralleled by a slight increase in M2 ( $26.8 \pm 4.3\%$ ;  $p=0.18$  vs NGT) cells, which preserved the M1/M2 balance ( $1.5 \pm 0.3$ ). On the other hand, in T2D patients, M1 cells were non significantly increased ( $34.4 \pm 2.8\%$ ) while M2 cells were markedly reduced ( $5.8 \pm 1.7\%$ ;  $p<0.0001$  vs NGT) and the M1/M2 ratio was markedly unbalanced ( $5.9 \pm 1.0$ ). The M1/M2 ratio was directly correlated with BMI ( $r=0.19$ ;  $p=0.031$ ), waist ( $r=0.22$ ;  $p=0.014$ ) and HbA1c ( $r=0.31$ ;  $p<0.001$ ). The association between M1/M2 ratio and T2D was independent of BMI, waist, blood pressure, HDL and atherosclerotic disease. The M1/M2 imbalance in T2D was mainly attributable to a reduction in the expression of the scavenger receptors CD163 and CD206, which are critical for the clearance activity of monocyte-macrophage cells.

**Conclusion:** While in IFG/IGT subjects a surge in M1 cells is balanced by M2 cells, T2D patients show a profound imbalance in pro- versus anti-inflammatory monocytes compared to NGT subjects. This is mainly attributable to a defect in the expression of scavenger receptors that are functional to the anti-inflammatory activity of M2. These alterations, that are potentially important determinants of cardiovascular risk, may be directly related to hyperglycemia.

### THOC5-a novel gene associated with HDL-cholesterol

M. Keller<sup>1</sup>, A. Tönjes<sup>2</sup>, J. Dünnebeil<sup>3</sup>, D. Schleinitz<sup>2</sup>, Y. Böttcher<sup>1</sup>, J. Breitfeld<sup>2</sup>, N.W. Rayner<sup>4</sup>, A. Fischer-Rosinsky<sup>5</sup>, M. Koriath<sup>2</sup>, A. Pfeiffer<sup>6,5</sup>, K. Krohn<sup>3</sup>, L. Groop<sup>7</sup>, J. Spranger<sup>5</sup>, M. Stumvoll<sup>1,2</sup>, P. Kovacs<sup>3</sup>;

<sup>1</sup>IFB-Adiposity Diseases, University of Leipzig, Germany, <sup>2</sup>Department of Medicine, University of Leipzig, Germany, <sup>3</sup>Interdisciplinary Centre for Clinical Research, University of Leipzig, Germany, <sup>4</sup>Wellcome Trust Centre for Human Genetics, University of Oxford, UK, <sup>5</sup>Clinic of Endocrinology, Diabetes and Nutrition, Charité-Universitätsmedizin Berlin, Germany, <sup>6</sup>Department of Clinical Nutrition, German Institute of Human Nutrition, Nuthetal, Germany, <sup>7</sup>Department of Clinical Sciences/Diabetes and Endocrinology, Lund University, Malmö, Sweden.

**Background and aims:** Although numerous genes are known to regulate serum lipid profiles, identified variants still explain only a small proportion of expected heritability. We intended to identify further variants associated with lipid phenotypes in a self-contained population of Sorbs in Germany.

**Materials and methods:** We performed a genome wide association study (GWAS) on LDL-cholesterol (LDL), HDL-cholesterol (HDL) and triglyceride levels (TG) in 839 Sorbs. All single nucleotide polymorphisms (SNPs) with a  $P<0.01$  were taken forward to a meta-analysis including an independent Swedish cohort (Diabetes Genetics Initiative [DGI];  $n \sim 3100$ ). Novel association signals with the strongest effects were taken forward to replication studies in an additional German cohort (Berlin,  $n = 2031$ ).

**Results:** In the primary GWAS in the Sorbs we identified 14 loci associated with lipid traits with a  $P<10^{-5}$ . Moreover we could confirm significant effects for 18 previously reported loci. The combined analysis of the three study cohorts ( $n(\text{HDL}) = 6041$ ,  $n(\text{LDL}) = 5995$ ,  $n(\text{TG}) = 6087$ ) for the strongest association signals from the meta-analysis showed significant effects of the THOC5 variant rs8135828 on HDL serum concentrations ( $P=1.78 \times 10^{-7}$ ; Z-Score = 5.221). Genotyping of 4 tagging SNPs in the initial study population (Sorbs) within the THOC5 revealed 3 SNPs (rs8140060, rs4823045, rs2283860) moderately associated with HDL-cholesterol (all  $P \leq 0.05$ ).

**Conclusion:** We propose THOC5 to be a novel locus associated with serum HDL levels. Functional investigations to further support the role of THOC5 in HDL metabolism are currently ongoing.

## 695

### Weight loss and improvements in cardiometabolic outcomes with extended-release phentermine/topiramate treatment in overweight/obese subjects with type 2 diabetes

A.V. Astrup<sup>1</sup>, J.-M. Oppert<sup>2</sup>, C.A. Peterson<sup>3</sup>;

<sup>1</sup>Department of Human Nutrition, LIFE, University of Copenhagen, Frederiksberg, Denmark, <sup>2</sup>Department of Nutrition, University Pierre-et-Marie Curie, Paris, France, <sup>3</sup>Vivus, Inc., Mountain View, USA.

**Background and aims:** Treatment targets for overweight and obese patients with type 2 diabetes mellitus (T2DM) include weight loss, reduction of glycosylated haemoglobin (HbA1c) to <6.5%, and reduction of systolic blood pressure (SBP) to <130 mg/dL. Previously, CONQUER, a 56-week, randomised study of overweight/obese subjects with  $\geq 2$  weight-related comorbidities, demonstrated significant weight loss with phentermine plus extended-release topiramate (PHEN/TPM ER) compared with placebo. This post-hoc analysis assessed changes in weight, HbA1c, and SBP, and the percentage of subjects who achieved the composite goal of weight loss >10%, HbA1c <6.5%, and SBP <130 mm Hg in subjects with T2DM at baseline.

**Materials and methods:** Subjects received lifestyle intervention plus placebo, PHEN 7.5 mg/TPM ER 46 mg (7.5/46), or PHEN 15 mg/TPM ER 92 mg (15/92) and were managed to T2DM standards of care. Least-squares (LS) mean percent weight loss and changes in HbA1c and SBP were assessed at week 56 in subjects with T2DM at baseline. The proportions of subjects with T2DM at baseline who achieved the composite goal at week 56 were also evaluated.

**Results:** In total, 388 subjects had T2DM at baseline: lifestyle intervention plus placebo ( $n=157$ ), 7.5/46 ( $n=67$ ), or 15/92 ( $n=164$ ). Percent weight loss and reductions in HbA1c were significant vs placebo for all comparisons; changes in SBP were not significant vs placebo (Table). In total, 62 subjects (6 [3.8%], 9 [13.4%], and 47 [28.7%] in the placebo, 7.5/46 and 15/92 groups, respectively) achieved the composite goal. In subjects with T2DM at baseline,

there were 6 reports of hypoglycaemia: 4 in the placebo group (1 severe; 3 mild) and 1 in each of the 7.5/46 and 15/92 groups (both mild). Discontinuation due to adverse events was 8%, 9%, and 19% for placebo, 7.5/46, and 15/92, respectively, with the most common adverse events being constipation, upper respiratory tract infection, and paraesthesia.

**Conclusion:** These findings show that in obese subjects with T2DM, weight loss induced by PHEN/TPM ER is associated with improvements in HbA1c and SBP. This indicates that PHEN/TPM ER treatment may facilitate the achievement of composite treatment goals that are recommended for the management of T2DM.

Table. LS mean change in endpoints at week 56 in subjects with T2DM at baseline (ITT-LOCF)

	Placebo	7.5/46	15/92
Weight loss, %	1.9	6.8*	8.8*

## 696

### Effects of extended-release phentermine/topiramate on weight loss and blood pressure in obese subjects with type 2 diabetes mellitus

S.K. Rössner<sup>1</sup>, A.M. Sharma<sup>2</sup>, B. Troupin<sup>3</sup>, R.S. Padwal<sup>4</sup>;

<sup>1</sup>Karolinska University Hospital Huddinge, Bromma, Sweden, <sup>2</sup>Obesity Research & Management, University of Alberta, Edmonton, Canada, <sup>3</sup>Vivus, Inc., Mountain View, USA, <sup>4</sup>Department of Medicine, University of Alberta, Edmonton, Canada.

**Background and aims:** Weight loss (WL) and HbA1c control are essential in the management of type 2 diabetes mellitus (T2DM). The Edmonton Obesity Staging System (EOSS), validated against NHANES data, classifies morbidity based on degree of common weight-related comorbidities. Phentermine plus extended-release topiramate (PHEN/TPM ER) resulted in significant WL vs placebo (PBO) in a Phase 3, double-blind, 56-week study (CONQUER) of overweight/obese subjects with  $\geq 2$  weight-related comorbidities. This post-hoc analysis of subjects with T2DM at baseline evaluated WL based on baseline EOSS category, changes in HbA1c, and net change in percentage of subjects receiving antidiabetic medications (percent subjects increasing-decreasing) across the overall population with T2DM.

**Materials and methods:** CONQUER randomised 2487 subjects to PBO, PHEN 7.5 mg/TPM ER 46 mg (7.5/46), or PHEN 15 mg/TPM ER 92 mg (15/92), 388 (15.6%) of whom had T2DM at baseline ( $n=157$ ,  $n=67$ , and  $n=164$  for PBO, 7.5/46, and 15/92, respectively). In subjects with T2DM, baseline EOSS was scored as follows: 2=established weight-related chronic disease ( $n=347$ ) and 3=established end-organ damage ( $n=41$ ). Diet/exercise or metformin monotherapy were permitted at enrollment. Changes in concomitant drug treatment by physicians blinded to treatment-group assignment were permitted.

**Results:** At week 56 in subjects with T2DM at baseline, greater WL was observed among those receiving PHEN/TPM ER compared with those receiving PBO in both baseline EOSS categories (Table). Significant decreases in HbA1c were also observed with PHEN/TPM ER vs PBO ( $P < .05$ ; Table). In addition, 12.1%, 1.5%, and 0.6% of subjects receiving PBO, 7.5/46, and 15/92, respectively, experienced a net change in antidiabetic medications (percent subjects increasing-decreasing). Discontinuation due to adverse events in subjects with T2DM was 8%, 9%, and 19% for placebo, 7.5/46, and 15/92, respectively, with the most common adverse events being upper respiratory tract infection, constipation and paraesthesia.

**Conclusion:** PHEN/TPM ER treatment significantly reduced weight when compared with PBO, even in comorbid subjects based on EOSS category. This WL was associated with significant improvements in HbA1c in subjects with T2DM.

Table. PHEN/TPM ER effects on weight and HbA1c (T2DM population; ITT-LOCF)

			PBO	7.5/46	15/92
Weight loss from baseline to week 56 by baseline EOSS score	Baseline EOSS score 2 (n=347)	Baseline weight, kg	99.4	97.2	102.4
		Week 56 weight, kg	97.4	90.4	93.6
		LS mean weight loss, %	1.9	6.9*	8.5*
	Baseline EOSS Score 3 (n=41)	Baseline weight, kg	97.9	97.7	109.3
		Week 56 weight, kg	95.6	91.4	97.3
		LS mean weight loss, %	2.3	6.6	10.8†
PHEN/TPM ER effects on HbA1c	Overall population (n=357)	Baseline HbA1c, %	6.8	6.8	6.8
		Week 56 HbA1c, %	6.7	6.4	6.4

## 697

### Effects of phentermine and extended-release topiramate alone and in combination on cardiovascular risk factors

J. Jordan<sup>1</sup>, A.V. Astrup<sup>2</sup>, W.W. Day<sup>3</sup>;

<sup>1</sup>Institute of Clinical Pharmacology, Hannover, Germany, <sup>2</sup>Department of Human Nutrition, LIFE, University of Copenhagen, Frederiksberg, Denmark, <sup>3</sup>Vivus, Inc., Mountain View, USA.

**Background and aims:** Obesity is associated with an increased risk of cardiovascular disease. In EQUATE, a 28-week, double-blind, placebo-controlled Phase 3 trial, the cardiovascular efficacy and safety of phentermine (PHEN), extended-release topiramate (TPM ER), and the combination of PHEN/TPM ER were assessed.

**Materials and methods:** In this study, 756 subjects were randomized to placebo ( $n=109$ ), PHEN 7.5 mg monotherapy ( $n=109$ ), PHEN 15 mg monotherapy ( $n=108$ ), TPM ER 46 mg monotherapy ( $n=108$ ), TPM ER 92 mg monotherapy ( $n=107$ ), PHEN 7.5 mg/TPM ER 46 mg ( $n=107$ ), or PHEN 15 mg/TPM ER 92 mg ( $n=108$ ). In addition to the primary efficacy endpoint of percent weight loss at week 28, cardiovascular measures included systolic blood pressure (SBP) and diastolic blood pressure (DBP) in the ITT-LOCF sample and heart rate (HR) in the safety set. Adverse events were also assessed during the trial. Across the entire Phase 3 program, major cardiovascular adverse events were assessed retrospectively.

**Results:** After 28 weeks of treatment, least-squares (LS) mean percent weight loss was greater in all arms vs placebo (Table). In addition, SBP and DBP were improved in all arms vs placebo (Table). In the safety set ( $n=753$ ), HR was decreased in the placebo, TPM ER monotherapy, and combination arms from baseline to week 28 but was increased in the both the PHEN monotherapy arms (Table). In total, 72 (9.6%) subjects discontinued due to any drug-related treatment-emergent adverse event: 6 in placebo, 9 in PHEN 7.5 mg, 8 in PHEN 15 mg, 7 in TPM ER 46, 14 in TPM 92 mg, 10 in PHEN 7.5 mg/TPM ER 46 mg, and 18 in the PHEN 15 mg/TPM ER 92 mg groups. The most common adverse events were upper respiratory tract infections, paraesthesia, and dry mouth. Cardiovascular adverse events were infrequent, with the most common being palpitations.

**Conclusion:** PHEN/TPM ER led to significant weight loss and reduced BP compared with placebo. TPM ER monotherapy and PHEN/TPM ER were both associated with reduced HR whereas subjects receiving PHEN monotherapy experienced a slight increase in HR.

Table. Changes in weight, SBP, DBP, and HR from baseline to week 28

	LS mean change (ITT-LOCF population)		Mean change (safety set)	
	Percent weight loss, %	SBP, mm Hg	DBP, mm Hg	HR, bpm
Placebo	1.7	-1.8	-0.7	-1.9
PHEN 7.5 mg	5.5	-3.3	-1.5	0.9
PHEN 15 mg	6.1	-3.5	-0.9	1.1
TPM ER 46 mg	5.1	-6.8	-2.6	-3.8
TPM ER 92 mg	6.4	-6.4	-3.9	-4.5
PHEN 7.5 mg/TPM ER 46 mg	8.5*	-7.0†	-2.2	-1.6
PHEN 15 mg/TPM ER 92 mg	9.2*	-5.2†	-2.0	-1.6

\* $P < .0001$  vs placebo; † $P < .05$  vs placebo.

### Microarray analysis of diabetic gene expression profile in mouse heart overexpressing adipose differentiation-related protein

J. Suzuki<sup>1</sup>, M. Ueno<sup>1</sup>, M. Ichikawa<sup>1</sup>, M. Imagawa<sup>1</sup>, S. Sato<sup>1</sup>, Y. Zenimaru<sup>1</sup>, T. Koizumi<sup>2</sup>, S. Ikuyama<sup>3</sup>, S. Takahashi<sup>1</sup><sup>1</sup>Endocrinology and Metabolism, University of Fukui, Faculty of MedicalScience, Eihei, <sup>2</sup>Laboratory Animal Resources, University of Fukui, Eihei, <sup>3</sup>The medical institute of bioregulation, University of Kyushu, Oita, Japan.

**Background and aims:** Diabetic cardiomyopathy is characterized by intracellular lipid accumulation (steatosis) that generates lipotoxicity and eventually leads to cardiac dysfunction. The adipose differentiation-related protein (ADRP) is a lipid droplet-associated molecule expressed in many tissues including heart. Since we found that the expression of ADRP was dysregulated in diabetic heart, we have created heart-specific ADRP-overexpressing (Tg) mice to study function of cardiac ADRP in diabetic condition. We have reported in 2011 session that despite massive steatosis, Tg mice maintained normal cardiac function with decreased expression of fatty acid-responsive genes. In the current study we further analyzed cardiac gene expression profile using microarray to address the pathophysiology of lipotoxic cardiomyopathy.

**Materials and methods:** Tg mice and wildtype (Wt) littermates were treated with streptozotocin to induce diabetes. The hearts were collected 3-weeks afterwards and gene expression profile was analyzed using Affymetrix microarrays. Comparison analyses were performed among 4 groups; control Wt, diabetic Wt, control Tg and diabetic Tg mice, and the selected genes were analyzed by qRT-PCR. Pathway analysis for the altered genes was performed using KEGG database, and gene ontology (GO) classification was carried out through GO Slim database.

**Results:** The induction of diabetes altered (>2-fold) expression of 810 genes in Wt hearts and 1141 genes in Tg hearts. In Wt hearts 17 pathways were identified to be affected significantly by the induction of diabetes through KEGG pathway analysis. The 17 pathways included PPAR signaling, Ca signaling, and dilated cardiomyopathy. In contrast, in Tg hearts only 2 pathways out of the 17 pathways were identified to be affected. Importantly, 5 genes involved in PPAR signaling were differentially expressed with diabetes in Tg hearts compared to Wt hearts. GO classification identified 12 unique functional groups induced by diabetes in Tg hearts. Among them, gene group of cell motility and homeostatic process were differentially regulated in Tg hearts compared with Wt hearts.

**Conclusion:** Packaging excess fatty acids into lipid droplets, cardiac ADRP might play a role in counteracting diabetes-induced gene expression in heart. Thus, cardiac ADRP could be a target to regulate cardiac lipotoxicity in diabetes.

#### Pre-existing type 2 diabetes and mortality of cancer patients in Latvia

I. Strele<sup>1</sup>, S. Pildava<sup>2</sup>, G. Brigis<sup>1</sup><sup>1</sup>Riga Stradins University, <sup>2</sup>National Health Service, Riga, Latvia.

**Background and aims:** Studies show that cancer patients with pre-existing diabetes experience higher all-cause mortality compared to non-diabetic cancer patients. Explanations of that association vary from timely detection of cancer to different cancer treatment practices and side-effects. We compared all-cause mortality between cancer patients with and without prior type 2 diabetes, considering also the cancer stage at diagnosis.

**Materials and methods:** The data source was two nationwide Cancer and Diabetes Registers. All patients from 2005 to 2009 with the first incident tumor were selected and their diabetes status ascertained. Patients with type 1 and other specific types of diabetes were excluded, as well as cases in which diabetes and cancer occurred in the same year. Thus, the study included 25,180 male and 26,906 female patients with cancer, of those 1,493 and 2,383, respectively, had type 2 diabetes prior the diagnosis of cancer. Cox regression was used to assess the all-cause mortality difference, shown as a hazard ratio (with 95%CI) with non-diabetic cancer patients as the reference group. As diabetes patients were older, both among men (mean age 69.6 vs. 64.9 years) and women (mean age 71.0 vs. 64.0 years), the estimates presented were adjusted for age at cancer diagnosis.

**Results:** Among men, cancer patients with diabetes had an even lower mortality within the first five follow-up years than cancer patients without diabetes: HR 0.84 (0.78-0.90),  $p < 0.001$ . Analysis according to specific cancer site resulted in a few statistically significant findings. Among men with lung and tracheal cancer, prior diabetes was associated with lower mortality: HR 0.83 (0.69-0.98),  $p = 0.026$ . In the case of prostate cancer, patients with pre-existing diabetes had increased mortality, but only after the first five years of follow-up: HR 2.42 (1.19-4.89),  $p = 0.014$ . Further adjustment for cancer stage did not substantially change these estimates. Among women, cancer patients with diabetes, overall, experienced a mortality similar to that of cancer patients without diabetes: HR 1.06 (0.99-1.13),  $p = 0.055$ ; however, the difference increased after adjusting for cancer stage: HR 1.10 (1.03-1.16),  $p = 0.003$ . Specifically, this pattern was observed in women with colon or breast cancer: HR when adjusted only for age was 1.16 (0.95-1.40),  $p = 0.141$  in the case of colon cancer and 1.02 (0.86-1.22),  $p = 0.784$  in the case of breast cancer; although, after adjustment for stage, it became 1.25 (1.02-1.52),  $p = 0.025$  and 1.19 (1.01-1.42),  $p = 0.044$ , respectively. But in ovary cancer, association of diabetes and mortality changed over time. If mortality risk was slightly increased and not statistically significant within the first 1.5 years, then in women who survived the first 1.5 years since diagnosis, pre-existing diabetes was associated with better subsequent survival: HR 0.46 (0.25-0.84),  $p = 0.011$ .

**Conclusion:** In Latvia, cancer patients with prior type 2 diabetes do not experience increased all-cause mortality, at least within the first five years since cancer diagnosis. Overall, cancers in the diabetic population were not diagnosed at more advanced stages, but in women with diabetes, even an earlier cancer stage was responsible for survival similar to that of non-diabetic women. As diabetes patients regularly contact the health care system, then, probably, low screening uptake and late cancer detection in the general population reduce this difference.

### 700

#### Cancer mortality among Danish diabetic patients compared to patients without diabetes

K. Ranc<sup>1</sup>, M.E. Jorgensen<sup>1</sup>, D.R. Witte<sup>1</sup>, B. Carstensen<sup>1,2</sup><sup>1</sup>Steno Diabetes Center, <sup>2</sup>Department of Biostatistics, University of Copenhagen, Denmark.

**Background and aims:** It is known that cancer patients with pre-existent diabetes experience higher mortality compared to cancer patients without diabetes. However, the role of different diabetes treatment types has not been studied in detail. We compared mortality rates among cancer patients with and without diabetes, accounting for treatment.

**Materials and methods:** The study is based on all cancer patients diagnosed in Denmark in the period 1995-2009. We linked the Danish Cancer Register (DCR) and the Danish National Diabetes Register (NDR). Cancer patients were classified into 4 groups according to diabetes status at the time of diag-

nosis of cancer: no diabetes, diabetes without medication, diabetes with only OAD treatment or diabetes with Insulin treatment. Cox proportional hazard models were used to estimate sex and age adjusted cancer mortality hazard-ratios relative to non-diabetic cancer patients.

**Results:** Among 426,129 new cancer cases, we found 42,484 that had diabetes prior to the cancer diagnosis (14,315 without medication history, 17,699 on OADs and 8,582 on Insulin). Over all, diabetes patients had a higher mortality rate compared to non-diabetic cancer patients. Cancer patients with insulin treated diabetes had a 48% (95%CI: 1.45–1.52) higher mortality, those with OAD treated diabetes had a 23% (95%CI: 1.21–1.26) higher mortality, and those with diabetes without medication had a 13% (95%CI: 1.11–1.15) higher mortality than non-diabetic cancer patients.

**Conclusion:** Based on a nation-wide register linkage study, we confirmed that cancer patients with pre-existing diabetes experience higher mortality than cancer patients without diabetes. The higher mortality seen among cancer patients with OAD and insulin treated diabetes respectively is in accordance with the notion that more intensive diabetes treatment reflects a larger degree of co-morbidity at the time of cancer diagnosis, and hence poorer survival.

## 701

### Postprandial blood glucose predicts cancer mortality in type 2 diabetes mellitus: lessons from the 14-year follow-up of the San Luigi Gonzaga diabetes study

F.L. Cavalot, A. Pagliarino, M. Valle, L. Di Martino, K. Bonomo, P. Poy, C. Vaccheris, M. Trovati;

Dept of Clinical and Biological Sciences, University of Turin, Orbassano, Italy.

**Background and aims:** Type 2 diabetes mellitus (T2DM) has been associated with a variety of neoplasms. Among the factors that have been involved in this relationship, obesity, insulin-resistance, hyperinsulinemia and type of therapy should be mentioned. If blood glucose (BG) control plays any role in predicting cancer mortality in T2DM has not been clarified so far; furthermore, if postprandial blood glucose (PPBG), that we and others have shown to predict cardiovascular events and total mortality, also predicts cancer mortality is completely unknown. Aim of the present study was to evaluate the predictive power of HbA1c, fasting BG (FBG) and PPBG on cancer mortality in a long-term follow-up of patients affected by T2DM.

**Materials and methods:** We studied, in a 14-year follow-up, 622 T2DM patients (M/F 340/282, age:  $62.1 \pm 9.4$  years, known diabetes duration:  $9.6 \pm 7.9$  years) belonging to the San Luigi Gonzaga Diabetes Study cohort in Turin, Piedmont, North West of Italy. In these patients, at the enrollment in 1995 data were collected concerning glycated haemoglobin HbA1c, FBG, BG 2 hours after lunch (PPBG) and the main cardiovascular risk factors. Subjects were followed for many outcomes, among them the cause of death. We performed Cox analysis with the backward method in order to evaluate the predictive power for cancer mortality of HbA1c, FBG, and PPBG measured at baseline and adjusted for age, gender, known diabetes duration, smoking habit, body mass index, systolic and diastolic blood pressure, total and HDL cholesterol, triglycerides, albumin excretion rate and serum creatinine. We built four models, in which all the non-glycaemic variables were included as correctors, whereas the glycaemic variables were included as follows: Model A, HbA1c; Model B, FBG; Model C, PPBG; Model D, HbA1c, FBG and PPBG. The glycaemic variables were inserted in the Models as continuous values.

**Results:** At the follow-up, 192/622 patients died, 49 as a consequence of cancer. In all Models, age and smoking habit resulted to be the significant non-glycaemic predictors. In Model A, the HR per 1% HbA1c was 1.241, CI 1.015–1.517,  $p=0.036$ ; in Model B, FBG was not a predictor, with HR per 1 mmol/L 1.066, CI 0.965–1.177,  $p=ns$ ; in Model C, the HR per 1 mmol/L PPBG was 1.108, CI 1.021–1.202,  $p=0.014$ ; in Model D, the only significant glycaemic predictor was PPBG, its HR per 1 mmol/L being 1.108, CI 1.021–1.202,  $p=0.014$  (as in Model C).

**Conclusion:** Blood glucose control is a predictor of cancer mortality in T2DM. Among the glycaemic variables considered, FBG does not predict cancer mortality, HbA1c is a predictor only in Models that do not include also PPBG, while PPBG is a predictor by itself and remains the only glycaemic predictor of cancer mortality when included together with FBG and HbA1c in the statistical Models. On the basis of these data, we can conclude that PPBG is the most relevant component of blood glucose control to play a predictive role for cancer mortality in T2DM.

## 702

### Interrelation between prevalence rates of diabetes and of malignant neoplasms evaluated by crossing different databases: a retrospective study

F. Bardelli<sup>1</sup>, F. Tesi<sup>2</sup>, R. Anichini<sup>2</sup>, G. Seghieri<sup>2</sup>;

<sup>1</sup>Pharmaceutical Service Dpt., <sup>2</sup>Dpt. of Internal Medicine, Pistoia, Italy.

**Background and aims:** The relationship between cancer and diabetes has been for a long time well-known, and the upward trend of prevalence/incidence rates of both diabetes and malignant neoplasms (MN) is likewise known. With the purpose of obtaining indirect information about relationship between rates of MN and of diabetes in our population we have utilized the pharmaceutical registry databases (PRD) of local health area which covers a population of about 280,000 inhabitants.

**Materials and methods:** PRD contains records of all patients who received prescriptions for antidiabetic drugs (oral and insulin), which are totally reimbursed by the Regional Health System as well as records of patients exempted from payment for medical services because affected by neoplastic diseases. Consequently PRD has been screened across a 6-years-period from 2006 to 2011 to obtain a reasonable proxy esteem of time-related interrelation between prevalence of diabetes and of MN.

**Results:** Population rose from 279,061 inhabitants (134,340M/144,721F) in 2006 to 293,061 (140,626M/152,435F) in 2011, and during this period we observed a parallel increase in the rate of patients who were given prescriptions for antidiabetic drugs, expressed as % of total population, from 4.06% to 4.47% (from 4.23% to 4.48% in males and from 3.90% to 4.18% in females). Likewise we also observed a progressive increment of those exempted from payment for medical services because affected by neoplastic diseases from 2.23% in 2006 to 3.38% in 2011. Within the group of treated diabetic patients we noticed a progressive increase in prevalence of neoplastic patients from 508 (4.93%), in January 2006 to 868 (6.63%) in December 2011, and specularly there was an upward trend for prevalence of diabetic patients in the group of neoplastic patients (7.9% in 2006, 8.5% in 2007, 8.8% in 2008, 9.2% in 2009, 9.4% in 2010 and 9.6% in 2011;  $p=0.0001$  for trend test). However relative risk (95%CI) of co presence of diabetes and MN remained similar in 2006 and in 2011 [2.23 (1.13–2.89) in 2006 and 2.06 (1.14–2.92)] in 2011. Throughout the entire period the ratio M/F was  $>1$ , among diabetics, while remained persistently  $<1$  in neoplastic patients whether diabetic or not.

**Conclusion:** According to this preliminary study crossing data from different PRD databases allows us to suggest that: a) both prevalence of neoplastic disease in diabetic patients and prevalence of diabetes in neoplastic patients are progressively growing with time, b) in spite of increasing rates of treated diabetes and of patients with exemption for MN relative risks of co presence of both pathologies remain constant with time, with diabetic patients presenting a twice higher relative risk for MN, and c) female gender predominates among neoplastic patients whether they are suffering from diabetes or not.

### Insulin resistance as a link between type 2 diabetes mellitus and colon cancer

P.J. Piattkiewicz<sup>1</sup>, A. Czech<sup>1</sup>, T. Milek<sup>2</sup>, M. Bernat-Karpinska<sup>1</sup>, A. Górski<sup>3</sup>;

<sup>1</sup>Chair and Department of Internal Diseases and Diabetology, <sup>2</sup>Chair and Department of General and Vascular Surgery, <sup>3</sup>Department of Clinical Immunology, Warsaw Medical University, Poland.

**Background and aims:** In subjects with type 2 diabetes there is a more significant occurrence of colon cancer. The aim of this study was to evaluate the possible differences in glucose metabolism parameters and insulin resistance indicators in Type 2 diabetic patients with negative family history of cancer (T2DP), Type 2 diabetic patients with newly diagnosed untreated colon cancer (T2DCCP), and subjects without diabetes with newly diagnosed, untreated colon cancer (CCS). The specific objective of this study was to verify the hypothesis that the positive relationship between type 2 diabetes and colon cancer may be associated with the applied method of type 2 diabetes treatment.

**Materials and methods:** 18 T2DP treated with diet and oral antidiabetic agents (metformin or sulfonylurea), 19 T2DCCP cT1-4N0M0 (c-clinical diagnosis based on computer tomography, colonoscopy and histopathology) treated with diet and oral antidiabetic agents (metformin or sulfonylurea), and 20 normoglycemic CCS cT1-4N0M0 were enrolled into the study. The operation was conducted in a period of up to 14 days after the clinical diagno-

sis had been made. Histopathological results verified the clinical diagnosis. In all analyzed cases, the presence of adenocarcinoma was registered. Due to the finding of metastases in mesenteric lymph nodes, 4 patients were excluded from the CCS group and 3 patients from the T2DCCP group. The control group included 18 metabolically healthy subjects (HS) with negative family history of cancer, matched with age, BMI and waist circumference.

**Results:** Duration of diabetes was similar in T2DP and T2DCCP respectively ( $6,3 \pm 2,9$  vs.  $6,5 \pm 3,0$ ). However T2DCCP differed significantly from T2DP in terms of therapy of type 2 diabetes. In T2DP the predominant anti-diabetic drug was metformin, which was used in 83.3% of patients. 75% of T2DCCP were treated with a sulfonylurea. The anthropometric and biochemical parameters of the study groups are presented in the table. (Table).

**Conclusion:** This study indicates a positive and statistically significant correlation between the high levels of endogenous insulin in plasma and an increased risk of colon cancer. Our study also shows that metformin intake reduces the risk of colon cancer. On the contrary, the mode of therapy for type 2 diabetes, which is directly linked to augmenting endogenous insulin levels, increases the risk of colon cancer. Thus, the kind of treatment applied for type 2 diabetic patients may modify the risk of colon cancer. The frequent screening tests towards colon cancer in subjects with type 2 diabetes, especially in those with coexisting insulin resistance seems to be of a great purpose.

Table (p-values are related to HS group).

PARAMETER (x ± SD)	HS	T2DP	CCS	T2DCCP
NUMBER	18	18	16	16
SEX (M/F)	8 / 10	9 / 9	7 / 9	8 / 8

### Comparative assessment of event rates of bladder cancer and nine other cancers in patients with type 2 diabetes mellitus treated with pioglitazone or insulin

C. Vallarino<sup>1</sup>, J. Yang<sup>2</sup>, A. Perez<sup>1</sup>, G. Fusco<sup>1</sup>, H. Liang<sup>1</sup>, M. Bron<sup>2</sup>, V. Harikrishnan<sup>2</sup>, G. Joseph<sup>1</sup>, S. Yu<sup>2</sup>

<sup>1</sup>Takeda Global Research & Development Center, Inc., Deerfield, USA,

<sup>2</sup>Takeda Pharmaceuticals International, Inc., Deerfield, USA.

**Background and aims:** To address concerns about a possible increased risk of bladder cancer in type 2 diabetes mellitus (T2DM) patients receiving pioglitazone, a retrospective cohort study was designed to assess the event rates of bladder cancer and a composite of nine other selected cancers (prostate, female breast, lung, pancreatic, endometrial, non-Hodgkin's lymphoma, colorectal, kidney and malignant melanoma) among new users of pioglitazone (PIO) or insulin (INS).

**Materials and methods:** Data from May 1, 2000 to June 30, 2010 were extracted from the i3 InVision Data Mart, a US medical and prescription records database representing approximately 47 million covered lives during the period of analysis. Key outcomes were incident cases of bladder cancer and incident cases of nine other cancers. As pre-planned additional analyses, a composite endpoint of all-cause mortality and bladder cancer and a composite endpoint of all-cause mortality and nine other cancers were also created using death records obtained from the US Social Security Administration in March 2012. Kaplan-Meier curves were generated and hazard ratios (HR) estimated from Cox proportional hazards models adjusted with inverse probability weights derived from propensity scores.

**Results:** A total of 56,536 patients (PIO group: 38,588; INS group: 17,948) aged ≥45 years qualified for the study (mean age: 58.1 and 59.7 years, male gender: 59.6% and 53.0%, mean follow-up: 2.2 and 1.9 years, for PIO and INS; respectively). For bladder cancer, the incidence rate showed no significant difference between the two groups; the HR for PIO vs INS was 0.92 (95% con-

fidence interval (CI) [0.63, 1.33], *p*=0.64). The results were similar for bladder cancer with additional confirmation based on cancer-related procedures, which served as a sensitivity check. There was no evidence of the incidence rate of bladder cancer increasing with time of exposure to PIO. Cox regression results for the composite of nine other cancers yielded an HR for PIO vs INS of 0.78 (95% CI [0.71, 0.85], *p*<0.0001). The raw incidence rates of nine other cancers for PIO and INS were 1798 and 2456 per 100,000 person years, respectively, which were 16 times higher than the rate of bladder cancer alone (PIO: 113; INS: 152). The risk of all-cause mortality plus bladder cancer was lower in the PIO group compared with the INS group; the HR for PIO vs INS was 0.40 (95% CI [0.36, 0.44], *p*<0.0001). Similarly, the risk of all-cause mortality plus nine other selected cancers was also lower in the PIO group; the HR for PIO versus INS was 0.58 (95% CI [0.54, 0.62], *p*<0.0001).

**Conclusion:** The results indicate that, compared to INS, PIO was not associated with an increased risk of bladder cancer. Additionally, PIO was associated with a significantly lower risk of developing other selected cancers. When all-cause mortality was included in the analysis, the risks of all-cause mortality plus bladder cancer and all-cause mortality plus nine other selected cancers were both considerably lower in the PIO group than in the INS group. ### Metformin prevents high-fat diet-induced liver tumorigenesis in C57BL/6J mice

K. Tajima, A. Nakamura, J. Shirakawa, K. Orime, Y. Togashi, Y. Nagashima, Y. Terauchi;  
Yokohama City University, Japan.

**Background and aims:** We previously demonstrated that long-term high-fat (HF) diet loading induced NASH and liver tumorigenesis in C57BL/6J mice, and that liver fat accumulation was involved in the development of tumorigenesis. Metformin, one of the most widely used oral hypoglycemic agents, has recently increased attention because of its potential anti-tumor effects. Here, we investigated the effects of metformin on HF diet-induced liver tumorigenesis using mouse model of NASH and liver tumorigenesis.

**Materials and methods:** We challenged 8-week-old C57BL/6J male mice with the standard chow diet (SC group), a HF diet (HF group) or a HF diet with treatment of metformin in drinking water (250 mg/kg/day) (HF+Met group) for 60 weeks. We also treated HF diet-induced NASH model mice with metformin. Eight-week-old C57BL/6J mice were administered the HF diet for 30 weeks, followed by HF diet with metformin for another 30 weeks (HF-HF+Met group) and they were compared with mice on the HF diet throughout the 60 weeks (HF-HF group). The histological and phenotypical analyses were performed.

**Results:** After 60 weeks, the HF group showed significantly increased body weight, liver weight and plasma alanine aminotransferase (ALT) levels as compared with the SC group. Although the body weight of HF+Met group was comparable to the HF group, metformin treatment significantly decreased liver weight and plasma ALT levels. The triglyceride (TG) content in the liver was comparable between the HF and HF+Met group. Scoring of the pathological findings showed a significant increase in the scores for liver steatosis, inflammation and fibrosis in the HF group as compared with the SC group. Of note, metformin treatment significantly improved the scores for inflammation and fibrosis, but not steatosis compared with the HF group. The incidence of the nodular lesions on the liver surface was significantly decreased in the HF+Met group as compared with the HF group (25% vs. 70%). We next investigated whether metformin prevented NASH model mice that had been administered HF diet for 30 weeks from the development of liver tumors. The body weight, liver weight and TG content in the liver were comparable between the HF-HF and HF-HF+Met group. Moreover, the incidence of nodular lesions on the liver surface was not different between HF-HF group and HF-HF+Met group (75% vs. 83%). We next assessed the short-term effect of metformin on HF diet-induced liver fat accumulation. Hepatic histopathology and TG levels showed that hepatic triglyceride content was larger in the HF group after 8 weeks than in the SC group, and was decreased by metformin treatment. With regard to adipose tissue function, the adipocyte size of the epididymal fat in the HF group was larger than in the SC group, and was decreased by metformin treatment. In addition, the mRNA expression levels of F4/80 and CD11c were significantly higher in the HF group than the SC group, whereas they were decreased by metformin treatment.

**Conclusion:** Metformin prevented HF diet-induced liver tumorigenesis in C57BL/6J Mice. On the contrary, additional treatment of metformin failed to

reduce the incidence of liver tumorigenesis. These results suggested that the mechanism underlying anti-tumour effect of metformin was at least partly associated with suppression of liver fat accumulation at early stage. Suppression of liver fat accumulation by metformin may be associated with the prevention from adipose tissue dysfunction by HF-feeding, but further study is needed to address this association.

## 706

### The effect of rhIGF-1 and insulin analogue AspB10 on mammary tumour growth and progression in a mouse model of type 2 diabetes

E.J. Gallagher<sup>1</sup>, N. Alikhani<sup>1</sup>, A. Tobin-Hess<sup>1</sup>, D. Cannata<sup>1</sup>, N. Tennagels<sup>2</sup>, U. Werner<sup>2</sup>, D. LeRoith<sup>1</sup>;

<sup>1</sup>Samuel Bronfman Dept of Medicine, Mount Sinai School of Medicine, New York, USA, <sup>2</sup>R&D Diabetes Division, Sanofi, Frankfurt, Germany.

**Background and aims:** Epidemiological studies have clearly demonstrated the association between obesity, type 2 diabetes (T2D) and an increased risk of developing cancer and cancer-related mortality. This may be attributable to hyperinsulinemia, hyperglycemia, hyperlipidemia or factors such as leptin, IGF-1 and inflammatory cytokines. One of the malignancies adversely affected by obesity and T2D is breast cancer. The MKR mouse is a model of T2D. The females are hyperinsulinemic, lean, display a mild dysglycemia and have normal circulating IGF-1 levels. The female MKR mice have been utilized in our previous studies to demonstrate the role of endogenous hyperinsulinemia in mammary tumor growth, without the confounding variable of obesity. In the present study, we are investigating the effect of IGF-1 and human insulin analog AspB10, in addition to endogenous hyperinsulinemia, on mammary tumor growth and progression.

**Materials and methods:** Non-metastatic Met-1 and metastatic Mvt-1 mammary cancer cells derived from MMTV-PyVmT/FVB-N transgenic mice and c-Myc/vegf tumor explants respectively, were inoculated into the 4th mammary fat pad of MKR females. Mice were divided into 2 groups matched for tumor size and were treated with rhIGF-1 (2mg/kg/day i.p.) or vehicle for 14 days in the initial study, and with AspB10 (12.5IU/kg twice daily s.c.) or vehicle for 14 days in the second study.

**Results:** Treating the MKR mice with rhIGF-1 and AspB10 insulin analog respectively, resulted in significantly increased tumor growth, when compared to vehicle treated MKR mice, as measured by tumor volume over a 28 day period. (Mvt-1 tumors: 170 mm<sup>3</sup> in rhIGF-1 treated vs 68 mm<sup>3</sup> in vehicle treated; Met-1 tumors: 55 mm<sup>3</sup> in rhIGF-1 treated vs 31 mm<sup>3</sup> in vehicle treated; Mvt-1 tumors: 144 mm<sup>3</sup> in AspB10 treated vs 73 mm<sup>3</sup> in vehicle treated; Met-1 tumors: 72 mm<sup>3</sup> in AspB10 treated vs 35 mm<sup>3</sup> in vehicle treated,  $p < 0.05$ ).

**Conclusion:** These results indicate an independent effect of rhIGF-1 and AspB10 in mammary tumor growth in the setting of a hyperinsulinemic non-obese environment. We are currently investigating the receptor and signaling pathway through which IGF-1 and AspB10 promote mammary tumor growth in the hyperinsulinemic milieu.

### Effects of the inhibition of insulin degrading enzyme (IDE) activity on the liver cancer cells transcriptome

N.N. Rudovich<sup>1,2</sup>, O. Pivovarova<sup>1,2</sup>, I. Ilkavets<sup>3</sup>, C. Sticht<sup>4</sup>, S. Zhuk<sup>5</sup>, A. Malashicheva<sup>5</sup>, C. Bumke-Vogt<sup>1</sup>, S. <sup>1</sup>Clinical Nutrition, DIFE Potsdam, Nuthetal, Germany, <sup>2</sup>Campus B. Franklin, Charite University of Berlin, Berlin, Germany, <sup>3</sup>Molecular Hepatology - Alcohol Associated Diseases, Medical Clinic, Faculty of Medicine Mannheim at Heidelberg University, Germany, <sup>4</sup>Center for medical research (ZMF), Faculty of Medicine Mannheim at Heidelberg University, Mannheim, Germany, <sup>5</sup>Institute of Molecular Biology and Genetics, Almazov Federal Heart, Blood and Endocrinology Center, Saint-Petersburg, Russian Federation.

**Background and aims:** Type 2 diabetes mellitus (T2DM) characterized by hyperinsulinemia is an independent risk factor for development and progression of hepatocellular carcinoma. Insulin degrading enzyme (IDE) is a major enzyme responsible for insulin degradation in the liver. We and others demonstrated that metabolic modulation of IDE activity is superior compared to its alteration at protein level. Inhibition of IDE activity results in increased intracellular insulin concentration, which might be crucial for insulin-depend-

ent regulation of gene expression and cell proliferation. Therefore, modulating IDE activity may represent a key link between T2DM and liver cancer. Here, we characterized variations in the gene expression of HepG2 hepatoma cell line upon modulation of IDE activity.

**Materials and methods:** We analyzed the HepG2 cell transcriptome under four conditions: in untreated cells or after insulin treatment (10 nM insulin for 24 h) with or without inhibition of IDE activity. To modulate IDE activity in HepG2 cells, known IDE inhibitors (bacitracin, N-ethylmaleimide, 1,10-phenanthroline) or IDE silencing (RNAi) were used. Gene expression profiling was performed of HUGene-1.0-st-v1-type from Affymetrix which allows monitoring of expression of about 19 000 transcripts. In addition, we measured mRNA expression of IDE gene with Real Time PCR in liver normal and cancer cells lines with different proliferative capacity (HepG2, HCC-M, HCC-T, Hep3B, HLF, PLC4, FLC4, HLE and Huh7).

**Results:** All used chemical inhibitors demonstrated toxicity for HepG2 cells in concentrations, which are effective to inhibit IDE activity according to literature data. Therefore, only IDE RNAi was used in experiments for transcriptome analyses. The IDE-knockdown regulated a greater part of transcriptome in comparison with insulin effects (0.05% vs 0.71% by  $p < 0.05$  with FDR-correction). In basal state, IDE silencing led to the regulation of genes related to MAPK and p53 signaling pathways as well as endocytosis and ligand-receptor interactions. Insulin treatment in IDE knockdown cells resulted in expression alterations of cell cycle genes that were not detected in control cells. Moreover, proliferation markers MKI67, MCM2 and PCNA were significantly upregulated upon RNAi for IDE. In Huh7 and HCC-T cells IDE gene expression was strong down regulated.

**Conclusion:** Inhibition of IDE activity can lead to insulin mediated upregulation of proliferation pathway genes in liver cells. Thus, IDE becomes a potential target for therapeutic intervention in T2DM and cancer.

## 708

### Metformin attenuates proteasome 26S activity and exerts tumour-suppressing effects in human hepatoma cells

A. Obara, Y. Fujita, A. Abudukadier, T. Fukushima, M. Hosokawa, N. Inagaki; Department of Diabetes and Clinical Nutrition, Graduate School of Medicine, Kyoto University, Japan.

**Background and aims:** Metformin is widely prescribed as an oral anti-hyperglycemic drug for treatment of type 2 diabetes, and metformin comes to the front by its anti-carcinogenic effect. This effect is induced by suppression of mTOR signaling in breast and prostate cancer cells. Recent studies have shown that mTOR signaling is regulated by the proteasome degradation system. Although the major target tissue of metformin is liver and several clinical studies show that metformin reduces the risk of hepatocellular carcinoma and lowers mortality in diabetic patients, the effect of metformin in suppressing cell proliferation in liver remains unknown. The aim of this study was to investigate the effect of metformin on cell proliferation and the role of the proteasome degradation system in liver cancer cells.

**Materials and methods:** HepG2 cells were maintained in Dulbecco's modified Eagle's medium (DMEM) containing 5.6 mmol/l glucose supplemented with 10 % (vol./vol.) fetal bovine serum. HepG2 cells were incubated in DMEM treated with metformin, 5-Aminoimidazole-4-carboxamide-1- $\beta$ -D-ribofuranosyl 5'-monophosphate (AICAR), regular insulin, or proteasome inhibitor (MG132). The media were changed every 24 hours. After 72 hours incubation, cell proliferation assay and proteasome activity assay were performed. Cell proliferation rate was determined by MTT assay, absorbance was measured at 490 nm. Proteasome 26S activity was measured by fluorogenic proteasome substrate (N-Succinyl-Leu-Leu-Val-Tyr-7-Amido-4-Methylcoumarin) assay, and absorbance was measured at 360 nm/460 nm. Protein expressions of AMP-activated protein kinase alpha (AMPK alpha), phospho-AMPK alpha, phospho-p70 S6 kinase, and DEPTOR were analyzed by western blotting.

**Results:** Metformin and AICAR significantly suppressed cell proliferation of HepG2 cells over 72-hour incubation. MG132, a proteasome inhibitor, also suppressed cell proliferation, but insulin did not (metformin,  $0.601 \pm 0.032$ ; MG132,  $0.495 \pm 0.011$ ; AICAR,  $0.596 \pm 0.022$ ; insulin,  $0.782 \pm 0.044$ ; control,  $0.836 \pm 0.030$ ; absorbance at 490 nm;  $p < 0.001$  vs control). Metformin attenuated proteasome 26S activity (metformin,  $57.8 \pm 5.7$  % of control;  $p < 0.001$ ). Activation of p70-S6 kinase, a downstream target of mTOR signaling, was suppressed in the presence of metformin. We then investigated the target molecule associated with the mTOR system that is degraded by the proteasome system. As a candidate, we evaluated the expression of DEPTOR, an

mTOR suppressing substrate known to be degraded by the proteasome system, and found that it was increased in the presence of metformin.

**Conclusion:** Metformin suppressed cell proliferation of HepG2 cells. The proteasome degradation system may have an important role in suppression of cell proliferation of liver cancer by metformin.

#### Effects of liraglutide on gastric emptying and postprandial glucose metabolism in obese, non-diabetic adults: a randomised placebo-controlled incomplete crossover trial

E. Blaak<sup>1</sup>, J. van Can<sup>1</sup>, B. Sloth<sup>2</sup>, C.B. Jensen<sup>2</sup>, T.D. Le Thi<sup>2</sup>, A. Flint<sup>2</sup>, W.H.M. Saris<sup>1</sup>;

<sup>1</sup>Maastricht University, Netherlands, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark.

**Background and aims:** This study investigated the effects of once-daily s.c. liraglutide, a human GLP-1 analogue, on gastric emptying (GE) and postprandial (PP) glucose metabolism in obese adults without type 2 diabetes (T2D). Liraglutide 1.8 mg is approved for treatment of T2D while liraglutide 3.0 mg is under development for weight management.

**Materials and methods:** Subjects (N=49, age 18–75 years, BMI 30–40 kg/m<sup>2</sup>) were randomised to once-daily liraglutide 3.0 mg, 1.8 mg, or placebo in a double-blind, incomplete crossover design. GE (paracetamol absorption method) and glycaemic parameters were assessed during a 5-hour meal test after 5 weeks of treatment.

**Results:** Equivalence in GE (AUC<sub>0–300min</sub>; primary endpoint) was observed for liraglutide 3.0 mg vs. 1.8 mg (90% CI contained within [0.80;1.25]) and liraglutide vs. placebo. However, 1-hour GE (AUC<sub>0–60min</sub>) decreased by 23% with liraglutide 3.0 mg (ratio 0.77, 95%CI [0.6;0.9], p=0.007) and 13% with 1.8 mg (ratio 0.87, 95%CI [0.7;1.1], p=0.14) vs. placebo. Liraglutide 3.0 mg and 1.8 mg reduced fasting plasma glucose by 0.5 mmol/L vs. placebo (p<0.0001); no effects on fasting glucagon, insulin or C-peptide were seen. Incremental AUC (iAUC<sub>0–300min</sub>) for glucose decreased with liraglutide 3.0 mg (p=0.02) but not with 1.8 mg (p=0.99) vs. placebo. PP glucagon (iAUC<sub>0–300min</sub>) decreased by about 30% with both liraglutide 3.0 mg (p=0.051) and 1.8 mg (p=0.04). Liraglutide 3.0 mg and 1.8 mg significantly lowered 1-hour PP insulin (iAUC<sub>0–60min</sub>) by 22–26% and C-peptide by 18–21% vs. placebo.

**Conclusion:** Liraglutide 3.0 mg and 1.8 mg were equivalent with respect to 5-hour GE, and not different from placebo. The GE delay with liraglutide 3.0 mg at 1 hour is unlikely to affect absorption of concomitantly administered oral drugs. The clinical relevance of the 1-hour GE delay and improved glycaemic parameters with 3.0 mg will be determined in the ongoing phase 3 programme in obese adults with and without T2D.

#### Effects of Liraglutide (Estimated Means)

	<b>Liraglutide 3.0 mg</b>	<b>Liraglutide 1.8 mg</b>	<b>Placebo</b>
Paracetamol (AUC <sub>0–300 min</sub> ) [min×µg/mL]	2252	2193	2424
Paracetamol (AUC <sub>0–60 min</sub> ) [min×µg/mL]	265*	299	343
FPG (mmol/L)	4.9*	4.9*	5.4
Glucose (iAUC <sub>0–300 min</sub> ) [min×mmol/L]	143**	192	192
Glucagon (iAUC <sub>0–300 min</sub> ) [min×pg/mL]	4866	4781*	6957
Insulin (iAUC <sub>0–60 min</sub> ) [min×mU/L]	3532*	3735*	4778
C-peptide (iAUC <sub>0–60 min</sub> ) [min×ng/mL]	208*	217*	263

AUC = area under the curve, i = incremental, FPG=fasting plasma glucose

\* p<0.05 vs. placebo.

\*\*p<0.05 vs. placebo and vs. liraglutide 1.8 mg.

**Bed time insulin versus GLP-1 analogues in patients with type 2 diabetes: comparison of short-term effects on resting energy expenditure**C. Gonzalez<sup>1</sup>, S. Salandini<sup>1</sup>, A. Pierreisnard<sup>1</sup>, M.-C. Beauvieux<sup>2</sup>, H. Gin<sup>1</sup>, V. Rigalleau<sup>1</sup>;<sup>1</sup>Diabetologie, <sup>2</sup>Biochimie, CHU Bordeaux, Pessac, France.

**Background and aims:** Poorly controlled type 2 diabetic patients (T2D) can be treated with GLP-1 analogues or bed-time insulin therapy with opposite influences on body weight. Beside the effects of GLP-1 analogues on energy intake, it is not known whether changes of Resting Energy Expenditure (REE) contribute to these distinct weight courses. We compared the early effects of both treatments on REE in T2D patients.

**Materials and methods:** Forty nine T2D patients (27 women, 22 men, age: 59±10 years, BMI: 32.8±4.8 kg/m<sup>2</sup>) poorly controlled despite maximal oral therapy (HbA1c: 9.9±1.4%), were included: 21 patients received GLP-1 analogues (exenatide\* 5µg twice-a-day or liraglutide\* 0.6 mg once-a-day); 28 received bed-time insulin analogue (Glargine\* or Detemir\* initial doses 0.2 UI/kg). REE was measured by indirect calorimetry before the first injection (Day0) and during two days (Day1 en 2) after initiating the treatment. Respiratory exchanges were monitored using a sensor MEDICS Vmax 29 N apparatus: VCO<sub>2</sub> and VO<sub>2</sub> were determined on 30 minutes intervals from 8 a.m to 8h30 p.m, before breakfast, and REE was calculated according to Weir's equation.

**Results:** On insulin treatment, REE decreased by -3.5% after the first injection (Day1: 1780±319 vs Day0: 1858±335 Kcal/24h, p<0.05) and by -7.5% after the second injection (Day2: 1713±237 Kcal/24h, P<0.005 vs Day1); REE was unchanged on GLP-1 treatment (Day1: 1829±287 Kcal/24h; Day2: 1861±309 Kcal/24h, NS). REE variations (Day2 vs Day0) were significantly different with these treatments: -162±241 Kcal/24h with Bed-time insulin vs -3 Kcal/24h with GLP-1 analogues; p=0.04. No difference in REE was found between Insulin analogues, nor between GLP-1 analogues.

**Conclusion:** REE decreased early on insulin therapy whereas it is not affected by GLP-1 analogues. These different effects on REE probably contribute to the opposite weight changes with these treatments. Our future work will be to assess if early changes in REE with bed-time insulin or GLP-1 analogues predict long-term weight evolution.

## 711

**Chronic exenatide infusion increases insulin sensitivity, decreases insulin secretion and stimulates islet cell proliferation in partially pancreatectomised baboons**A.M. Paez<sup>1</sup>, S. Kamath<sup>1</sup>, F. Casiraghi<sup>1</sup>, A. Davalli<sup>2</sup>, G. Abrahamian<sup>1</sup>, A. Ricotti<sup>1</sup>, S. La Rosa<sup>3</sup>, A. Commuzzie<sup>4</sup>, A. Marando<sup>3</sup>, G. Finzi<sup>3</sup>, E. Dick<sup>4</sup>, R. De Fronzo<sup>1</sup>, G. Halff<sup>1</sup>, F. Folli<sup>1</sup>;<sup>1</sup>UTHSCSA, San Antonio, USA, <sup>2</sup>SRI, Milano, Italy, <sup>3</sup>Circolo Hosp, Varese, Italy, <sup>4</sup>TBRI, San Antonio, USA.

**Background and aims:** Baboons are an interesting non-human primate model of insulin resistance and T2DM due to genetic and pathophysiologic similarities with humans. We studied the effects of a continuous IV exenatide (EXE) infusion after partial pancreatectomy (PP), on in-vivo glucose metabolism, α-β-δ cell mass and islet function in baboons.

**Materials and methods:** Two study groups: 1) EXE (n=12 F); 2) saline (SAL) (n=12 F). At baseline, all animals had a 2-step hyperglycemic clamp (1st step raise blood glucose +125mg/dL above fasting glucose; 2nd step: +225 mg/dL above fasting glucose) followed by an Arginine bolus (0.5g/kg). After completion of the hyperglycemic clamp, both groups underwent PP (the tail, ~30% of pancreas, was excised). Afterwards, a continuous EXE (0.014 µg/kg/h) or normal SAL infusion was started for 13 weeks. After 72 h EXE washout, clamps were repeated followed by euthanasia and removal of pancreas (head-body, ~70% of pancreas).

**Results:** Insulin sensitivity (M/I) increased by 41%, insulin secretion (ISR) decreased by 25% and β cell function=Disposition Index (ISR\*M/I) increased 50% after EXE, while they were unchanged in SAL. Morphometry by CAST, was used to quantify Islet's and immunostained α, β, δ cells' volume, expressed as % of total pancreas. PP SAL baboons had 42% decrease in islets in head-body vs tail (3.4±0.4 vs 6 ±0.6, p= 0.01), 43% decrease in β-cells (3.2±0.2 vs 5.5±0.5, p=0.003), 74% decrease in α- cells (0.6±0.2 vs 2.4±0.5, p=0.003) and 53% decrease in δ-cells (0.3±0.01 vs 0.7±0.1, p=0.02). After EXE there was only a 5% decrease in islets in head-body vs tail (6.2±0.9 vs 6.5±0.8, p= NS), 17% decrease in β cells (4.7±0.5 vs 5.6±0.8, p=NS), 21% decrease in α cells (1.6±0.5

vs 2.1±0.4, p=NS) and 15% increase in δ cells (0.8±0.01 vs 0.7±0.2, p=NS). EXE increased islet mass vs SAL in head-body (6.2±0.9 vs 3.4±0.4, p=0.01) suggesting that proliferation was involved. Proliferation and apoptosis were expressed as % of cells counted. MIB-1 staining, a cell proliferation marker, demonstrated proliferation after EXE, comparing baseline (tail) vs end of study (head-body) (0.07+ 0.03 vs 0.43+ 0.06, p=0.0001). There was also an increase in proliferation when comparing the EXE end of study vs SAL end of study (0.43+ 0.06 vs 0.07 + 0.04, p=0.0001). There were no differences between SAL basal vs end of study (0.07+ 0.04 vs 0.07 + 0.04, p=NS) or basal SAL vs basal EXE (0.07+ 0.04 vs 0.07 + 0.03, p=NS). Furthermore, EXE slightly attenuated post-PP apoptosis by M30 staining, tail vs head-body (1.58+ 0.58 vs 2.58 + 0.47, p=NS) as compared with SAL group which had significantly increased post-PP apoptosis, tail vs head-body (0.52 + 0.21 vs 1.75 + 0.55, p=0.05). Electron microscopy of SAL end of study pancreas demonstrated endoplasmic reticulum stress, degranulation and nuclear alterations consistent with apoptosis in β-cells. These changes were absent after EXE treatment.

**Conclusion:** Chronic IV EXE improves insulin sensitivity and disposition index, while decreasing glucose-arginine stimulated insulin secretion (a condition of β-cell rest). Furthermore, EXE stimulates proliferation and attenuates apoptosis of α-β-δ cells, thereby increasing islet of Langerhans mass in non-human primate pancreas, *in vivo*.

**A high fat diet during pregnancy and lactation reverses the protection from obesity in Gpr<sup>-/-</sup> mice via altered hypothalamic and peripheral gene expression in offspring**F. Keyhani Nejad<sup>1,2</sup>, F. Isken<sup>1,2</sup>, M. Osterhoff<sup>1,2</sup>, A.F.H. Pfeiffer<sup>1,2</sup>, M. Kruse<sup>1</sup>;<sup>1</sup>Dept. of Clinical Nutrition, German Institute of Human Nutrition, Nuthetal, <sup>2</sup>Department for Endocrinology, Diabetes and Nutrition, Charité – University of Medicine, Berlin, Germany.

**Background and aims:** A high fat diet (HFD) consumed during gestation (IU) and lactation (L) predisposes offspring to develop obesity and insulin resistance in adulthood. Inhibition of Glucose -dependent insulintropic polypeptide (GIP) signaling in GIP receptor knock out mice (Gipr<sup>-/-</sup>) leads to protection from HFD induced obesity. Recently, we have shown that Gipr<sup>-/-</sup> mice which were exposed to HFD during IU/L and in early adulthood are no longer protected from diet induced obesity, had a decreased glucose tolerance, but showed reduced cumulative energy intake. Hypothalamic insulin sensitivity is necessary for balanced food intake and might also affect peripheral energy expenditure. We followed up on these observations and hypothesized that the potential programming effects of IU/L HF consumption on adiposity and food intake in Gipr<sup>-/-</sup> mice are due to altered hypothalamic insulin sensitivity and decreased peripheral fat oxidation.

**Materials and methods:** Female GIP receptor heterozygous (Gipr<sup>+/-</sup>) mice were fed either a HF (60%, fat) or control (C, 10% fat) diet for 2 weeks prior to mating with Gipr<sup>+/-</sup> male mice and during IU/L. Male Gipr<sup>-/-</sup> and wild type (WT) offspring were kept on normal chow for 22 weeks after weaning. At the age of 25 weeks, mice were fed the same HFD used during the IU/L for 20 weeks. This resulted into Gipr<sup>-/-</sup> which were exposed to either a C (KO Ciu-HF) or a HFD (KO HFiu-HF) during IU/L and a HFD later in adulthood. WT mice fed a control diet during IU/L and a HFD in adulthood served as controls (WT Ciu-HF). Body weight (BW) and food intake (FI) were recorded weekly. At the age of 45 weeks, gene expression levels of hypothalamic phosphatidylinositol 3-kinase (PI3K) and fatty acid oxidation in muscle were analyzed by quantitative RT-PCR and adipocyte sizes were analyzed using H&E staining histology.

**Results:** BW and FI between WT and Gipr<sup>-/-</sup> mice were not significantly different during the first 22 weeks. By re-exposure to HF at 25 weeks of age, body fat content significantly increased in KO HFiu-HF compared to KO Ciu-HF (22.6 ± 2.5 g vs. 19.5 ± 0.8 g, respectively; p<0.05). KO HFiu-HF had significantly increased adipocytes compared to KO Ciu-HF (p<0.005). Re-introduction to HF significantly reduced cumulative energy intake in KO HFiu-HF and WT Ciu-HF mice compared to KO Ciu-HF (37.7 ± 0.7 and 38.6 ± 1.6 vs. 43.5 ± 1.5, respectively; all p<0.01). In KO Ciu-HF hypothalamic gene expression of PI3K subunit p85α was 22% down regulated compared to WT Ciu-HF mice (p<0.01) and back up regulated 1.27 fold in KO HFiu-HF compared to KO Ciu-HF (P< 0.05). Gene expression levels of PPARα and PGC1α, the key enzymes of fatty acid oxidation, were massively increased in KO Ciu-HF compared to WT Ciu-HF mice (2.45-fold for PPARα and 1.85-fold for PGC1α, both P<0.01), but then down regulated 1.9-fold for PGC1α and 2.4-fold for PPARα in KO HFiu-HF compared to KO Ciu-HF (p<0.05) in muscle.

**Conclusion:** We conclude that consuming a high fat diet during pregnancy and lactation is able to reverse the favorable phenotype of inhibition of GIP signaling by decreasing central insulin sensitivity via up-regulation of regulatory subunit of PI3K and reducing the expression of key genes in fatty acid oxidation, which could account for the reduced body weight despite an increase in food intake.

### Removal of L- and alpha cells improves oral glucose tolerance and accelerates diphtheria toxin induced weight loss in diabetic mice

J. Pedersen, S.M. Jørgensen, A. Plamboeck, J.A. Windeløv, J.J. Holst; Novo Nordisk Foundation Center for Basic Metabolic Research, Dept. Biomedical Sciences, University of Copenhagen, Denmark.

**Background and aims:** Proglucagon is a prohormone encoded by the *Glucagon* gene (*Gcg*) and several proglucagon derived peptides play a role in the regulation of metabolism. Pancreas specific post-translational processing produces glucagon, whereas intestinal and neuronal specific post-translational processing produces oxyntomodulin, glucagon-like peptide 1 and glucagon-like peptide 2. In both rodents and humans dysregulation of the secretion of proglucagon derived peptide hormones leads to impaired regulation of metabolism. The aim of the present study was to evaluate the consequences of removal of *Gcg* expressing cells in diabetic mice on glucose tolerance and bodyweight.

**Materials and methods:** The diphtheria toxin receptor *Gcg* cellular knock-out mouse (TgN(GCG.DTR)) allowed us to study the acute loss of proglucagon derived peptide hormones on glucose metabolism in mice metabolically stressed by high fat diet (60% of energy from fat) and single injection with low dose (100mg/kg) streptozotocin.

**Results:** Intraperitoneal injection with diphtheria toxin reduced immunoreactive glucagon content in tissue extract isolated from terminal ileum or pancreas with 50 and 10 fold respectively. Ablation of *Gcg* expressing cells in STZ injected mice placed on high fat diet improved oral glucose tolerance,  $AUC_{0-150min}$   $3744 \pm 350 \text{ mmol} \cdot \text{l}^{-1} \cdot \text{min}$  to  $2560 \pm 202 \text{ mmol} \cdot \text{l}^{-1} \cdot \text{min}$  ( $p < 0.001$ ). Removal of *Gcg* expressing cells, accelerated the weight loss following DT-injections  $1.21 \pm 0.19 \text{ g} \cdot \text{d}^{-1}$  vs  $0.65 \pm 0.10 \text{ g} \cdot \text{d}^{-1}$  ( $p < 0.02$ ), mostly explained by a loss of fat mass.

**Conclusion:** Our newly introduced genetically modified mouse allows the study of combined L- and  $\alpha$ -cell depletion in an already obese and diabetic mouse. Our findings underscore the diabetogenic effects of the unopposed  $\alpha$ -cells and antidiabetic effects of lack of  $\alpha$ -cells in models of type 2 diabetes. Surprisingly, our findings suggest an intact  $\alpha$ -cells mass is essential for body weight maintenance.

### Improvement of basal hyperglycaemia in diabetic GK rat after chronic treatment by liraglutide is associated with reduced alpha cell mass

J. Movassat<sup>1</sup>, A. Ilias<sup>1</sup>, S. Madani<sup>2</sup>, M. Alawieh<sup>1</sup>, D. Bailbé<sup>1</sup>, B. Portha<sup>1</sup>;

<sup>1</sup>University Paris Diderot, Paris, <sup>2</sup>Novo Nordisk, La Défense, France.

**Background and aims:** GLP-1 and its analogues have received much attention as a possible new treatment for type 2 diabetes. GLP-1 stimulates insulin secretion and biosynthesis and inhibits glucagon release. While GLP-1-induced beta cell proliferation and survival effects are well documented, there is a shortage of information on whether GLP-1 analogues modulate the rodent alpha-cell mass (ACM) under conditions of chronic T2DM. Our aim was to investigate, in the Goto-Kakizaki rat, a model of T2DM, the effects of a chronic treatment by the GLP1 analogue Liraglutide (Lira), 1/ on the beta-cell mass, the body weight (BW) gain, basal hyperglycemia and the glucose-induced insulin secretion in vivo; 2/ on basal plasma glucagon and on the (ACM) within the pancreas.

**Materials and methods:** Eight weeks old male GK rats were treated once daily (5:00 pm) subcutaneously at the dose of 0.2mg/kg BW, during 30 days (Lira group). Another group of rats was treated with saline solution (control group). The control group was pair-fed by adjusting their food intake at the equivalent amount of food taken by the rats of the Lira group. BW, food and water intake were measured daily. The basal glycemia was measured twice a week. Basal plasma insulin and glucagon were measured by RIA at days 0, 15 and 30 of the treatment. The glucose-induced insulin secretion in vivo was determined during an OGTT.

**Results:** Our results show that a 30 days Lira treatment improves the basal hyperglycemia of the diabetic GK rat (35% decrease). Importantly this was not associated with changes in basal or glucose-induced insulin secretion. However Lira treatment significantly reduced basal plasma glucagon (by 50 %) and surprisingly this was related with a significant decrease in the ACM (by 40%), whereas the beta cell mass was not affected. Experiments aimed to define the mechanisms for down-regulation of the ACM in response to Lira are in progress.

**Conclusion:** In conclusion, our data suggest that the beneficial effect of chronic Lira treatment on the hyperglycemic GK rat is due to the decrease of glucagon secretion which could in part be related to a decreased number of alpha-cells within the pancreas. Importantly, these Lira effects were observed independently of the Lira-induced diminution of food intake.

### GLP-1 analogue protect against inflammatory stress induced by diet and Acrp30 knockdown by inhibiting c-JNK

L. Xiaohu<sup>1,2</sup>, L. Li<sup>1,2</sup>, L. Zhang<sup>3</sup>, G. Yang<sup>3</sup>;

<sup>1</sup>College of Laboratory Medicine, <sup>2</sup>Key Laboratory of Laboratory Medical Diagnostics in Ministry of Education, <sup>3</sup>The Second Affiliated Hospital, Chongqing Medical University, China.

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD), one of the most common chronic liver diseases, includes a spectrum ranging from simple steatosis to steatohepatitis and cirrhosis. Liraglutide, a Glucagon-like peptide-1 (GLP-1) analogue with 97% sequence identity to human GLP-1, increases insulin secretion and insulin sensitivity. Its effect on nonalcoholic fatty liver disease (NAFLD) remains poorly understood. Recently, it has been reported that GLP-1 directly reduced hepatic lipogenesis via the cAMP/AMPK pathway in DPP4-deficient rats [12]. More recently, some studies have implied that exendin-4 could prevent TNF- $\alpha$  induced JNK phosphorylation in beta cell [13] and decrease inflammatory gene expression in isolated human pancreatic islets. In this study, we examined whether liraglutide can protect against inflammatory stress by inhibiting activation of c-Jun N-terminal protein kinase (JNK).

**Materials and methods:** ApoE KO and adiponectin (Acrp30) knockdown mice fed a high-fat diet (HFD) were treated with liraglutide (10 mg/kg, twice daily) for 8 weeks. Hyperinsulinemic-euglycemic clamp studies were performed. Glucose rates of appearance (GRa) were determined with 3-[<sup>3</sup>H] glucose. Whole body GRa and glucose uptake (GR<sub>d</sub>) were calculated using the non-steady-state equation. Liver tissue was procured for histological examination, real-time RT-PCR and western blot analysis.

**Results:** The combination of HFD, Acrp30 knockdown and ApoE deficiency had additive effects on the development of insulin resistance (IR) and NAFLD. Administration of liraglutide prevented the development of HFD

and hypoadiponectinemia-induced IR and NAFLD in this model. Liraglutide also attenuated the expression of proinflammatory cytokines, including TNF- $\alpha$  and NF- $\kappa$ B, and the expression of two lipogenesis-related genes, Acetyl-CoA Carboxylase (ACC) and fatty acid synthase (FAS). These changes were accompanied by elevated plasma of Acrp30, increased Acrp30 mRNA, AMP Kinase phosphorylation, decreased mitogen-activated protein kinase 4 (MKK4) mRNA expression and JNK phosphorylation.

**Conclusion:** Our study demonstrated that liraglutide improved insulin sensitivity and low-grade inflammatory stress induced by HFD and hypoadiponectinemia and inhibited MKK4/JNK activation. The inhibitory effects of liraglutide on low-grade inflammatory stress and IR might be due to inhibition of JNK activation. Therefore, liraglutide may play a dual role in regulating insulin sensitivity and inflammatory responses via MKK4/JNK signaling. Thus, we believe that liraglutide or similar long-acting analogs may be useful to improve or prevent NAFLD. This may contribute to the beneficial effects of liraglutide on decreasing hepatic fat accumulation and improving insulin sensitivity in patients with type 2 diabetes.

### Glucosensing responses of preproglucagon neurons in the nucleus tractus solitarius in vitro

S. Trapp<sup>1</sup>, K. Hisadome<sup>1</sup>, F. Reimann<sup>2</sup>, F.M. Gribble<sup>2</sup>;

<sup>1</sup>Surgery and Cancer, Imperial College London, London, <sup>2</sup>Cambridge Institute for Medical Research, University of Cambridge, UK.

**Background and aims:** Glucagon-Like Peptide-1 (GLP-1) is an incretin released from enteroendocrine L-cells postprandially and has glucoregulatory and satiety effects. GLP-1 is also produced as a neuropeptide by preproglucagon (PPG) neurons, found mainly in the nucleus tractus solitarius (NTS). We have previously shown that these neurons enhance their electrical activity in response to satiety peptides such as leptin and CCK, but it is currently unknown whether PPG neurons respond electrically to changes in local glucose availability, and thus might be involved in glucoprivic feeding responses.

**Materials and methods:** Adult transgenic mice expressing yellow fluorescent protein (YFP) under PPG promoter control were kept at a 12h light/dark cycle with ad libitum access to food and water. Coronal brainstem slices (200  $\mu$ m thick) containing the caudal NTS were obtained from these mice either at the beginning of the light period or at the beginning of the dark period, and maintained at 32°C in artificial cerebrospinal fluid (ACSF). Current- and voltage-clamp recordings were carried out on individual PPG neurons identified by their YFP fluorescence. ACSF Glucose concentrations were altered between 0.1 mM and 10 mM in order to elicit a glucosensing response.

**Results:** 48% of PPG cells from slices obtained during the light period were inhibited by glucose (GI): firing rate was  $3.9 \pm 1.5$  Hz,  $3.1 \pm 0.9$  Hz and  $2.0 \pm 0.7$  Hz ( $n=11$ ), in 0.1, 2 and 10 mM glucose, respectively. Another 11 cells showed no change in firing rate and 1 cell was excited by glucose (GE). In contrast, out of 29 PPG cells from slices obtained during the dark phase, 20 neurons were GE, with a firing rate of  $1.2 \pm 0.2$  Hz and  $1.9 \pm 0.3$  Hz in 1 mM and 10 mM glucose, respectively. 8 cells showed no change in firing rate and 1 cell was GI. Single-cell RT-PCR revealed that PPG neurons do not express glucokinase ( $n=18$ ) thus ruling out metabolic glucosensing equivalent to pancreatic  $\beta$ -cells. Finally, to test whether a Na<sup>+</sup>-dependent glucose transporter (SGLT) is involved in the GE response, PPG neurons were preincubated with the SGLT blocker phloridzin (10  $\mu$ M;  $n=7$ ) for 5 min and subsequently exposed to 10 mM glucose in the presence of phloridzin. This attenuated the increase in firing rate seen with 10 mM glucose by  $60 \pm 20\%$ .

**Conclusion:** A substantial proportion of NTS PPG neurons respond to changes in glucose availability. During the dark phase when mice are most active most PPG neurons show a GE response, consistent with a role of GLP-1 as satiety signal. This response appears to involve SGLT as previously found in GLP-1 releasing enteroendocrine cells. The circadian regulation of this response remains to be investigated. We hypothesise that PPG neurons are central to integrating peripheral satiety signals and brain energy status into a feeding response. Further studies should target these neurons *in vivo* to test this hypothesis.

## 717

### RANTES reduces glucose-dependent GLP-1 secretion from intestinal L- cells

R. Pais, T. Zietek, H. Hauner, H. Daniel, T. Skurk;  
Technical University Munich, Freising, Germany.

**Background and aims:** Obesity is characterized by an increased production and secretion of pro-inflammatory factors such as acute phase proteins, cytokines and chemokines. The constitutively increased circulating levels of these factors are considered to contribute to a low grade inflammatory condition which may promote the co-morbidities of obesity like diabetes mellitus type 2. GLP-1 is a peptide hormone secreted from intestinal L-cells upon nutrient ingestion. It not only promotes insulin secretion from  $\beta$ -cells but also appears to protect from  $\beta$ -cell loss. GLP-1 secretory responses are impaired in obese and diabetic humans. RANTES is a small protein of 68 amino acids belonging to the C-C subfamily of chemokines. It promotes the recruitment and activation of inflammatory cells such as monocytes, lymphocytes, mast cells, and eosinophils and exerts its biological effects by binding to specific receptors that belong to the seven-transmembrane G-protein-coupled receptor (GPCR) family, namely CCR1, CCR3 and CCR5. RANTES is secreted from platelets, macrophages, eosinophils and fibroblasts and was only very recently described as a new adipokine. Its secretion positively correlates with adipocyte size and is gender specific and its serum levels and gene expression levels in white adipose tissue are higher in obese than in lean and higher in subjects with impaired glucose tolerance and type 2 diabetes. The aims of the present work were to 1) determine the presence of RANTES receptors, in the intestinal epithelium and in NCI-H716 cells, (2) to test the effects of recombinant RANTES on glucose stimulated GLP-1 secretion in vitro, and (3) to confirm the effects on glucose-dependent GLP-1 secretion in an in vivo model employing C57 BL/6 mice.

**Materials and methods:** To study this, we used the NCI-H716 cell line, a human intestinal GLP-1 secreting cell line and applied RANTES and measured GLP-1 output. We used techniques like RT-PCR, western blot and immunofluorescence to identify receptors for RANTES on the L-cell. We measured intracellular calcium and cAMP as downstream signaling pathways involved. Also we administered RANTES to mice and measured GLP-1 in plasma after a glucose bolus.

**Results and conclusion:** We demonstrate that RANTES reduces glucose stimulated GLP-1 secretion from in vitro cultures of human enteroendocrine cells with Met-RANTES (RANTES receptor antagonist) blocking this effect. We identified CCR1 at message and protein level in the NCI-H716 cells and mouse intestinal L-cells. RANTES reduced accumulation of cAMP in the NCI-H716 cells and also reduced glucose induced increase in intracellular calcium. Moreover, administration of RANTES in mice revealed reduced plasma GLP-1 and GLP-2 levels after an oral glucose load as well as impaired insulin secretion. These data suggests that elevated RANTES blood levels as found in obese individuals may cause the altered GLP-1 secretory response and identifies the RANTES-receptors as potential targets in diabetes therapy.

### Development of <sup>125</sup>I-labeled exendin probe targeting GLP-1 receptors for detecting insulinoma cells

H. Fujimoto<sup>1</sup>, K. Toyoda<sup>1</sup>, H. Kimura<sup>2</sup>, Y. Ogawa<sup>2</sup>, H. Mstsuda<sup>2,3</sup>, M. Takagi<sup>3</sup>, A. Kon<sup>3</sup>, M. Ono<sup>2</sup>, H. Saji<sup>2</sup>, N. Inagaki<sup>1</sup>;

<sup>1</sup>Department of Diabetes and Clinical Nutrition, Graduate School of Medicine, Kyoto University, <sup>2</sup>Department of Patho-Functional Bioanalysis, Graduate School of Pharmaceutical Science, Kyoto University, <sup>3</sup>Arkray, Inc, Kyoto, Japan.

**Background and aims:** Among pancreatic neuroendocrine tumors, insulinoma is the most common tumor. About 90% of insulinomas is typically small size (<2 cm), therefore imaging methods need to be high sensitivity and specificity to the target for detecting such small tumors. It has been reported that insulinoma frequently expressed glucagon-like peptide-1 receptor (GLP-1R) with high density. Thus, a radiolabeled compound bound to GLP-1R has been expected to be the useful tool for imaging insulinoma. In this study, we designed and synthesized [<sup>125</sup>I]-N<sup>6</sup>-(3-[(<sup>125</sup>I]iodobenzoyl)lysine<sup>12</sup>]-Exendin(9-39)-NH<sub>2</sub> ([<sup>125</sup>I]IB12-Ex(9-39)) targeting GLP-1R on insulinoma cells, and evaluated its utility as a probe for SPECT imaging of insulinoma in the mouse model.

**Materials and methods:** For synthesizing [<sup>125</sup>I]IB12-Ex(9-39), the lysine residue of exendin(9-39) at 12 was labeled with [<sup>125</sup>I]. The binding affinity of

IB12-Ex(9-39) to human GLP-1R was evaluated by competitive binding assay using the prepared cell membranes. For assessment of the *in vivo* organ selectivity, biodistribution studies were conducted with INS-1-xenografted mice at 15, 30, 60, 120, and 360 min after [ $^{125}$ I]IB12-Ex(9-39) injection. SPECT imaging was performed 30min after injection of [ $^{125}$ I]IB12-Ex(9-39) into the INS-1-xenografted mice. In addition, stability of [ $^{125}$ I]IB12-Ex(9-39) *in vivo* was evaluated by analysis of the extracted tumor homogenate with reverse phase HPLC analysis.

**Results:** The results of binding assay analysis showed competitive inhibition of IB12-Ex(9-39) binding by non-radioactive GLP-1 and its IC<sub>50</sub> was 1.6 nM. The *in vivo* biodistribution of [ $^{125}$ I]IB-Ex(9-39) in INS-1-xenografted mice showed a high uptake in the tumor (12% dose/g at 6 h) and the ratio of radioactivity at 6 h in tumor-to-blood, tumor-to-muscle, tumor-to-pancreas were 30.0, 75.0, and 2.4, respectively. SPECT imaging studies revealed the remarkable accumulation of radioactivities at the site of INS-1 tumor (Arrow in the Figure). In addition, [ $^{125}$ I]IB12-Ex(9-39) showed high stability *in vivo*.

**Conclusion:** It was possible to detect the small tumor of insulinoma by using [ $^{125}$ I]IB12-Ex(9-39) as the probe for SPECT. Probes targeting GLP-1R would be useful for detecting such GLP-1R expressing tumors.

## PS 054 Beneficial effect of bariatric surgery and weight loss

### One year change in metabolic syndrome components in the Helping Evaluate Reduction in Obesity (HERO) study

J. Dixon<sup>1,2</sup>, T. Okerson<sup>3</sup>, C. Burk<sup>4</sup>, R. Shi<sup>3</sup>, D. Ng-Mak<sup>3</sup>, D. Globe<sup>3</sup>, N.A. Dreyer<sup>5</sup>;

<sup>1</sup>Baker IDI Heart and Diabetes Institute, Melbourne, Australia, <sup>2</sup>Monash University, Melbourne, Australia, <sup>3</sup>Allergan, Inc., Irvine, USA, <sup>4</sup>Health Outcomes Consultant, Laguna Beach, USA, <sup>5</sup>Outcome, a Quintiles Company, Cambridge, USA.

**Background and aims:** Few studies have assessed effect of weight loss following LAP-BAND® AP adjustable gastric banding (LAGB) on the change of Metabolic Syndrome (MeS) components in obese patients. No study has compared regional differences in components of MeS after banding.

**Materials and methods:** Subjects enrolled in the HERO 5-year prospective study of LAGB from the United States (US), Canada (CA), Australia (AU), and Europe (EU) and who had baseline (BL) as well as 1 Year (1 YR) data to determine MeS status, were included in this analysis (834/1,123). BL and 1 YR rates of MeS components were assessed and compared by regions using the NCEP ATP III MeS definition using Chi-square.

**Results:** Table 1 shows prevalence of MeS and its components at BL and 1 YR by regions. In general, reduced high density lipids (HDL) and raised blood pressure were the most prevalent components of MeS in addition to the waistline circumference that qualified patients for MeS at baseline and 1 YR. Of these, more patients were from the US and CA/AU than the EU at baseline ( $p < 0.05$ ) and 1 Yr ( $p > 0.05$ ). At 1 YR, median weight change was -16.5% (mean value was -16.9%) ( $p < 0.001$ ). Additionally, there was a decrease in MeS as well as a decrease in each of the components compared to BL ( $p < 0.05$ ) for the overall study group and for each region by 1 YR ( $p < 0.05$ ).

**Conclusion:** LAGB was associated with significant decreases in MeS and its components at 1 YR across all regions. Adjustable gastric banding may play a role in treatment of obese patients with MeS. Further long-term follow-up of these patients will help to determine durability of these results.

Table 1. Prevalence of Metabolic Syndrome and its Components in HERO study at baseline and Month 12 by Regions

	Metabolic Syndrome	Raised triglycerides or treatment for lipid abnormality	Reduced HDL or treatment for lipid abnormality	Raised blood pressure or treatment for hypertension	Raised fasting plasma glucose or treatment for Type 2 diabetes
Baseline					
Overall (N=834)	599 (71.8%)	361 (43.3%)	584 (70.0%)	609 (73.0%)	360 (43.2%)
US (N=539)	402 (74.6%)	228 (42.3%)	397 (73.7%)	394 (73.1%)	248 (46.0%)
CA/AU (N=125)	92 (73.6%)	66 (52.8%)	76 (60.8%)	108 (86.4%)	59 (47.2%)
EU (N=170)	105 (61.8%)	67 (39.4%)	111 (65.3%)	107 (62.9%)	53 (31.2%)
1 year*					
Overall (N=834)	356 (42.7%)	240 (28.8%)	355 (42.6%)	462 (55.4%)	221 (26.5%)
US (N=539)	232 (43.0%)	151 (28.0%)	241 (44.7%)	279 (51.8%)	145 (26.9%)
CA/AU (N=125)	59 (47.2%)	41 (32.8%)	51 (40.8%)	89 (71.2%)	37 (29.6%)
EU (N=170)	65 (38.2%)	48 (28.2%)	63 (37.1%)	94 (55.3%)	39 (22.9%)

\* $p < 0.05$  for all compared changes from baseline in MeS and each component for overall study and by regions.

Clinical Trial Registration Number: NCT00953173

### One year diabetes remission and improvement in the HERO (helping evaluate reduction in obesity) study

D.S. Ng-Mak<sup>1</sup>, M. Torre<sup>2</sup>, J. Dixon<sup>3,4</sup>, T. Okerson<sup>1</sup>, R. Shi<sup>1</sup>, D. Globe<sup>1</sup>;

<sup>1</sup>Allergan, Inc., Irvine, USA, <sup>2</sup>Allergan Medical, Goleta, USA, <sup>3</sup>Baker IDI Heart and Diabetes Institute, Melbourne, Australia, <sup>4</sup>Monash University, Melbourne, Australia.

**Background and aims:** Remission or improvement of type 2 diabetes (T2D) after gastric bypass surgery has been shown to be related to the duration of diabetes, the severity of disease, and amount of weight loss (or weight regain). However, few studies reported the factors related to diabetes remission after adjustable gastric banding (AGB). The overall objective of the HERO study is to examine the clinical effectiveness and safety of LAP-BAND® AP AGB over five years. This analysis seeks to identify factors associated with diabetes remission and improvement 1 year after AGB.

**Materials and methods:** The HERO study enrolled 1,123 subjects, 300 of whom reported either having a history of T2D or taking an anti-diabetic medication at baseline (BL); these were defined as having T2D at BL. The analysis sample included 199 subjects who provided complete BL and 1 year follow up data. Using the American Association of Clinical Endocrinologists (AACE) guidelines for T2D definition, diabetes remission was defined as HbA<sub>1c</sub> level of  $\leq 6.5\%$  and no anti-diabetic medication usage at 1 year. Diabetes improvement was defined as HbA<sub>1c</sub> level of  $\leq 6.5\%$ . Multivariate logistic regression was used to examine factors associated with remission and improvement at 1 year, controlling for region (US vs ex-US) and years of diabetes duration.

**Results:** Remission and improvement of T2D at 1 year were 39% and 64%, respectively. Baseline weight (kgs) was similar between those with remission (128.0), improvement (129.0) and no change (131.0). Those with remission or improvement had shorter diabetes duration in years than those without change (5.5 and 5.8 vs 8.6 respectively ( $p<.01$ )). At 1 year, both remission and improvement groups had significantly greater percent weight loss (%WL) than those without change (19.2%, 17.4% and 12.2%, respectively ( $p<.001$ )). Multivariate analysis showed that %WL (OR=1.11,  $p<.001$ ) was the most significant factor in predicting T2D remission at 1 year. Controlling for region (OR=2.6,  $p=.045$ ) and diabetes duration (OR=.89,  $p=.003$ ), subjects with 20%WL were 8.6 times more likely to have diabetes remission at 1 year. Similarly, multivariate analysis showed that %WL (OR=1.12,  $p<.001$ ) was the most significant factor in predicting T2D improvement at 1 year. Controlling for diabetes duration (OR=.86,  $p<.001$ ), subjects with 20%WL were 9.6 times more likely to have diabetes improvement at 1 year. No regional difference was observed in the prediction of diabetes improvement at 1 year.

**Conclusion:** AGB was associated with significant weight loss and resultant diabetes remission and improvement over 1 year. Our results are similar to the findings reported with RYGB, such that earlier intervention with bariatric surgery, and more specifically AGB, is more likely to result in diabetes remission. Future research is needed to investigate the interrelationship between beta-cell function, improved insulin sensitivity and AGB-facilitated weight loss on diabetes remission/improvement.

Clinical Trial Registration Number: NCT00953173

## 721

### Sustained reductions in weight and HbA<sub>1c</sub> with dapagliflozin: long-term results from phase III clinical studies in type 2 diabetes

C.J. Bailey<sup>1</sup>, J. Wilding<sup>2</sup>, M.A. Nauck<sup>3</sup>, E. Ferrannini<sup>4</sup>, A.A. Ptaszynska<sup>5</sup>, A.M. Apanovitch<sup>5</sup>, J. Sugg<sup>6</sup>, S.J. Parikh<sup>6</sup>

<sup>1</sup>Aston University, School of Life and Health Sciences, Birmingham, UK, <sup>2</sup>University Hospital Aintree, Liverpool, UK, <sup>3</sup>Diabeteszentrum Bad Lauterberg, Germany, <sup>4</sup>University of Pisa School of Medicine, Italy, <sup>5</sup>Bristol-Myers Squibb, Princeton, USA, <sup>6</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin (DAPA), a selective inhibitor of sodium glucose co-transporter 2 (SGLT2), reduces plasma glucose independently of insulin secretion or action, by increasing urinary glucose excretion. In clinical trials up to 2 years, DAPA was associated with a reduction in total body weight (TBW), a key management goal in type 2 diabetes (T2D). This analysis reports TBW and HbA<sub>1c</sub> from four phase III clinical trials of DAPA, in predominantly overweight/obese patients with T2D, with different treatment backgrounds, and at different stages of disease.

**Materials and methods:** The effect of DAPA (10 mg/d) on TBW and HbA<sub>1c</sub> was assessed in four randomised, double-blind, placebo- (PBO) or comparator-controlled trials: DAPA monotherapy vs PBO (102 wks); DAPA add-on to metformin (MET) [DAPA+MET] vs PBO+MET (102 wks); DAPA+MET vs glipizide (GLIP)+MET (104 wks); DAPA+insulin (INS) [DAPA+INS] vs PBO+INS (104 wks).

**Results:** In all DAPA groups, the significant reductions in TBW and HbA<sub>1c</sub> observed at the end of the 24-wk short-term study were sustained for up to 2 years (Figure). At 102/104 wks, DAPA was associated with clinically meaningful reductions in TBW from baseline (BL) in each study (range: -1.74 to -4.05 kg). In contrast, over the same time period, weight gain from BL was observed in the PBO+MET (+1.36 kg), GLIP+MET (+1.36 kg) and PBO+INS (+0.91 kg) groups. PBO- or comparator-corrected adjusted mean reductions in TBW were in the range -2.41 to -5.06 kg. In addition, DAPA produced clinically meaningful reductions in HbA<sub>1c</sub> from BL (range: -0.32 to -0.78%), with PBO- or comparator-corrected adjusted mean reductions in HbA<sub>1c</sub> in the range -0.18 to -0.80%. In the DAPA groups, systolic blood pressure was either reduced or maintained in all studies (mean change from BL; range: -0.3 to -5.9 mmHg). Urinary glucose/creatinine ratio was elevated and maintained in all

studies, supporting the long-term efficacy of DAPA as an SGLT2 inhibitor. Adverse events were generally balanced across the groups. DAPA (10 mg/d) was not associated with a higher risk of hypoglycaemia. Events suggestive of genital and urinary tract infection were greater with DAPA. Infections occurred more often in the first 24 wks, were mostly mild to moderate in severity, managed by standard interventions, and without serious clinical consequences. **Conclusion:** In populations of overweight/obese patients with T2D, treated across the typical course of the disease, DAPA administered as monotherapy or in combination with MET or INS was associated with sustained decreases in both TBW and HbA<sub>1c</sub> over 2 years.

<sup>a</sup>Excludes data after start of rescue medication or INS up-titration.

<sup>a</sup>mean at baseline; <sup>b</sup>+MET after 24 wks. Error bars = 95% confidence interval (CI).

### Adipose tissue TCF7L2 splicing is regulated by weight loss and associates with glucose and fatty acid metabolism

D. Kaminska<sup>1,2</sup>, T. Kuulasmaa<sup>3</sup>, S. Venesmaa<sup>3</sup>, P. Käkälä<sup>3</sup>, M. Vaitinen<sup>1</sup>, L. Pulkkinen<sup>1</sup>, M. Pääkkönen<sup>3</sup>, H. Gylling<sup>1</sup>, M. Laakso<sup>2</sup>, J. Pihlajamäki<sup>1,2</sup>

<sup>1</sup>Institute of Public Health and Clinical Nutrition, <sup>2</sup>Department of Medicine,

<sup>3</sup>Department of Surgery, University of Eastern Finland and Kuopio University Hospital, Finland.

**Background and aims:** We have recently published, that expression of several genes regulating alternative splicing is reduced in liver and muscle of obese individuals. TCF7L2 consists of 18 exons and is subject to extensive alternative splicing in different human tissues. We investigated the effects of obesity surgery induced weight loss on TCF7L2 alternative splicing in adipose tissue and liver. Furthermore, we determined the association of TCF7L2 splicing with the levels of plasma glucose and serum free fatty acids (FFAs) in three independent studies (n=216).

**Materials and methods:** Alternative splicing in adipose tissue was investigated using PCR-capillary electrophoresis on samples extracted from subcu-

taneous and visceral adipose tissue of 95 participants of the ongoing Kuopio Obesity Surgery Study (KOBS). The association between alternatively spliced variants and metabolism was analyzed also in two independent study groups: a total of 49 men from the population-based METSIM study (Metabolic Syndrome in Men) and 113 non-diabetic individuals from the EUGENE2 study (European Network on Functional Genomics of Type 2 Diabetes).

**Results:** Expression of the short mRNA variant, lacking exons 12, 13 and 13a, decreased after weight loss in subcutaneous fat ( $n=46$ ;  $p=0.0001$ ) and liver ( $n=11$ ;  $p=0.008$ ). Furthermore, the variant was more common in subcutaneous fat of subjects with type 2 diabetes than in subjects with normal glucose tolerance both in obese individuals ( $n=54$ ;  $p=0.002$ ) and in a population-based sample ( $n=49$ ;  $p=0.031$ ). Additionally, there was a positive correlation between this variant and the level of fasting glucose in non-diabetic individuals ( $n=113$ ;  $p=0.026$ ). This association between TCF7L2 splicing and plasma glucose was independent of the TCF7L2 genotype. Finally, this variant associated with high levels of serum FFAs during hyperinsulinemia ( $p=0.0009$ ) suggesting impaired insulin action in adipose tissue, whereas no association with insulin secretion or insulin-stimulated whole body glucose uptake was observed.

**Conclusion:** Our study shows that the short TCF7L2 mRNA variant in subcutaneous fat is regulated by a weight loss and is associated with hyperglycemia and impaired insulin action in adipose tissue.

### High insulin levels should be used for selection of patients with morbid obesity for bariatric surgery to achieve the best reduction of cardiovascular events

H.P. Kopp<sup>1</sup>, J.M. Brix<sup>1</sup>, G.H. Scherthaner<sup>2</sup>, G. Scherthaner<sup>1</sup>;

<sup>1</sup>Department of Medicine I, Rudolfstiftung Hospital, <sup>2</sup>Department of Medicine II, Medical University of Vienna, Austria.

**Background and aims:** Worldwide a huge number of patients undergo bariatric surgery, but the selection criteria for patients to achieve the best benefits from surgery are unclear. In the on-going debate for identification of possible indicators, preferably to be measured pre-surgery, we investigated the association of baseline Insulin levels with a detailed cardiovascular risk factor profile (CVRFP) up in one of the largest consecutive cohorts of patients with morbid obesity (MO) available.

**Materials and methods:** In total 1134 patients with MO (mean BMI:  $45.1 \pm 6.6$  kg/m<sup>2</sup>; mean age:  $39 \pm 12$  years; 79.4% females) were studied. Blood samples were taken from all patients to measure kidney, inflammatory parameters, fasting blood glucose, HbA1c and Insulin levels as well as lipids. Thus a CVRFP was established. Patients were divided according to their Baseline Insulin level into tertiles (0–18 µU/ml; 18,01–28.39 µU/ml; >28.4 µU/ml) into groups of 378 patients each. Differences were tested by using ANOVA as appropriate.

**Results:** Patients within the highest insulin tertile (see table) were significantly younger ( $p<0.001$ ), had a higher BMI ( $p<0.001$ ) and had the highest CVRFP: Higher levels for systolic and diastolic blood pressure, triglycerides and blood glucose levels as well as lower levels HDL cholesterol, and the lowest LDL-cholesterol ( $p<0.001$ ). 6.8% of patients in the lowest insulin tertile where suffering Type 2 Diabetes, whereas in the second insulin tertile 11.3% of patients and in the highest insulin tertile 21.5% of patients had Type 2 diabetes.

**Conclusion:** Our study indicates that MO patients with Insulin levels in the highest tertile at baseline have the worst cardiovascular risk factor profile and might thus be the best candidates for bariatric surgery. Thus the patients with the highest unmet need of cardiovascular mortality and events reduction would be selected for the procedure which has been become limited to high demands and costs, recently.

Table

	First Tertile	Second Tertile	Third Tertile	p-value
Systolic Blood Pressure, mmHg	139±17	143±17	145±16	$p<0.001$

<sup>1</sup>First Department of Propaedeutic Medicine, <sup>2</sup>Laboratory of Experimental Surgery and Surgical Research “NS Christeas”, <sup>3</sup>First Department of Surgery, Athens University Medical School, Greece.

**Background and aims:** Bariatric surgery is currently the most effective method for weight loss in morbid obesity, with variable, however, effects on glucose and lipid metabolism. The aim of this study was to compare the impact of two bariatric procedures on glucose, triglyceride and insulin serum levels, as well as insulin resistance and the subjective perception of hunger and satiety.

**Materials and methods:** Twenty three obese patients were recruited. Eleven underwent Roux-en-Y Gastric Bypass (RYGB, BMI:  $48.1 \pm 6.0$  kg/m<sup>2</sup>, age:  $38.1 \pm 8.0$  years) and 12 sleeve gastrectomy (SG, BMI:  $50.1 \pm 7.4$  kg/m<sup>2</sup>, age:  $39.8 \pm 7.5$  years,  $p$  vs RYGB=NS). Patients visited our department preoperatively as well as 3 and 6 months postoperatively. Blood samples were collected after an overnight fast and every 30 minutes after consumption of a 450 kcal (200 ml ice cream) test meal until 180 minutes postprandially. They also completed a visual analog scale questionnaire for the subjective rating of hunger and satiety every 30 minutes. Differences in glucose, triglycerides, insulin, hunger and satiety were examined in terms of area under the curve divided by time (AUC) using the trapezoid rule. Insulin resistance was estimated with the HOMA-IR index (Homeostatic Model Assessment-Insulin Resistance).

**Results:** Patients in both groups had no preoperative differences in any of the above variables and experienced significant ( $p<0.001$ ) and comparable weight loss both 3 and 6 months postoperatively (BMI for RYGB at 6 months:  $35.2 \pm 4.9$  vs SG:  $37.2 \pm 6.2$  kg/m<sup>2</sup>,  $p=NS$ ). A significant reduction in insulin resistance at 3 (RYGB:  $p=0.026$ , SG:  $p=0.027$ ) and 6 months (RYGB:  $p=0.01$ , SG:  $p=0.001$ ), glucose at 6 months (RYGB:  $p=0.007$ , SG:  $p=0.022$ ) and insulin at 3 and 6 months ( $p<0.01$ ) in both groups was observed. Moreover, the RYGB group displayed a significant reduction in triglyceride levels at 6 months ( $p=0.033$ ) and a reduction in the perception of hunger at 3 ( $p=0.016$ ) and 6 months ( $p=0.044$ ). Patients in either group did not experience significant differences in satiety perception. Comparing the two procedures, there was a significant difference in triglyceride concentrations 3 (AUC RYGB:  $107 \pm 26$  vs SG:  $139 \pm 26$  mg/dl,  $p=0.013$ ) and 6 months (AUC RYGB:  $86 \pm 26$  vs SG:  $135 \pm 33$  mg/dl,  $p=0.002$ ) after surgery.

**Conclusion:** Both RYGB and SG lead to significant and comparable weight loss, as well as decreases in glucose, insulin, and insulin resistance. Gastric bypass favors an improved postprandial triglyceride response and a blunted sense of hunger.

## 725

**Arterial stiffness decreases after bariatric surgery in patients with morbid obesity**R. Tirado<sup>1</sup>, G. Llauro<sup>1</sup>, M. Villaplana<sup>1</sup>, P. Rebas<sup>2</sup>, A. Luna<sup>2</sup>, B. Pons<sup>1</sup>, J.M. González-Clemente<sup>1</sup>, A. Caixàs<sup>1</sup><sup>1</sup>Endocrinology and Nutrition Department, <sup>2</sup>Surgery Department, Hospital de Sabadell. Corporació Sanitaria Parc Taulí. Sabadell. Institut Universitari Parc Taulí- UAB Universitat Autònoma de Barcelona, Sabadell, Spain.

**Background and aims:** Increased arterial stiffness is independently associated with high risk for cardiovascular morbidity and mortality. Morbidly obese subjects have increased arterial stiffness, compared with healthy subjects, that decreases after weight loss. The aim of this study is to measure the arterial stiffness in morbidly obese subjects, before and after bariatric surgery, and to study its relationship with anthropometric parameters, insulinresistance index and plasma lipids.

**Materials and methods:** Forty-four patients have been studied, 39 women and 5 men, (age  $43.05 \pm 7.96$  years, BMI  $44.9 \pm 4.45$  Kg/m<sup>2</sup>). Forty-eight percent had hypertension, 34% type 2 diabetes and 39% dislipidaemia. The arterial stiffness was assessed by applanation tonometry on the radial artery (Sphygmocor<sup>®</sup> versión 7.0 AtCor Medical, Sidney, Australia). The variables obtained were: the augmentation index adjusted for heart rate (IAx@75), central systolic pressure (CSP) and central pulse pressure. Also, BMI, waist circumference, % body fat by bioelectrical impedance, (TANITA), HOMA insulinresistance index (HOMA) and plasma lipid levels were measured. All measurements were done at baseline and one year after bariatric surgery. In a subgroup of patients (n=21), carotid-femoral pulse wave velocity (PWV) was also measured before and until 2 years after surgery. For the statistical analysis SPSS-PC-plus version 19 was used.

**Results:** At 12 months after surgery, all patients showed a decrease in BMI ( $44.9 \pm 4.46$  vs  $29.4 \pm 3.54$  Kg/m<sup>2</sup>), % body fat ( $49.9 \pm 4.11$  vs  $33.8 \pm 7.15$  %), waist circumference ( $131.3 \pm 12.9$  vs  $102.4 \pm 11.0$  cm) and HOMA ( $4.61 \pm 2.60$  vs  $1.3 \pm 0.83$ ), and an improvement of lipid parameters,  $p < 0.001$  in all of them. CSP and IAx@75 also decreased at 12 months ( $110.4 \pm 18.3$  vs  $124.8 \pm 15.9$  mmHg and  $21.13 \pm 12.6$  vs  $25.07 \pm 11.0$  %,  $p < 0.005$ , respectively). The reduction in IAx@75 and CSP, after bariatric surgery correlated only with the reduction in the percentage of body fat ( $b = 0.544$ ,  $p < 0.01$   $y = 0.357$ ,  $p = 0.028$ ). PWV also decreased at 2 years after surgery ( $7.52 \pm 1.56$  vs  $6.84 \pm 1.14$  m/s,  $p = 0.004$ ) but no correlations were found with any of the variables.

**Conclusion:** Morbidly obese patients show a decrease in arterial stiffness after bariatric surgery related to the decrease in body fat.

## 726

**Insulin secretion and sensitivity after bariatric surgery: laparoscopic gastric banding vs biliopancreatic diversion**J. Vrbikova<sup>1</sup>, T. Grimmichova<sup>1</sup>, K. Dvorakova<sup>1</sup>, J. Vcelak<sup>1</sup>, O. Bradnova<sup>1</sup>, T. Halkova<sup>1</sup>, M. Fried<sup>2</sup>, P. Sramkova<sup>2</sup>, K. Dolezalova<sup>2</sup>, R. Bilek<sup>1</sup>, M. Hill<sup>1</sup>, V. Hainer<sup>1</sup>, P. Mc Ternan<sup>3</sup>, I. Kyrou<sup>3</sup>, S. Kumar<sup>3</sup><sup>1</sup>Institute of Endocrinology, Prague, Czech Republic, <sup>2</sup>OB Klinika, Prague, Czech Republic, <sup>3</sup>University Hospital Coventry and Warwickshire, WISDEM, Warwick Medical School, University of Warwick, Coventry, UK.

**Background and aims:** Mechanisms by which bariatric surgery improves diabetes remain still elusive. We compare the effects of laparoscopic gastric banding (LAGB) and biliopancreatic diversion (BPD) on insulin sensitivity and insulin secretion.

**Materials and methods:** Women with type 2 diabetes mellitus (T2 DM) and obesity referred to bariatric surgery (LAGB, n=11; age  $54.4 \pm 9.5$  years, BMI  $44.7 \pm 6.8$  kg/m<sup>2</sup> T2DM lasting for  $4.5 \pm 4$  years; BPD, n = 12, age  $49.7 \pm 6$  years, BMI  $48 \pm 7.6$  kg/m<sup>2</sup>, T2DM lasting for  $5.7 \pm 6.7$  years) were examined by euglycaemic clamp and mixed meal test with modelling of insulin secretion before, and 1 and 6 months after the operation. Results are given as median (lower quartil; upper quartil). Statistics: ANOVA

**Results:** BMI improved more after BPD (from  $44.3(42.3; 55.4)$  to  $41(38.6; 52.4)$  and to  $35.9(34.5; 39.2)$  vs in LAGB  $44.2(36.1; 50.4)$  to  $42.1(33.48.1)$  and  $38.4(29.5; 42.6)$  kg/m<sup>2</sup>;  $p = 0.001$ ). HbA<sub>1c</sub> decreased significantly (in BPD from  $52.5(47.5; 58.8)$  to  $45.5(44.3; 48.5)$  and to  $39.5(38.4; 45.8)$ , in LAGB from  $51(47.5; 55)$  to  $45(44.0; 49.0)$  and to  $43.5(40.8; 46.3)$  mmol/mol;  $p = 0.001$ ) and fasting blood glucose improved (in BPD from  $7.85(7.1; 10.6)$  to  $5.85(5.6; 6.38)$  and to  $5.85(5.45; 7.1)$ ; in LAGB from  $8.1(7.9; 11.1)$  to  $6.4(5.9; 7.4)$  and to  $6.5(5.9; 7.25)$  mmol/l;  $p = 0.001$ ) after both types of operations. Insulin sensitivity

expressed as glucose disposal per kg of fat free mass (FFM) improved similarly after both LAGB and BPD (in BPD from  $20.2(13.6; 32.4)$  to  $30(21.6; 46.5)$  and to  $33.1(30.6; 35.8)$ ; in LAGB from  $16.4(14.8; 26.1)$  to  $27.3(26.2; 33.1)$  and to  $37.3(25.9; 40.6)$   $\mu$ mol/kg FFM;  $p = 0.02$ ), whereas insulin secretion early after meal (ISR 15min) at 1 month postoperatively decreased in BPD (from  $3.79(2.85; 3.87)$  to  $2.31(2.19; 2.96)$  pmol/kg min;  $p = 0.05$ ) but did not change after LAGB ( $4.21(3.8; 4.34)$  vs.  $3.8(3.4; 4.12)$  pmol/kg min). Glucose dependent insulinotropic peptide (GIP) levels decreased significantly after BPD but not after LAGB (30min from  $480(422; 595)$  to  $263(196; 310)$  and to  $260(244; 325)$  pg/ml;  $p = 0.001$ ; 60min from  $328(309; 658)$  to  $195(171; 258)$  and to  $268(220; 358)$  pg/ml;  $p = 0.001$ ; 120min from  $371(231; 537)$  to  $222(155; 271)$  and to  $265(155; 479)$  pg/ml;  $p = 0.001$ ; 180min from  $269(225; 367)$  to  $183(142; 238)$  and to  $225(155; 340)$  pg/ml;  $p = 0.01$ ). Glucagon-like peptide 1 increased after BPD but no significant change after LAGB was seen in 60min (from  $128(110; 165)$  to  $161(128; 194)$  and to  $175(167; 193)$  pg/ml;  $p = 0.05$ ). GLP-1 at 180min increased after BPD from  $131(123; 150)$  to  $189(146; 243)$  and to  $174(153; 208)$  pg/ml;  $p = 0.05$ ) but decreased (from  $167(112; 183)$  to  $156(112; 176)$  and to  $150(135; 296)$   $p = 0.05$ ) after LAGB. GIP30 after BPD correlates with ISR 15 but not with insulin sensitivity ( $r = 0.496$ ,  $p = 0.004$ ).

**Conclusion:** Both LAGB and BPD led to the improvement in insulin sensitivity. Insulin secretion did not change after LAGB. However, after BPD, early insulin secretion decreased and was correlated with decreased GIP levels.

**Decreased micro-particel associated tissue factor activity in morbid obese patients after bariatric surgery**L. Ay<sup>1</sup>, J.M. Brix<sup>1</sup>, J. Thaler<sup>2</sup>, G. Scherthaner<sup>3</sup>, C. Ay<sup>2</sup>, I. Pabinger<sup>2</sup>, G. Scherthaner<sup>1</sup><sup>1</sup>Department of Medicine I, Rudolfstiftung Hospital, Vienna, <sup>2</sup>Division of Haematology and Haemostaseology, Department of Medicine I, Medical University of Vienna, <sup>3</sup>Department of Medicine II, Medical University of Vienna, Austria.

**Background and aims:** Tissue factor (TF) plays a crucial role in the initiation of blood coagulation. Active circulating TF was detected on small negatively charged membrane vesicles, so called MPs, which are released upon cell activation and apoptosis from variety of cells. Increased number and/or procoagulant activity of microparticles (MPs) have been reported in morbid obese patients and may mediate the thrombotic propensity. Our objective was to determine the effect of bariatric surgery on the MP-associated tissue factor (TF) activity in morbid obese patients.

**Materials and methods:** MP-TF activity was measured with a TF-dependent factor Xa generation assay. We investigated MP-TF activity in morbid obese patients (n= 74) that were included in our study. Seventy-four MO patients (mean age:  $42 (\pm 11)$  years; 61 female) were investigated before and 2 years after bariatric surgery. Within this period the body mass index decreased from (mean  $\pm$  SD)  $45 \pm 10$  to  $30 \pm 7$  ( $p < 0.001$ ).

**Results:** A significant improvement of metabolic parameters was observed after weight loss (Table 1) and of c-reactive protein from preoperatively  $1.1 \pm 1.1$  mg/dL to  $0.4 \pm 0.6$  mg/dL. Postoperatively the median (25th-75th percentile) MP-TF activity decreased significantly from  $0.120(0.180-0.480)$  pg/mL to  $0.022(0.000-0.279)$  pg/mL ( $p = 0.002$ ). There was a statistically significant correlation between the preoperatively MP-TF activity and c-reactive protein ( $r = 0.3$ ;  $p = 0.02$ ).

**Conclusion:** In conclusion, we could demonstrate for the first time a significant decrease of the MP-TF activity using a chromogenic assay after weight loss in morbid obese patients.

Table 1

	Pre-Surgery	Post-Surgery	p-value
HbA1c, %	$6.0 \pm 1.0$	$5.4 \pm 0.5$	$p < 0.001$
total cholesterol, mg/dl	$204 \pm 34$	$179 \pm 35$	$p < 0.001$
HDL cholesterol, mg/dl	$50 \pm 12$	$58 \pm 19$	$p < 0.001$
LDL cholesterol, mg/dl	$122 \pm 32$	$101 \pm 31$	$p < 0.001$
Triglycerides, mg/dl	$130 \pm 21$	$90 \pm 20$	$p < 0.001$

## 728

### Inhibition of gut peptide responses to food ingestion modulates the brain's response to food ingestion after Roux-en-Y gastric bypass: a FDG-PET neuroimaging study

K.F. Hunt<sup>1</sup>, J.T. Dunn<sup>2</sup>, P.K. Marsden<sup>2</sup>, L.J. Reed<sup>3</sup>, A.G. Patel<sup>4</sup>, S.A. Amiel<sup>1</sup>;

<sup>1</sup>Diabetes Research Group, Diabetes and Nutritional Sciences Division, King's College London School of Medicine, <sup>2</sup>Division of Imaging Sciences, King's College London School of Medicine, <sup>3</sup>Neuropsychopharmacology Unit, Imperial College London, <sup>4</sup>King's College Hospital, London, UK.

**Background and aims:** Roux-en-Y gastric bypass (RYGB) causes sustained weight loss but the mechanisms are not fully understood. Modulation of central control of appetite by exaggerated gut peptide responses to eating may contribute. Inhibition of gut peptide responses, using somatostatin, decreases fullness and increases food intake after RYGB.

**Aim:** To investigate the effect of inhibiting gut peptide responses to food ingestion on the brain responses to eating in people who have lost weight post RYGB, using [18F]-fluorodeoxyglucose positron emission tomography (FDG-PET) functional neuroimaging.

**Materials and methods:** Seven people 19±13 months post RYGB (weight loss 31.3±9.6%; BMI 34.2±4.2 kg/m<sup>2</sup>; HOMA2-IR 0.68±0.22) underwent 4 FDG-PET scanning visits after overnight fasting in random order in a 2x2 factorial design: with intravenous (IV) somatostatin (0.1 mcg/kg/min) and IV basal insulin replacement (3.6 mU/m<sup>2</sup>/min) or with IV saline (placebo); and consuming 400 kcal meal before scanning (FED) or remaining fasted (FASTED). Satiety was assessed on 0–100 visual analogue scales (VAS); blood was sampled; regional brain FDG uptake, a surrogate for neuronal activation, was measured from 15 to 70 minutes post meal. Two non-operated groups, one obese (n=8; BMI 34.2±2.7 kg/m<sup>2</sup>; HOMA2-IR 0.56±0.2) and one normal weight (n=11; BMI 22.2±1.5 kg/m<sup>2</sup>; HOMA2-IR 0.53±0.16) have been studied in a similar protocol.

**Results:** With placebo, the FED (compared to FASTED) state post-RYGB was associated with decreased (voxelwise  $p<0.001$ , cluster size threshold 100 voxels) FDG uptake in regions involved in interoception (insular); reward (ventral striatum & globus pallidus); cognitive control (dorsolateral frontal cortex, DLFC, & anterior cingulate cortex, ACC); and resting state network (precuneus & parietal lobule), whereas in non-operated subjects FED (vs FASTED) was associated with increased FDG uptake in regions involved in reward (ventral striatum & globus pallidus) and, in the normal weight group only, a small decrease in FDG uptake in regions involved in cognitive control (DLFC & ACC). Post RYGB somatostatin, vs placebo, inhibited post-meal increases in insulin (+0.5±1.3 vs +35.5±25.5 mU/l), glucagon-like peptide-1 (+0.1±0.5 vs +16.1±10.7 pM) and peptide YY (-1.0±0.6 vs +79.7±25.7 pg/ml) and decreased fullness at 10 minutes (49.8 vs 74.8,  $p=0.049$ ). Post RYGB somatostatin, vs placebo, also attenuated the effect of food ingestion in insular, ventral striatum, globus pallidus, DLFC, ACC, precuneus and parietal lobule ( $p<0.05$ ) towards the patterns seen in the non-operated groups.

**Conclusion:** Increased fullness on eating after RYGB is associated with reversal of the brain's response to food ingestion in regions involved in reward, and replication of the normal deactivation in regions involved in cognitive control. These changes in the central responses to food ingestion, which may associate with negative rather than positive experiences of eating and improved executive control, may contribute to the weight loss seen after RYGB. The response to somatostatin is consistent with altered gut peptide response to eating mediating a major part of this effect.

### Exenatide plus metformin compared to metformin alone on beta cell function in type 2 diabetic patients

P. Maffioli<sup>1</sup>, I.G. Franzetti<sup>2</sup>, F. Querci<sup>3</sup>, A. Carbone<sup>4</sup>, L. Ciccirelli<sup>5</sup>, M. Piccinni<sup>6</sup>, E. Fogari<sup>1</sup>, M.A. Ferraro<sup>7</sup>, G. Derosa<sup>1</sup>;

<sup>1</sup>Internal Medicine and Therapeutics, University of Pavia, IRCCS Policlinico S.Matteo, Pavia, <sup>2</sup>Metabolic Unit, Regional Hospital, Varese, <sup>3</sup>Diabetes Care Unit, Ospedale Pesenti Fenaroli, Bergamo, <sup>4</sup>Internal Medicine, Hospital Center of Diabetes, Lodi, <sup>5</sup>Internal Medicine, RSA Villa Mafalda, Pavia, <sup>6</sup>Internal Medicine, Fondazione Ospedale della Carità, Cremona, <sup>7</sup>Diabetologia, PST Gallico, Reggio Calabria, Italy.

**Background and aims:** In previously reported studies, exenatide proved to be effective in reducing insulin resistance and increasing  $\beta$ -cell function, giving also a decrease of body weight and inflammatory state. The aim of this study was to quantify how much exenatide added to metformin improves  $\beta$ -cell function, and to evaluate the impact on glycemic control, insulin resistance, and inflammation compared to metformin alone.

**Materials and methods:** 174 Caucasian type 2 diabetic patients, naïve and with poor glycaemic control, were instructed to take metformin for 8±2 months until a mean dosage of 2500±500 mg/day, then they were randomly assigned to take exenatide (5 µg twice a day for the first 4 weeks, 10 µg twice a day thereafter) or placebo volume equivalent for 12 months. We evaluated at 3, 6, 9, and 12 months: body mass index (BMI), glycemic control, fasting plasma insulin (FPI), homeostasis model assessment insulin resistance index (HOMA-IR), homeostasis model assessment  $\beta$ -cell function index (HOMA- $\beta$ ), fasting plasma proinsulin (FPPr), proinsulin/fasting plasma insulin ratio (Pr/FPI ratio), C-peptide, glucagon, adiponectin (ADN), high sensitivity-C reactive protein (Hs-CRP), and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ). Before, and after 12 months since the addition of exenatide, patients underwent a combined euglycaemic hyperinsulinemic and hyperglycaemic clamp, with subsequent arginine stimulation, to assess insulin sensitivity and insulin secretion. Continuous variables were evaluated using analysis of variance (ANOVA) tests. Intervention effects were adjusted for the presence of potential confounding variables using analysis of covariance (ANCOVA). ANOVA was also used to assess variables' significance within and between groups.

**Results:** Exenatide+metformin gave a greater decrease of body weight and BMI ( $p<0.01$  for both), glycaemic control ( $p<0.05$ ), FPI ( $p<0.05$ ), FPPr ( $p<0.05$ ), FPPr/FPI ratio ( $p<0.05$ ), HOMA-IR ( $p<0.05$ ), and glucagon ( $p<0.05$ ) values and a greater increase of C-peptide levels ( $p<0.05$ ), HOMA- $\beta$  ( $p<0.05$ ) and ADN ( $p<0.05$ ) compared to placebo+metformin. Exenatide+metformin, but not placebo+metformin, also decreased TNF- $\alpha$  and Hs-CRP ( $p<0.05$  compared to baseline for both, not significant vs placebo+metformin). Exenatide+metformin treatment gave a greater increase of M value (+34%), and Disposition Index (+55%) compared to placebo+metformin; 1<sup>st</sup> (+21%) and 2<sup>nd</sup> phase (+34%) C-peptide response to glucose and C-peptide response to arginine (+25%) were also improved by exenatide+metformin treatment, but not by placebo+metformin.

**Conclusion:** Exenatide confirmed its efficacy on glycaemic control, and its positive effective in protecting  $\beta$ -cell and in reducing inflammation.

## 730

### GLP-1 agonists and insulin in obese insulin-treated patients with type 2 diabetes: combined treatment or substitution? Weight and metabolic benefits

F. Bertoin, A. Paoli, D. Ancelle, B. Decoudier, M. Francois, C. Lukas-Croisier, E. Bertin, M. Crouzet, P. Moysset, A.-C. Hécart, D. Malgrange, B. Delemer; Reims University Hospital, France.

**Background:** GLP-1 agonists have pleiotropic effects. They particularly increase satiety and decrease glucagon secretion which might be interesting in insulin-treated type 2 diabetic patients even more when they are obese.

**Aims:** To assess and to compare the weight and metabolic benefits obtained with two different therapeutic strategies: Insulin in combination with GLP-1 agonist or switch insulin to GLP-1 agonist (to respect the product license in France).

**Materials and methods:** French monocentric retrospective study from 2008 to 2010 with a cohort of 148 insulin-treated type 2 diabetic patients.

**Results:** 101 patients had association (group 1); 47 patients had switch (group 2). Baseline characteristics were similar in both groups except insulin daily dose which was significantly lower in group 2 (0.97 vs 0.66 units/day). Mean age: 59.3 vs 57.8 years old; mean BMI: 38.9 vs 39.3 kg/m<sup>2</sup>; diabetes duration: 19.2 vs 16.3 years; insulin was begun after a ten-year evolution; mean HbA1c: 8.6%. The addition of GLP-1 agonists to insulin enables a decrease of HbA1c about -0.84 % at 6 months and about -0.34% after one year, a weight loss of 5 Kg, a 9% reduction of the basal insulin dose and a withdrawal of rapid insulin in 30% of cases. Substitution leads to a better weight benefit ( $p=0.007$ ) but without any glycemic interest which becomes worse in 45% (21/47) of the patients. No result after a 6 month- treatment predicts the absence of response afterwards and should lead to GLP-1 agonist discontinuation.

**Conclusion:** Adding GLP-1- analogs and maintain insulin seems to be the safest strategy. This association results in a satisfying weight loss with a slight improvement of HbA1c and a reduction of the global daily insulin dose.

## 731

### Add-on treatment of GLP-1 based therapy in patients with type 2 diabetes treated with insulin: an observational study

W.T. Zandee<sup>1</sup>, M.A. Sleddering<sup>2</sup>, I. Jazet<sup>2</sup>, A.H. Bootsma<sup>1</sup>, P.H.L. Geelhoed-Duijvestijn<sup>1</sup>

<sup>1</sup>Internal Medicine, Medical Center Haaglanden, The Hague, <sup>2</sup>Internal Medicine, Leiden University Medical Center, Netherlands.

**Background and aims:** In the Netherlands GLP-1 based therapy is reimbursed to treat type 2 diabetes (DM2) not in control with a combination of metformin and SU-derivatives and a BMI>35. However, patients already on insulin might also benefit from this therapy by losing weight and lowering insulin dose. A 5% or more decrease in weight is known to have significant metabolic effects. Thus far, only few results have been published on the combination with insulin in daily practice. Aim of this study is to evaluate the results of GLP-based therapy in addition to insulin, treated “off-label” in our outpatient diabetes clinic.

**Methods:** Data were collected from all patients in our Medical Center using insulin, who were started on either liraglutide or exenatide. HbA1c, weight and insulin dose were collected at baseline, at six months and one year after the start and/or at last follow-up. Values were compared using a mixed model for repeated measurements. Categorical variables were analyzed with the McNemar’s test for paired proportions. A backward conditional linear regression analysis was performed to identify independent determinants of the decrease in HbA1c, body weight and total daily dose (TDD) of insulin at 6 months follow-up.

**Results:** 150 patients were included. Mean age was 56 years and the mean follow-up was 10.4 months. 33 patients stopped within 3 months of therapy most of them due to side effects or an increase in glucose values. Baseline HbA1c was 9.32% and 8.82% and 8.86% at 6 and 12 months resp. ( $P<0.05$ ). The average weight decreased from 105.3kg to 99.2kg after 12 months ( $P<0.01$ ). At 6 months 59% of patients lost more than 5% of their body weight. Average insulin dose decreased from 73.8IU to 18.7 IU after 12 months ( $P<0.01$ ). Insulin was discontinued in 56% of patients. At baseline 5.0% of patients reached a HbA1c <7.0% and after 6 months this number increased to 16.5% ( $P<0.01$ ). HbA1c decrease at 6 months was predicted by insulin dose at baseline (negative) and the decrease in weight (positive) ( $R=0.40$ ,  $R^2=0.16$ ,  $F=9.77$ ). Decrease in weight was predicted by decrease in TDD of insulin (positive) and HbA1c at baseline (negative), ( $R=0.52$ ,  $R^2=0.27$ ,  $F=19.37$ ,  $P<0.001$ ). Decrease of insulin dose was predicted by HbA1c at baseline (negative), the decrease in weight after 6 months (positive) and the addition of an SU-derivate (positive), ( $R=0.50$ ,  $R^2=0.26$ ,  $F=12.64$ ,  $P<0.001$ ).

**Conclusion:** Our results show that GLP-1 based therapy can successfully be used to treat obese DM2 not in control on insulin and results, if tolerated, in a 10% increase of patients reaching treatment goals.

## 732

### Safety and efficacy of liraglutide in type 2 diabetes: post marketing surveillance data from India

S.K. Wangnoo<sup>1</sup>, A. Mithal<sup>1</sup>, S. Kumar<sup>2</sup>, K.D. Modi<sup>3</sup>, P. Shamanna<sup>4</sup>, R. Shetty<sup>5</sup>; <sup>1</sup>Dept. of Endocrinology, Indraprastha Apollo Hospital, New Delhi, <sup>2</sup>Dept. of Endocrinology & Metabolism, Sir Ganga Ram Hospital, New Delhi, <sup>3</sup>Dept. of Endocrinology, Shanti Niketan, Hyderabad, <sup>4</sup>Bangalore Diabetes Centre, Kalyan Nagar, Bangalore, <sup>5</sup>Novo Nordisk India Pvt. Ltd, Bangalore, India.

**Background and aim:** Liraglutide is recently approved and available in India. Here we present an interim analysis of a post marketing surveillance (PMS) (LEAD-IN) study of liraglutide in Indian subjects with type 2 diabetes mellitus (T2DM). The objective of this study was to assess the safety and efficacy of liraglutide in real-life situations in India.

**Material and methods:** LEAD-IN is an ongoing multicenter, open-label, PMS study for 52 weeks. Subjects with T2DM  $\geq 18$  years; with or without prior treatment with anti-diabetic drugs and considered clinically suitable for liraglutide therapy were enrolled. Subjects are planned to be evaluated at baseline, after 13 and 26 weeks of therapy for safety and efficacy. Additionally it is planned to evaluate subjects for the next 26 weeks (total 52 weeks) for safety. During the study clinically required concomitant medications were allowed. Here we present data of an interim analysis of 13 weeks.

**Results:** Total 1416 subjects (M: 809; F: 607) were enrolled in the study and 1322 completed 13 weeks follow up. The mean age was 46.8 years and mean duration of diabetes was 7.18 years. Total 16 subjects reported adverse events (excluding hypoglycaemia) the most common adverse events were nausea (N=7), vomiting (N=9) and back pain (N=1). At baseline, 104 (7.3%) and 5 (0.4%) subjects reported minor and major hypoglycaemia preceding 4 weeks which was reduced to 64 (4.8%) to 0(0%) after 13 weeks of liraglutide therapy. No serious adverse event was noted. Furthermore significant improvement in serum creatinine and lipid profile was noticed. Table 1 shows reduction in glycaemic and non-glycaemic parameters. At 13 weeks, change in HbA1c, FPG and PPG was  $-1.03 \pm 0.86$  ( $-5.8;3.1$ );  $-29.7 \pm 33.43$  ( $-231;126$ ) and  $-58.1 \pm 52.40$  ( $-270; 135$ ) respectively.

**Conclusion:** This interim analysis of the open label, observational LEAD-IN study demonstrates the favourable safety of liraglutide in Indian subjects of T2DM in real-life situation. Additionally significant improvement in glycaemic control was noticed.

**Table 1: Reduction in Glycaemic and Non-glycaemic Parameters**

Parameter	Baseline (Mean $\pm$ SD)	After therapy (Mean $\pm$ SD)	p value
HbA1C (%)	8.77 $\pm$ 1.26	7.76 $\pm$ 0.93	<0.0001
FPG (mg/dL)	170.00 $\pm$ 47.97	140.10 $\pm$ 35.05	<0.0001
PPG* (mg/dL)	246.80 $\pm$ 61.23	190.30 $\pm$ 46.11	<0.0001
Body weight (kg)	92.54 $\pm$ 14.62	88.71 $\pm$ 13.57	<0.0001
BMI (kg/m <sup>2</sup> )	34.38 $\pm$ 5.49	32.97 $\pm$ 5.21	<0.0001
SBP (mm of Hg)	134.40 $\pm$ 15.26	126.50 $\pm$ 9.44	<0.0001
DBP (mm of Hg)	85.50 $\pm$ 8.79	82.30 $\pm$ 5.51	<0.0001
Serum Creatinine (mg/dL)	1.02 $\pm$ 0.70	0.90 $\pm$ 0.42	<0.0001
Urine Albumin (mg/dL)	12.11 $\pm$ 15.69	10.85 $\pm$ 13.35	0.166
Total Cholesterol (mg/dL)	187.30 $\pm$ 42.64	172.78 $\pm$ 32.99	<0.0001
HDL (mg/dL)	43.62 $\pm$ 12.07	47.21 $\pm$ 16.31	<0.0001
LDL (mg/dL)	109.16 $\pm$ 36.75	102.34 $\pm$ 29.40	<0.0001
Triglyceride (mg/dL)	152.02 $\pm$ 66.87	130.79 $\pm$ 52.72	<0.0001

\* post breakfast; paired t-test was applied,  $p < 0.005$ : statistically significant.

## 733

**One-year effects of liraglutide on pancreatic beta cell function and glycaemic control in Japanese type 1 diabetes with residual insulin secretion**

Y. Hamamoto, K. Mori, S. Honjo, Y. Kawasaki, K. Fujimoto, H. Tatsuoka, A. Matsuoka, Y. Wada, H. Ikeda, H. Koshiyama;  
Center for Diabetes and Endocrinology, Kitano Hospital, Osaka, Japan.

**Background and aims:** Since GLP-1 receptor agonists have been reported to be protective against  $\beta$ -cell destruction, they are expected to be beneficial for glycemic control in patients with type 1 diabetes (T1D) with residual  $\beta$ -cell function. The aim of this study was to investigate the effect of liraglutide, a long-acting GLP-1 receptor agonist, on pancreatic  $\beta$ -cell function and glycaemic control in Japanese patients with T1D with residual insulin secretion.

**Materials and methods:** In this open-labeled, randomized, parallel-group study, a total of ten subjects with type T1D (age  $48.5 \pm 12.1$  yrs, BMI  $22.8 \pm 1.8$ ; mean  $\pm$  SD) who were positive for GADAb or IA-2Ab and had been treated with insulin more than one year with residual insulin secretion which was defined by C-peptide (CPR) more than 0.3 ng/ml were included. Group A was administered liraglutide 0.9 mg in addition to ongoing insulin therapy for 52 weeks, and insulin group B continued the ongoing insulin injection. Changes in HbA1c, blood glucose (BG) with self-monitoring of blood glucose (SMBG), postprandial plasma CPR levels, body weight, dose of insulin injection per day, and adverse events (AE) were investigated. Pancreatic  $\beta$ -cell function was evaluated by glucagon- and arginine-stimulation test which was performed before and 52 weeks after, and CPR index which were calculated by the following formula [CPR/Blood Glucose (BG)].

**Results:** In group A, HbA1c value tended to decrease from  $7.6 \pm 1.4\%$  to  $7.3 \pm 1.5\%$  at 52 weeks with decreased daily insulin dose from  $40.8 \pm 20.6$  to  $33.8 \pm 17.4$  units although it did not reach statistical significance ( $p=0.39$ ). On the other hand, in group B, HbA1c remained unchanged from  $7.7 \pm 0.7$  to  $7.8 \pm 0.9\%$  with slightly increased insulin dose from  $37.7 \pm 12.2$  to  $40.2 \pm 14.2$  units. It is notable that insulin dose was reduced in 80% of group A whereas none in group B could reduce it. Averaged incremental CPR value in arginine-stimulated test and CPR secretion in response to glucagon-stimulation showed a slight decrease in both groups but there was no statistical significance between the groups. However, in subjects with obvious improvement of glycemic control, liraglutide increased casual CPR levels and CPR response to arginine-stimulation suggesting that the responses to liraglutide was varied in the individual cases. The CPR index calculated with postprandial CPR and BG tended to increase in group A but not in group B. No AE including severe hypoglycemia was observed in both groups.

**Conclusion:** These data suggest that addition of liraglutide on ongoing insulin therapy has a potential to improve and stabilize BG with reduction of daily insulin dose. The major effect of liraglutide was likely to be exhibited through extra- $\beta$ -cell effects such as suppression of glucagon secretion rather than an increase of insulin secretion. However, a beneficial effect on  $\beta$ -cell function was suggested, indicating that longer period observation might detect the beneficial effect. Further investigation with increased number of subjects and longer period of observation will be needed, and currently the study is still ongoing.

## 734

**Microalbuminuria is an independent risk factor for nausea caused by glucagon-like peptide-1 receptor agonists**

H. Umematsu, R. Suzuki, M. Awazawa, Y. Hada, Y. Izumida, N. Shojima, Y. Okazaki, M. Fujishiro, Y. Iizuka, H. Sakoda, M. Ohsugi, K. Hara, T. Yamauchi, K. Ueki, T. Kadowaki;  
Department of Diabetes and Metabolic Diseases, Graduate School of Medicine, The University of Tokyo, Japan.

**Background and aims:** Nausea is one of the most common adverse reactions caused by treatment with glucagon-like peptide-1 receptor agonists (GLP-1 RAs) for type 2 diabetes. Although this symptom often leads to withdrawal of the treatment, it is yet to be clarified whether we can predict high-risk patients in advance. The objective of this study was to investigate the association of clinical parameters and incidence of nausea among patients with type 2 diabetes during treatment with GLP-1 RAs.

**Materials and methods:** We conducted a case-control study using the medical records of adult type 2 diabetes patients who started treatment with GLP-1 RAs between September 2010 and January 2012 during hospitalization at our

hospital. The number of patients who experienced nausea was retrospectively counted. Microvascular complications and clinical parameters were evaluated in nausea group and non-nausea group. Microalbuminuria was defined as a spot urine albumin-to creatinine-ratio (ACR) between 30 and 300 mg/g. Severity of diabetic retinopathy was evaluated by ophthalmologists. Diabetic neuropathy was diagnosed based on impairment of vibration sense or diminished deep tendon reflexes. Two-group comparisons were made using  $\chi^2$  tests and student t tests. To assess significant predictors of nausea, we performed multivariate analysis in a stepwise multiple logistic-regression model.

**Results:** GLP-1 RAs (0.3 mg once-daily liraglutide or 5  $\mu$ g twice-daily exenatide, as standard initial dose in Japan) were administered to 66 adult patients (36 males and 30 females; age  $59 \pm 12$  yrs; duration of type 2 diabetes  $11.7 \pm 7.8$  yrs; HbA1c  $9.0 \pm 1.6\%$ ; BMI  $30.5 \pm 6.9$  kg/m<sup>2</sup>). At baseline, the patients were treated with diet therapy alone (1%), oral hypoglycemic agents (38%), or insulin (61%). All cases were reviewed and none were excluded. Nausea was observed in 26 patients (39%). The discontinuation rate was 9%. Between the nausea and non-nausea groups, urine ACR (215 mg/g vs 84.3 mg/g), HbA1c (8.4% vs 9.3%), and estimated GFR (67.8 ml/min/1.73 m<sup>2</sup> vs 84.0 ml/min/1.73 m<sup>2</sup>) were significantly different ( $P=0.0085$ ,  $P=0.014$ ,  $P=0.017$ , respectively). Gender, age, BMI, duration of type 2 diabetes, waist circumferences, and the brands of GLP-1 RAs were not different statistically. According to multivariate logistic regression analysis, presence of microalbuminuria was significantly associated with nausea ( $P=0.0058$ ), even after adjustment for the brands of GLP-1 RAs, HbA1c, estimated GFR, diabetic retinopathy, diabetic neuropathy, and hypertension. In albuminuria (microalbuminuria or proteinuria) group ( $n=36$ ), the incidence rate of nausea was significantly increased (OR 2.50 [95% CI 1.10–5.73]  $P=0.048$ ). However, between microalbuminuria group ( $n=22$ ) and proteinuria group ( $n=14$ ), no significant difference was observed (OR 1.29 [95% CI 0.73–2.28]). Data are given as mean  $\pm$  SD.

**Conclusion:** Microalbuminuria is linked with an increased risk of nausea due to GLP-1 RAs. Gastrointestinal symptoms should be carefully monitored when GLP-1 RAs are administered to patients with albuminuria.

## 735

**A possible way to improve the glycaemic control and the beta cell function during three years: the triple therapy**

G. Derosa<sup>1</sup>, P.D. Ragonesi<sup>2</sup>, A.F.G. Cicero<sup>3</sup>, I.G. Franzetti<sup>4</sup>, F. Querci<sup>5</sup>, A. Carbone<sup>6</sup>, M.N. Piccinni<sup>7</sup>, A. D'Angelo<sup>1</sup>, E. Fogari<sup>1</sup>, P. Maffioli<sup>1</sup>;  
<sup>1</sup>Internal Medicine and Therapeutics, University of Pavia, IRCCS Policlinico S. Matteo, Pavia, <sup>2</sup>Diabetes Care Unit, S. Carlo Hospital, Milan, <sup>3</sup>"G. Descovich" Atherosclerosis Study Center, University of Bologna, <sup>4</sup>Metabolic Unit, Regional Hospital, Varese, <sup>5</sup>Diabetes Care Unit, Ospedale Pesenti Fenaroli, Bergamo, <sup>6</sup>Diabetes Care, Hospital Center of Diabetes, Lodi, <sup>7</sup>Internal Medicine, Fondazione Ospedale della Carità, Cremona, Italy.

**Background and aims:** When metformin monotherapy is not enough to reach an adequate glycaemic control, combination therapy is required. The aim of this study was to evaluate the effects of a triple therapy of metformin + pioglitazone + sitagliptin or metformin + pioglitazone + glibenclamide compared to metformin monotherapy or a double combination of metformin + pioglitazone on glycaemic control, insulin resistance, and  $\beta$ -cell function in type 2 diabetic patients.

**Materials and methods:** During the two years run-in period, 476 patients were instructed to take metformin and pioglitazone until a mean dosage of 1850  $\pm$  15 mg/day. At the end of the run-in period, 445 patients were randomised to add glibenclamide 5 mg three times a day or sitagliptin 100 mg once a day to metformin 2200 mg/day + pioglitazone 30 mg/day for one year in a double blind design. We evaluated at the baseline, and after 6, 12, 18, 24, 30 and 36 months: glycated hemoglobin (HbA<sub>1c</sub>), fasting plasma insulin (FPI), HOMA-IR, HOMA- $\beta$ , fasting plasma proinsulin (FPPR), C-peptide. At the baseline and every six months, patients underwent a combined euglycaemic hyperinsulinemic and hyperglycaemic clamp. Continuous variables were evaluated using analysis of variance (ANOVA) tests. Intervention effects were adjusted for the presence of potential confounding variables using analysis of covariance (ANCOVA). For all statistical analyses,  $p < 0.05$  was considered statistically significant.

**Results:** Both the triple therapies were more effective in reducing HbA<sub>1c</sub> compared to metformin monotherapy ( $p < 0.001$ ), and dual therapy metformin + pioglitazone ( $p < 0.02$ ). FPI, and HOMA-IR were significantly increased by triple therapy with glibenclamide ( $p < 0.05$  vs metformin, and  $p < 0.05$  vs metformin + pioglitazone), and decreased by the one with sitagliptin ( $p < 0.05$  vs glibenclamide). While sitagliptin did not change HOMA- $\beta$ , it was significantly increased by glibenclamide ( $p < 0.0001$  vs metformin, and  $p < 0.0001$  vs

pioglitazone). FPPr was not influenced by triple therapy with glibenclamide, while it was decreased by the one with sitagliptin ( $p<0.01$  vs metformin, and  $p<0.05$  vs glibenclamide). Both glibenclamide and sitagliptin triple therapies increased C-peptide compared to baseline ( $p<0.05$  for glibenclamide, and  $p<0.02$  for sitagliptin). Regarding clamp derived measures of  $\beta$ -cell function, triple therapy with sitagliptin better improved all the measures compared to the glibenclamide one ( $p<0.05$  for all), and also compared with metformin monotherapy ( $p<0.01$ ), and metformin + pioglitazone ( $p<0.05$ ).

**Conclusion:** Dual combination therapy is more effective than monotherapy in improving glycaemic control; furthermore, when metformin and pioglitazone combination is not enough, sitagliptin should be preferred to glibenclamide as addition to the already ongoing therapy, for its better protection of  $\beta$ -cell secretion, and its neutral effect on body weight.

## 736

### The gut hormone GLP-1 improves the postprandial (PP) glycaemia in type 2 diabetes mellitus by insulin, glucagon, and gastric emptying

B. Aulinger, A. Bedorf, G. Kutscherauer, B. Göke, J. Schirra;

Department of Internal Medicine II, Campus Großhadern, University of Munich, Germany.

**Background and aims:** Gut born GLP-1 decreases PP glycemia in healthy subjects by stimulation of insulin and reduction of glucagon. GLP-1 inhibits gastric motility. The insulinotropic action contributes to the incretin effect, i.e. the difference between the PP and the isoglycemic fasting insulin response. A defect of this enteroinsular axis has been suggested in T2DM, the function of GLP-1 is, however, unknown. We examined the antidiabetic effects of GLP-1 in T2DM using the GLP-1R antagonist exendin(9-39) (Ex-9) with and without stimulation of the endogenous GLP-1 by the DPP-4 inhibitor Sitagliptin.

**Materials and methods:** Double-blind, placebo-controlled, four-arm-cross-over study in 24 patients with T2DM ( $61\pm7$  y, HbA1c  $6.2\pm0.2$ , BMI  $27.7\pm0.9$ ). On four days separated by a wash-out period of at least one week blood glucose, plasma insulin and glucagon concentrations, and gastric emptying (13C acetate breath test) were measured during the four hours after ingestion of an OGTT (75g). In a randomized fashion, oral treatment with placebo or 100 mg Sitagliptin was combined with an intravenous infusion of saline or Ex-9 at 900 pmol/kg/min. The dose of Ex-9 used here blocks the insulinotropic effect of GLP-1 in human by at least 95%. On four further days blood glucose excursions obtained during the OGTTs were mimicked by intravenous glucose (isoglycemic clamp) for calculation of the incretin effect.

**Results:** see table. Compared to saline iv Ex-9 increased PP blood glucose ( $P=0.004$ ), decreased both plasma insulin ( $P<0.001$ ) and the incretin effect ( $P=0.012$ ), and increased plasma glucagon ( $P=0.005$ ) excursions with and without Sitagliptin. Sitagliptin increased PP plasma GLP-1 ( $P<0.001$  vs placebo po) and lowered PP blood glucose ( $P<0.001$  vs placebo po) not only without but also with Ex-9. In spite of the lower PP glycemia, Sitagliptin increased PP plasma insulin ( $P<0.001$ ), and this again was not dependent on background infusion. Sitagliptin enhanced the incretin effect compared to placebo ( $P=0.043$ ) which was reduced but eliminated under Ex-9. During the first 120min Sitagliptin lowered PP plasma glucagon with saline iv ( $P=0.045$ ), but not with Ex-9 iv ( $P=0.221$ ). Ex-9 accelerated and Sitagliptin delayed gastric emptying, but Sitagliptin had no effect on gastric emptying during Ex-9.

**Conclusion:** Endogenous GLP-1 lowers PP glycemia after an OGTT in T2DM by stimulation of insulin, inhibition of glucagon and delay of gastric emptying. Acute DPP-4 inhibition by Sitagliptin improves glucose tolerance by enhancing endogenous GLP-1 action. However, Sitagliptin decreases PP glycemia by stimulation of insulin even independent of GLP-1.

Blood glucose, plasma hormones and gastric emptying after an OGTT in T2DM

	Placebo po + saline iv	Sitagliptin po + saline iv	Placebo po + Ex-9 iv	Sitagliptin po + Ex-9 iv

### Comparison of GLP-1R expression in C-cells isolated from rat and human thyroid glands

G. Dietert<sup>1</sup>, M. Dorau<sup>1</sup>, M. Heinrichs<sup>1</sup>, A. Perren<sup>2</sup>, A. Blank<sup>2</sup>, T. Kissner<sup>1</sup>;

<sup>1</sup>Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany,

<sup>2</sup>University of Bern, Switzerland.

**Background and aims:** In rodent thyroid glands, some glucagon-like peptide-1 receptor (GLP-1R) agonists have been shown to induce C-cell proliferation. Rodents appear to be particularly sensitive, and it remains to be determined whether this is a drug class effect. To evaluate if GLP-1R expression on C-cells is rodent-specific, we investigated GLP-1R expression levels in C-cells isolated from untreated human and rat thyroids.

**Materials and methods:** Rat and human C-cells were excised by laser capture microdissection from paraffin-embedded thyroid glands, and total RNA was isolated. Quantitative real-time polymerase chain reaction was performed to analyse GLP-1R gene expression levels; GLP-1R expression levels were normalized to  $\beta$ -actin levels.

**Results:** GLP-1R expression in rat C-cell fractions ( $n=15$ ) was reflected in a cycle time (CT) mean value of  $27.4 \pm 1.5$  and a value of 4 when normalized to  $\beta$ -actin (Table). In a study with human C-cell fraction ( $n=2$ ), only marginal GLP-1R expression levels were observed, reflected by a CT mean value of  $33.6 \pm 0.6$ , close to the sensitivity limit of the test system ( $CT=35$ ) and 10.4 when normalized to  $\beta$ -actin. In a second study with human tissue ( $n=7$ ), no relevant GLP-1R expression was demonstrated in C-cell fractions.

**Conclusion:** GLP-1R expression analysis in human and rat thyroid glands revealed higher GLP-1R expression in rat C-cells compared with human C-cells, with a CT difference of at least six CTs, corresponding to a 64-fold higher RNA content in rats. The higher GLP-1R expression in rats may underlie the particular sensitivity of rodents for GLP-1R agonist-induced proliferation of thyroid C-cells.

Expression of the GLP-1R in rat and human thyroid C-cell fractions

Target	Expression level, mean CT value* $\pm$ SD (range)		
	Study 1: Rat C-cells (n=15-18)	Study 2: Human C-cells (n=2)	Study 1: Human C-cells (n=7)
$\beta$ -actin <sup>†</sup>	23.5 $\pm$ 1.1 (21.7-24.9)	23.2 $\pm$ 0.4 (23.0-23.5)	24.6 $\pm$ 3.8 (19.3-30.6)
Calcitonin <sup>‡</sup>	18.1 $\pm$ 1.3 (16.4-21.8)	20.7 $\pm$ 1.0 (20.0-21.4)	26.6 $\pm$ 2.8 (22.8-30.4)
GLP-1R	27.4 $\pm$ 1.5 (24.1-29.5)	33.6 $\pm$ 0.6 (33.2-34.0)	Undetectable (all values >35, except one [34.9])

## 738

### Is introduction of GLP-1 agonist and hypocaloric diet justified and safe for obese type 2 diabetes patients treated with insulin?

M. Vrtovec;

Department of Endocrinology, University Medical Centre, Ljubljana, Slovenia.

**Background and aims:** Patients with type 2 diabetes and BMI over 35 kg/m<sup>2</sup> are at much higher risk than non obese patients. We sought to investigate whether the introduction of GLP-1 agonist together with hypocaloric diet (5 MJ) was safe for insulin treated patients with type 2 diabetes and BMI over 35 kg/m<sup>2</sup> and whether it resulted in lower HbA<sub>1c</sub> and greater weight reduction.

**Materials and methods:** 20 patients (9 women, 11 men) with type 2 diabetes and body mass index (BMI) over 35 kg/m<sup>2</sup> (42.8  $\pm$  7.3), treated with metformin and insulin, were observed. They were 41-78 (60.2  $\pm$  8.3) years old, with diabetes duration of 6-37 (16.4  $\pm$  8.8) years, treated with metformin and insulin for 1-11 years (4.7  $\pm$  2.6 years). At baseline 5 MJ diet was suggested, exenatide 5 mcg BID was introduced, short acting or 50% premixed insulins were switched to NPH or long acting analogs in reduced daily insulin dose (TDI) by 50%, 25%/30% mixtures of biphasic insulins twice daily were only reduced. The patients had to do a 7 point daily glucose profile before each visit and also between the 3rd and 7th day after the introduction of exenatide, in other days only FPG. After 1 month, exenatide dose was increased to 10 mcg BID. TDI was further reduced by 50% and the patients were instructed to adjust daily insulin dose at FBG levels below 8 mmol/l and over 10 mmol/L.

**Results:** After 6 months of treatment, we observed a significant decrease in HbA<sub>1c</sub> (from 9.4  $\pm$  1.3 % to 8.1  $\pm$  1.3 %,  $p < 0.05$ ), and an average 13 kg body weight reduction (123.5  $\pm$  22.4 kg to 110.7  $\pm$  18.0 kg,  $p < 0.05$ ). The average FPG was 10.3 mmol/L and the average of blood glucose profile 10.6 mmol/L. Insulin was withdrawn in 16 patients (80%), but to 9 of them sulphonylureas were prescribed later. Only 7 patients (35%) reported mild adverse events during the introduction of exenatide, and only one patient reported about 5 hypoglycemia in the first month, when he tried to reach FPG below 6 mmol/L.

**Conclusion:** Introduction of GLP-1 agonist together with hypocaloric diet in obese patients with diabetes type 2 is justified and safe. The expected benefits are better glycemic regulation, greater weight loss, much lower insulin dose and in some cases also withdrawal of insulin. Hypoglycaemia can occur in patients treated with insulin together with exenatide and hypocaloric diet if the target value of FBG is set to low.

#### Ipragliflozin reduced HbA<sub>1c</sub> and body weight in Japanese type 2 diabetes patients who have inadequate glycaemic control on sulfonylurea or pioglitazone alone

A. Kashiwagi<sup>1</sup>, T. Shiga<sup>2</sup>, N. Akiyama<sup>2</sup>, K. Kazuta<sup>2</sup>, H. Ogasawara<sup>2</sup>, S. Yoshida<sup>2</sup>, E. Ueyama<sup>2</sup>, A. Utsuno<sup>2</sup>;

<sup>1</sup>Shiga University of Medical Science, <sup>2</sup>Astellas Pharma Inc., Tokyo, Japan.

**Background and aims:** Ipragliflozin (IPRA, ASP1941), a sodium glucose cotransporter 2 (SGLT2) inhibitor, successfully completed a phase 3 clinical monotherapy trial (EASD 2011; 149-OP) for the treatment of type 2 diabetes mellitus (T2DM) in Japanese patients. Here we report the results of 2 studies to assess the efficacy, safety, and tolerability of IPRA added to a sulfonylurea (SU) or pioglitazone (PIO) in Japanese T2DM patients who have inadequate glycaemic control while on a SU or PIO alone.

**Materials and methods:** In 2 independent, randomized, placebo-controlled, double-blind parallel group studies, patients entered a 4-week screening period followed by a 2-week single blind run-in period, and were randomized to either IPRA or placebo at a 2:1 ratio. Patients received 50 mg IPRA or placebo once daily in combination with either a SU (N = 242) or PIO (N = 151) at the constant approved dose of either any of the SUs or PIO in Japan.

**Results:** At week 24, IPRA significantly reduced HbA<sub>1c</sub> compared with placebo with a change of -1.14% in the SU and -0.88% in the PIO study, respectively ( $P < 0.001$ ; Table). In addition, more patients on IPRA reached target HbA<sub>1c</sub> of <7.0% (19.4% and 12.4%) compared with placebo (5.3% and 0.0%) in the SU and PIO studies respectively. Fasting plasma glucose (FPG) levels compared with placebo were also significantly decreased for both studies ( $P < 0.001$ ; Table). A significant decrease in body weight compared with placebo was observed in the IPRA group with a change of -1.32 kg for the SU study and -2.79 kg for the PIO study ( $P < 0.001$ ; Table). Also observed were decreases in systolic and diastolic blood pressure in the IPRA group compared with the placebo group. The incidences of hypoglycaemia, genital infections, and urinary tract infections with IPRA occurred in 1.2%, 0.6%, and 1.2% of patients in the SU study, respectively, and 1.0%, 2.1%, and 3.1% in the PIO study, respectively; the incidences in the placebo arm were respectively 1.3%, 3.9%, and 3.9% in the SU study and 0.0%, 0.0%, and 1.9% in the PIO study, respectively.

**Conclusion:** Ipragliflozin as a 50 mg once daily oral dose added to a SU or PIO during a 24-week period was efficacious and well tolerated in Japanese T2DM patients. Additional benefits of body weight and blood pressure reductions were also observed.

Table: Baseline and adjusted mean change from baseline at 24 weeks

		Sulfonylurea (N = 240)		Pioglitazone (N = 151)

\*The value for HbA<sub>1c</sub> (%) is estimated as an NGSP value (%) calculated by the formula: HbA<sub>1c</sub> (%) = 1.02 × HbA<sub>1c</sub> (JDS [%]) + 0.25%, considering the relational expression of HbA<sub>1c</sub> (JDS [%]) measured by the previous Japanese standard substance and measurement methods and HbA<sub>1c</sub> (NGSP).

NGSP, the National Glycohemoglobin Standardization Program; JDS, the Japan Diabetes Society

<sup>†</sup>Based on an analysis of covariance model that includes baseline HbA<sub>1c</sub>, FPG, or body weight as a covariate and treatment group as a fixed effect.

<sup>‡</sup>P < 0.001.

CI, confidence interval; FPG, fasting plasma glucose; SD, standard deviation.

Clinical Trial Registration Number: NCT01242215 and NCT01225081

## 740

### Luseogliflozin (TS-071), a selective SGLT2 inhibitor, improves glycaemic control and lowers body weight in a 12-week study in Japanese patients with type 2 diabetes mellitus

Y. Seino<sup>1</sup>, T. Sasaki<sup>2</sup>, A. Fukatsu<sup>3</sup>, Y. Samukawa<sup>4</sup>, S. Sakai<sup>4</sup>, T. Watanabe<sup>4</sup>;

<sup>1</sup>Kansai Electric Power Hospital, Osaka, <sup>2</sup>Jikei University School of Medicine, Tokyo, <sup>3</sup>Yachiyo Hospital, Aichi, <sup>4</sup>Taisho Pharmaceutical Co., Ltd., Tokyo, Japan.

**Background and aims:** Renal sodium-glucose co-transporter (SGLT) 2 inhibition is a new approach to the treatment of type 2 diabetes mellitus (T2DM). Luseogliflozin (LUSEO) is orally bioavailable and is a highly selective SGLT2 inhibitor with an IC<sub>50</sub> value of 2.26 nmol/L, and exhibits >1000-fold selectivity over SGLT1. In a previous exploratory 12 weeks study, once daily administration of LUSEO demonstrated clinical amelioration in HbA<sub>1c</sub> and other glycaemic parameters, and showed a favourable safety profile. The present study was designed to investigate the efficacy and safety of LUSEO monotherapy in Japanese patients with T2DM.

**Materials and methods:** In this double-blind, placebo (PBO)-controlled, parallel group, dose-finding study, 280 patients were randomised to LUSEO 1, 2.5, 5, or 10 mg once daily or PBO for 12 weeks. Patients aged 20–74 years with HbA<sub>1c</sub> 6.9–10.4 %, who had received regular diet therapy but no antidiabetic drugs for the twelve weeks before randomisation, were recruited to this study. The primary endpoint was change in HbA<sub>1c</sub> from baseline at end of treatment. The secondary endpoints were changes in fasting plasma glucose (FPG), postprandial plasma glucose (PPG) and body weight from baseline at end of treatment. Safety and tolerability were also evaluated.

**Results:** Baseline demographics and disease characteristics were similar among all groups. Mean baseline characteristics in each group were HbA<sub>1c</sub> 7.77–8.05%, FPG 149.3–158.9 mg/dL, PPG at 2-hours after meal test 245.2–257.7 mg/dL, and body weight 61.0–72.6 kg. After 12 weeks administration of LUSEO 1 mg–10 mg, HbA<sub>1c</sub>, FPG, 2-hour PPG and body weight were decreased significantly versus PBO (Table 1). There was a significant decrease in systolic blood pressure reductions without a relevant change in pulse rate in all LUSEO groups. The frequency of adverse events was similar in all groups. No major or serious safety concern was observed in any of the LU-

SEO groups. No hypoglycaemia (less than 70 mg/dL blood glucose level) was observed. Although 18 pollakisuria or urine output increases were observed in all LUSEO groups, all of these events were mild in severity.

Table 1. LS mean change from baseline at the end of trial.

	PBO (n=56)	LUSEO 1 mg (n=55)	LUSEO 2.5 mg (n=55)	LUSEO 5 mg (n=54)	LUSEO 10 mg (n=58)
HbA <sub>1c</sub> (%)	0.23	−0.29	−0.42	−0.46	−0.43
difference from PBO	−	−0.52 *	−0.65 *	−0.69 *	−0.66 *
FPG (mg/dL)	8.9	−10.6	−18.6	−21.1	−21.1
difference from PBO	−	−19.6 *	−27.6 *	−30.1 *	−30.1 *
2-hour PPG (mg/dL)	5.1	−44.7	−54.9	−55.5	−43.6
difference from PBO	−	−49.8 *	−60.0 *	−60.5 *	−48.6 *
Body weight (kg)	0.15	−0.81	−1.39	−1.97	−1.90
difference from PBO	−	−0.96 *	−1.54 *	−2.12 *	−2.05 *

ANCOVA with baseline as covariate for HbA<sub>1c</sub>, FPG and 2-hour PPG, ANOVA for Body weight. \*: P<0.001 vs. PBO

**Conclusion:** LUSEO ameliorated the glycaemic parameters and induced bodyweight reduction. Glycaemic control by LUSEO at 2.5 mg or higher doses was similar, and LUSEO showed a favourable safety profile, as was found in the previous exploratory study.

## 741

### Luseogliflozin (TS-071), a selective SGLT2 inhibitor, improves glycaemic control in Japanese type 2 diabetic subjects with renal impairment

M. Haneda<sup>1</sup>, Y. Seino<sup>2</sup>, A. Fukatsu<sup>3</sup>, T. Sasaki<sup>4</sup>, Y. Samukawa<sup>5</sup>, S. Sakai<sup>5</sup>, Y. Sato<sup>5</sup>, T. Watanabe<sup>5</sup>;

<sup>1</sup>Asahikawa Medical University, Hokkaido, Japan, <sup>2</sup>Kansai Electric Power Hospital, Osaka, Japan, <sup>3</sup>Yachiyo Hospital, Aichi, <sup>4</sup>Jikei University School of Medicine, Tokyo, <sup>5</sup>Taisho Pharmaceutical Co., Ltd., Tokyo, Japan.

**Background and aims:** SGLT2 inhibition is known as a new approach for the treatment of type 2 diabetes mellitus (T2DM). Luseogliflozin (LUSEO) is a highly selective inhibitor of SGLT2. This study was conducted to evaluate the effect of LUSEO on urinary glucose excretion (UGE) and plasma glucose levels, the pharmacokinetics, and safety in Japanese T2DM subjects with renal impairment and normal renal function.

**Materials and methods:** Japanese T2DM subjects with normal renal function (NRF [eGFR (mL/min/1.73m<sup>2</sup>)] 90–), and mild (G2 [eGFR 60–89]), moderate (G3 [eGFR 30–59]), and severe (G4 [eGFR 15–29]) renal impairment received a single oral dose of LUSEO (5 mg) before breakfast (n = 57). Pharmacodynamic parameters were measured to compare the values before and after administration of LUSEO, and pharmacokinetic parameters were compared between the administration groups. The per cent inhibition of glucose reabsorption by the kidney in all groups was analysed.

**Results:** Mean 24-hour urinary glucose excretion was significantly increased from baseline levels in all groups (ΔUGE (g, mean ± SD): NRF, 88.3 ± 36.9; G2, 69.7 ± 19.1; G3, 45.3 ± 16.8; G4, 21.8 ± 7.1). The values of postprandial plasma glucose (PPG: 2 hours after breakfast) were significantly decreased from baseline levels in all groups, except G4 (ΔPPG (mg/dL): NRF, −49.3 ± 33.6; G2, −33.6 ± 27.1; G3, −24.4 ± 34.7; G4, −3.3 ± 32.1). Moreover, the values of fasting plasma glucose (FPG) 24 hours after administration of LUSEO were also significantly decreased from baseline levels in all groups, except G4 (ΔFPG (mg/dL): NRF, −28.7 ± 22.0; G2, −16.2 ± 18.3; G3, −7.7 ± 13.4; G4: 10.3 ± 12.1). The average inhibition of glucose reabsorption by the kidney after LUSEO administration was almost 36% in all groups. LUSEO-induced increases in UGE were dependent on filtered glucose load, which is directly proportional to eGFR. Systemic exposure (AUC<sub>inf</sub> of plasma LUSEO concentration) was comparable among all groups. No serious adverse event or renal/urinary tract adverse event was observed during the study period.

**Conclusion:** LUSEO may be effective and may not require dose adjustment in the treatment of T2DM subjects even with mild to moderate renal impairment. A long-term clinical trial to assess the efficacy of LUSEO in T2DM subjects with moderate renal impairment is in progress.

## 742

# Luseogliflozin (TS-071), a novel, potent, and selective inhibitor of SGLT2 is safe and well-tolerated in type 2 diabetes mellitus and showed dose-dependent PK/PD in both US/Japanese ethnicities

L.A. Morrow<sup>1</sup>, M.J. Gutierrez<sup>2</sup>, Y. Tanaka<sup>3</sup>, H.D. Sabia<sup>3</sup>, K. Shimasaki<sup>3</sup>, H. Ochiai<sup>4</sup>, S. Yasuda<sup>4</sup>, Y. Samukawa<sup>4</sup>, M. Hompesch<sup>1</sup>, D.P. Rossignol<sup>2</sup>;

<sup>1</sup>Profil Institute for Clinical Research, Chula Vista, USA, <sup>2</sup>Comprehensive Clinical Development, Miramar, USA, <sup>3</sup>Taisho Pharmaceutical R&D USA, Morristown, USA, <sup>4</sup>Taisho Pharmaceutical CO., LTD., Tokyo, Japan.

**Background and aims:** Luseogliflozin (LUSEO) has previously been shown to enhance urine glucose excretion (UGE) and lower plasma glucose in studies with Japanese (JP) subjects with type 2 diabetes mellitus (T2DM). Currently we demonstrate that LUSEO is safe, tolerable, and active in US subjects with T2DM.

**Materials and methods:** This double blind, randomized, multiple ascending dose, placebo (PBO) controlled study assessed the pharmacokinetics (PK), pharmacodynamics (PD), safety and tolerability of LUSEO after q.d. oral dosing for 7 days in 72 subjects with T2DM in the US (HbA1c: 8.2±0.85%, age: 55±8.3, body weight (BW): 84±17 kg, gender: 50% female, ethnicity: 87.5% white). Study cohorts received 1, 2.5, 5, 10, 15 or 25 mg LUSEO or PBO prior to breakfast, 10:2 in each cohort.

**Results:** PK parameters (C<sub>max</sub> and AUC) of LUSEO were dose proportional and reached steady state by Day 3. All doses stimulated UGE throughout the dosing period, and was strongly dose-dependent to 2.5 mg/day (Figure 1). Modeling of UGE predicted a 50% effective dose <1 mg, and E<sub>max</sub> (101 g/day) corresponded to 10 mg LUSEO (109 ± 36.4 g/day). Comparing Day 7 to baseline, 10 mg LUSEO decreased plasma glucose exposure by 25% (P=0.0004 vs PBO) and mean plasma glucose (MPG) by 60 mg/dL (28%: P=0.0003 vs PBO). There were no serious treatment-emergent adverse events (TEAE); no AE leading to discontinuation; no dose dependent TEAE, including the most common TEAE (GI: 21%: 1 moderate) and no clinically-defined hypoglycemia. Urinary AEs were rare (1 incidence each of pollakiuria and polyuria, no urinary tract infections). LUSEO dosing was associated with enhanced weight loss (1.3 -2 vs 0.8 kg in PBO). In comparison to a prior study with JP subjects, C<sub>max</sub> and AUC were decreased in US subjects. Further analysis indicated that these differences may be related to differences in BW which were different in the two study populations (JP BW: 71±12 kg). In both US and JP populations, mean UGE was roughly similar up to doses of 5 mg. While effects on plasma glucose were affected by baseline disease severity in these small short-duration studies, preliminary findings of reductions in MPG and fasting plasma glucose appear to be optimal at 2.5 mg/day in JP subjects, but may require higher doses in US subjects.

**Conclusion:** Repeated dosing of LUSEO for 7 days demonstrated dose proportional PK at doses up to 25 mg, predictable PD, and was safe and well-tolerated in subjects with T2DM in the US. As a function of dose, exposure was lower in US subjects than in JP subjects, suggesting that treatment of US patients is likely to require higher doses of LUSEO than JP patients. Ultimately, establishing optimal dosing will require the use of more robust biomarkers of glucose exposure such as HbA1c.

## 743

# Safety of dapagliflozin in clinical trials for type 2 diabetes mellitus

K. Johnson<sup>1</sup>, A. Ptaszynska<sup>2</sup>, A. Apanovitch<sup>3</sup>, J.E. Sugg<sup>4</sup>, S.J. Parikh<sup>4</sup>, J.F. List<sup>2</sup>;

<sup>1</sup>AstraZeneca, Mölndal, Sweden, <sup>2</sup>Bristol-Myers Squibb, Princeton, USA,

<sup>3</sup>Bristol-Myers Squibb, Pennington, USA, <sup>4</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin (DAPA), a sodium glucose cotransporter 2 (SGLT2) inhibitor, reduces hyperglycaemia in an insulin-independent manner by increasing renal glucose excretion, and represents a potential option for T2DM patients. The aim of this analysis was to assess safety across the DAPA clinical development programme.

**Materials and methods:** Data were pooled from 12 phase 2b/3 short-term double-blind placebo (PBO)-controlled trials (4684 patients) to examine overall safety. An updated database of 19 trials (8685 patients; 1.8:1 cumulative exposure ratio for DAPA:control) was used to examine rare events.

**Results:** Adverse events (AEs) were slightly more common with DAPA vs PBO; serious AEs and discontinuations due to AEs were balanced across groups (Table 1). Hypoglycaemia was more common with DAPA vs PBO, driven by studies in which DAPA was combined with sulphonylurea or insulin. AEs of genital infections and UTI were more common with DAPA vs PBO with imbalances less marked for UTIs. These were mild/moderate, responded to standard antimicrobial therapy and rarely led to discontinuation. Mean changes from baseline in systolic/diastolic BP were -4.0/-2.0 vs -0.9/-0.5 mmHg for DAPA vs PBO without increases in measured orthostatic hypotension (3.9% vs 3.7% for DAPA vs PBO). AEs of volume depletion (hypotension/dehydration/hypovolaemia) were seen in 0.6-1.2% for DAPA 0.4% for PBO. AEs of renal impairment/failure were balanced across groups (0.9-1.4% for DAPA vs 0.9% for PBO). Minor changes in serum electrolytes were seen with DAPA, with small increases in serum Mg and P. PBO-corrected reductions in uric acid, in the studies it was analysed, ranged from -0.45 to -0.8 mg/dL (but reductions of less magnitude were noted in an add-on to insulin and a phase 2b monotherapy study). Incidence rates/100 pt years of malignant and unspecified tumours were similar for DAPA (1.39) vs control (1.34). Incidence rates of bladder cancer were 0.15 for DAPA vs 0.03 for control with an incidence rate (IR) difference of 0.117 (95%CI: -0.171, 0.367) and of breast cancer were 0.37 vs 0.22 respectively with an IR difference of 0.228 (95%CI: -0.537%, 0.806). Haematuria was noted at or before baseline in 7/10 patients with bladder cancer. All breast cancer events were reported within the first year of study initiation. Non-clinical DAPA data did not indicate any carcinogenic potential, and SGLT2 is selectively expressed in the kidney with no expression in human breast or bladder tissue. Elevated liver laboratory tests were seen in 4.4% vs 4.2% for DAPA vs control. Hazard ratio for CV death, MI, stroke or hospitalization for unstable angina for DAPA vs control was 0.82 (95% CI: 0.583, 1.152). Trends in CV events and specific malignancies will be further evaluated in a randomised CV outcomes trial and complementary observational studies.

**Conclusion:** Based on this large phase 2b/3 experience with >4500 T2DM patients, DAPA has an acceptable safety profile.

Table 1. Safety summary, short-term double-blind PBO-controlled pool

## 744

**Dapagliflozin improves glycaemic control and reduces body weight across various patient populations with type 2 diabetes mellitus**

S. Parikh<sup>1</sup>, E. Hardy<sup>1</sup>, L. Wei<sup>2</sup>, C. Wessman<sup>3</sup>, A. Salsali<sup>4</sup>, A. Ptaszynska<sup>4</sup>,  
<sup>1</sup>AstraZeneca, Wilmington, USA, <sup>2</sup>Bristol-Myers Squibb, Pennington, USA,  
<sup>3</sup>AstraZeneca, Mölndal, Sweden, <sup>4</sup>Bristol-Myers Squibb, Princeton, USA.

**Background and aims:** Dapagliflozin (DAPA), a selective sodium-glucose cotransporter 2 (SGLT2) inhibitor, reduces plasma glucose independently of insulin by increasing renal glucose excretion. The efficacy of DAPA in patients with T2DM across 5 clinical trials was assessed.

**Materials and methods:** Patients with T2DM received DAPA (2.5, 5, or 10 mg/d) or placebo for 24 wk as monotherapy (N=274, main cohort) or add-on to metformin (MET, N=546), glimepiride (GLIM, N=596), pioglitazone (PIO, N=420) or insulin (INS, N=807). The primary endpoint for all trials was mean change from baseline in HbA1c at week 24. Secondary endpoints included change from baseline in fasting plasma glucose (FPG), postprandial glucose (PPG, tested in add-on to GLIM and add-on to PIO studies), and body weight. The primary endpoint was analyzed by ANCOVA, excluding data after rescue (last observation carried forward). Secondary endpoints were analyzed by hierarchical testing.

**Results:** Mean baseline HbA1c ranged from 7.9% to 8.5%. Placebo-corrected adjusted mean changes from baseline in HbA1c for DAPA 10 mg/d ranged from -0.5% to -0.7% ( $P<0.001$  in all studies) (Figure). DAPA also reduced FPG in all studies, and PPG in the 2 trials where it was tested. Body weight was reduced by 1.5 to 2 kg with DAPA 10 mg/d compared with placebo in the add-on to MET, add-on to GLIM, add-on to PIO, and add-on to insulin trials ( $P<0.0001$  in all 4 studies). Placebo-corrected weight reductions of up to 1 kg were observed in the monotherapy trial, however these changes did not reach statistical significance due to a greater-than-expected weight effect in the placebo group. Dapagliflozin was generally safe and well tolerated in these trials. Signs and symptoms suggestive of urinary tract infection and genital infection were more commonly reported as adverse events in the dapagliflozin dose groups compared with placebo.

**Conclusion:** DAPA produced significant improvements in glycaemic control and body weight in various patient populations with T2DM across the treatment continuum, consistent with its insulin-independent mechanism of action.

**Figure.** Change from baseline in HbA1c in Phase 3 studies of dapagliflozin

## 745

**Efficacy and safety of dapagliflozin treatment for type 2 diabetes mellitus patients with comorbid cardiovascular disease and hypertension**

W. Cefalu<sup>1</sup>, L. Leiter<sup>2</sup>, T. DeBruin<sup>3</sup>, I. Gause-Nilsson<sup>4</sup>, J. Sugg<sup>3</sup>, S. Parikh<sup>3</sup>,  
<sup>1</sup>University of Louisiana, Baton Rouge, USA, <sup>2</sup>University of Toronto, Canada,  
<sup>3</sup>AstraZeneca, Wilmington, USA, <sup>4</sup>AstraZeneca, Mölndal, Sweden.

**Background and aims:** Dapagliflozin (DAPA), a selective SGLT2 inhibitor, is a glucuretic agent that reduces hyperglycaemia independent of insulin (INS) secretion or action. The mechanism of action and clinical profile of DAPA suggest that it may benefit patients with advanced type 2 diabetes mellitus (T2DM) and cardiovascular (CV) comorbidities. This study was 1 of 2 assess-

ing DAPA in this population. Enrolled patients had HbA1c  $\geq 7.0\%$ – $\leq 10.0\%$ , documented CV disease (CVD), and a history of hypertension (HTN).

**Materials and methods:** Randomised patients (N=922), aged  $\geq 45/50$  y (M/F), received double-blind DAPA 10 mg/d or placebo (PBO) for 24 wks added to usual care for T2DM and HTN (the 80-wk extension is ongoing). Patients receiving INS had their baseline (BL) INS dose reduced by 25%. Rescue medication was provided as required for glycaemic or HTN control. Patients were stratified by age, INS use, and time from the most recent qualifying CV event. Co-primary end points were change in HbA1c and patients (%) achieving a composite end point consisting of a reduction of HbA1c  $\geq 0.5\%$ , body weight (BW)  $\geq 3\%$ , and systolic blood pressure (SBP)  $\geq 3$  mm Hg.

**Results:** The mean age was 63 y; 42% were  $\geq 65$  y. Mean T2DM duration was 12 y. At BL, 41% of patients received 2 oral anti-hyperglycaemic agents. INS was used by 52% of patients, of which 17% used INS as the only treatment. The most common qualifying CV event was coronary heart disease (75%). Almost 13% of the patients had chronic heart failure. The duration of HTN was  $\geq 3$  y in 88% of the patients and  $\geq 10$  y in 50% of the patients. Greater reductions from BL occurred with DAPA vs PBO in HbA1c (BL 8.1%) and BW (BL 93.1 kg) and more patients in the DAPA group met the 3-item composite end point (Table). SBP (BL 133.2 mmHg) was reduced for DAPA vs PBO at 8 and 24 wks. The mean daily INS dose change for DAPA was 1.0 IU/d vs PBO 5.1 IU/d, nominal  $P<0.05$ . Age-stratified results ( $<65$  or  $\geq 65$  y) were similar to overall results, except SBP reduction, which did not differ significantly between DAPA and PBO groups for patients aged  $\geq 65$  y. The proportion of patients with serious adverse events (AEs, DAPA 5.9% vs PBO 5.6%), unadjudicated CV events reported as AEs (DAPA 5.2% vs PBO 4.8%) or serious AEs (DAPA 1.1% vs PBO 1.5%), and hypoglycaemia (DAPA 19.3% vs PBO 18.2%) were balanced between groups. More patients in the DAPA (17.2%) vs the PBO group (13.2%) had measured orthostatic HTN. Events of genital infections were more often seen in women than men, and more often reported for DAPA vs PBO. Events of urinary tract infections were similar for both groups.

**Conclusion:** DAPA, when added to standard of care in a 24-wk study of older T2DM patients with mean age  $>60$  y and comorbid CVD and HTN, while improving glycaemic and BP control, and reducing BW, did not adversely impact CV safety or frequency of hypoglycaemic events. These data indicate that DAPA is appropriate for use in patients with advanced T2DM and CVD.

**Efficacy of dapagliflozin compared with other oral antidiabetic agents added to metformin monotherapy among subjects with type 2 diabetes**

S.M. Goring<sup>1</sup>, T. Huang<sup>1</sup>, G. Wygant<sup>2</sup>, M. Grishchenko<sup>3</sup>, R. Townsend<sup>4</sup>,  
 A. Salsali<sup>2</sup>, I. Wood<sup>2</sup>, N. Hawkins<sup>6</sup>,  
<sup>1</sup>Oxford Outcomes, Vancouver, Canada, <sup>2</sup>Bristol-Myers Squibb, Princeton, USA, <sup>3</sup>Bristol-Myers Squibb, Rueil-Malmaison, France, <sup>4</sup>AstraZeneca, Zaventem, Belgium, <sup>5</sup>Bristol-Myers Squibb, Uxbridge, UK, <sup>6</sup>Oxford Outcomes, UK.

**Background and aims:** Dapagliflozin is a novel sodium-glucose co-transporter 2 (SGLT2) inhibitor that has demonstrated utility as add-on therapy to metformin among patients with type 2 diabetes mellitus (T2DM). Its efficacy and safety have been compared in randomized clinical trials (RCTs) vs glipizide (a sulfonylurea [SU]) and placebo; however, head-to-head data vs other antidiabetic agents are not available. We used indirect evidence from a network of RCTs to estimate the efficacy of dapagliflozin relative to other antidiabetic agents after one year of exposure. Outcomes considered were mean change from baseline HbA1c and weight, at 52 weeks. As a measure of safety,

we estimated the relative odds of experiencing hypoglycemia during the first year of treatment.

**Materials and methods:** We conducted a systematic literature review and network meta-analysis (NMA) of RCTs involving antidiabetic agents added to metformin. We searched EMBASE, MEDLINE, and the Cochrane Central Register of Controlled Trials from database inception to May 2011 as well as abstracts from selected 2010 conferences, clinical trial registries, reference lists of included studies and unpublished study reports. We included RCTs that enrolled subjects with T2DM inadequately controlled on metformin monotherapy. RCTs involving intensive diet regimens were included in a sensitivity analysis. The analysis was performed using fixed- and random-effects Bayesian NMA models. Mean change from baseline HbA1c and weight after 52 weeks of treatment were analyzed on the mean difference scale. The proportion of subjects with at least one episode of hypoglycemia was analyzed on the odds ratio scale.

**Results:** We identified 4270 abstracts, and six RCTs met inclusion criteria. Four RCTs compared dipeptidyl peptidase-4 (DPP-4) inhibitors with SUs, one compared a thiazolidinedione (TZD) with a SU, and one compared dapagliflozin with a SU. Two RCTs were identified which compared glucagon-like peptide-1 (GLP-1) analogues with SUs, but neither was eligible for the primary analysis. After one year of treatment, the mean change from baseline in HbA1c was -0.69% in the SU arms. Anchored on this estimate, the estimated mean change was -0.69% (95% CrI: -0.85 to 0.53) for dapagliflozin, -0.67% (95% CrI: -0.84 to -0.51) for TZDs and -0.61% (95% CrI: -0.70 to -0.53) for DPP-4 inhibitors. Based on an average weight gain of 1.31 kg observed in the SU trial arms, the absolute weight loss estimate was -3.36 kg (95% CrI: -5.72 to -1.04) for dapagliflozin and -0.61 kg (95% CrI: -1.81 to 0.51) for DPP-4 inhibitors. The RCT involving TZDs did not report weight change. Odds ratios for hypoglycemia associated with dapagliflozin compared with TZDs and DPP-4 inhibitors were similar: 0.92 (95% CrI: 0.09 to 3.88) and 0.81 (95% CrI: 0.18 to 2.59), respectively. However, the odds for hypoglycemia associated with dapagliflozin were statistically lower than with SUs (OR: 0.06; 95% CrI: 0.02 to 0.17).

**Conclusion:** Compared with existing licensed antidiabetic therapies, dapagliflozin offers similar HbA1c control with either similar or reduced risk of hypoglycemia and the additional benefit of sustained weight loss over one year. Supported by: BMS

## 747

### Dapagliflozin reduces renal threshold for glucose excretion in type 2 diabetes

R.A. DeFronzo<sup>1</sup>, M. Hompesch<sup>2</sup>, S. Kasichayanula<sup>3</sup>, X. Liu<sup>3</sup>, Y. Hong<sup>3</sup>, M. Pfister<sup>3</sup>, L.A. Morrow<sup>2</sup>, B.R. Leslie<sup>3</sup>, D.W. Boulton<sup>4</sup>, A. Ching<sup>3</sup>, F.P. LaCreta<sup>3</sup>, S.C. Griffen<sup>3</sup>

<sup>1</sup>University of Texas Health Science Center, San Antonio, <sup>2</sup>Profil Institute for Clinical Research, Chula Vista, <sup>3</sup>Bristol-Myers Squibb, Princeton, <sup>4</sup>Bristol-Myer Squibb, Princeton, USA.

**Background and aims:** Dapagliflozin is a selective sodium-glucose co-transporter 2 (SGLT2) inhibitor that reduces hyperglycaemia in type 2 diabetes by promoting urinary glucose excretion. This study examined the effect of dapagliflozin on renal glucose kinetics in healthy subjects and subjects with type 2 diabetes.

**Materials and methods:** Renal glucose kinetics were assessed in 12 healthy control subjects (HbA1c 5.5 %, 41 years, 27 kg/m<sup>2</sup>, 7 male/5 female) and 12 subjects with type 2 diabetes (HbA1c 6.5%, 53 years, 30 kg/m<sup>2</sup>, 7 male/5 female). All subjects had an estimated glomerular filtration rate (eGFR) ≥ 60 and ≤ 160 mL/min-1.73 m<sup>2</sup> by the Modification of Diet in Renal Disease equation. Subjects underwent a combined pancreatic and stepped hyperglycaemic clamp at baseline and after 7 days of dapagliflozin 10 mg/day. The pancreatic/stepped hyperglycaemic clamp was performed with octreotide and basal insulin/glucagon/growth hormone replacement, and evaluated a plasma glucose range of 100–550 mg/dL. Subjects with type 2 diabetes continued on baseline therapy unless taking metformin, which was held for 48 h before the pancreatic stepped hyperglycaemic clamp. A model was developed to describe maximum tubular glucose transport (TmG), renal glucose threshold (for onset of glucosuria), and splay of the glucose titration curve for healthy and type 2 diabetes populations, and then used to estimate these parameters from individual titration curves.

**Results:** At baseline, the TmG (443 vs 326 mg/min,  $P < 0.04$ ) and splay (28,650 vs 14,248 mg<sup>2</sup>/min<sup>2</sup>,  $P < 0.0001$ ) were significantly higher in subjects with type 2 diabetes versus controls. The baseline threshold was similar in subjects with type 2 diabetes (196 mg/dL [10.9 mmol/L]) and controls (171 mg/dL [9.5

mmol/L]). Dapagliflozin treatment reduced TmG by 58% in type 2 diabetes subjects and 53% in healthy subjects. The splay declined similarly by ~37% for both groups. Following dapagliflozin, the modelled threshold was markedly reduced in type 2 diabetes patients, by 89% (21 mg/dL [1.2 mmol/L]) and in healthy controls, by 78% (37 mg/dL [2.1 mmol/L]). These modelled threshold values were well below the plasma glucose levels measured in this study. A modest reduction in GFR (~14%) was observed following dapagliflozin treatment in both groups.

**Conclusion:** In summary, type 2 diabetes subjects have a higher TmG and splay than healthy controls. Dapagliflozin treatment for 7 days reduced TmG and splay. However, the markedly decreased renal glucose threshold was the primary mechanism responsible for the induction of glucosuria with dapagliflozin in both subjects with type 2 diabetes and healthy controls.

### Dapagliflozin has no long-term effect on markers of bone turnover or bone mineral density in patients with inadequately controlled type 2 diabetes on metformin

Ö. Ljunggren<sup>1</sup>, J. Bolinder<sup>2</sup>, L. Johansson<sup>1,3</sup>, J.P.H. Wilding<sup>4</sup>, A.M. Langkilde<sup>3</sup>, C.D. Sjöström<sup>3</sup>, J. Sugg<sup>5</sup>, S. Parikh<sup>5</sup>

<sup>1</sup>Uppsala University, Sweden, <sup>2</sup>Karolinska Institute, Stockholm, Sweden,

<sup>3</sup>AstraZeneca, Mölndal, Sweden, <sup>4</sup>University of Liverpool, UK, <sup>5</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin, a selective inhibitor of sodium-glucose cotransporter 2 (SGLT2), reduces hyperglycaemia in patients with type 2 diabetes mellitus (T2DM) by increasing urinary glucose excretion. Owing to its renal tubular mechanism of action, and because small increases in serum magnesium, phosphorus and parathormone without changes in serum calcium have been noted in clinical trials of dapagliflozin, we evaluated markers of bone formation and resorption and bone mineral density (BMD) in patients whose T2DM was inadequately controlled on metformin after 102 weeks of dapagliflozin treatment.

**Materials and methods:** This international, multi-centre, randomised, parallel-group, double-blind, placebo-controlled study enrolled patients with T2DM (mean values: women 63.3 and men 58.6 years; HbA1c 7.17%; BMI 31.9 kg/m<sup>2</sup>; and body weight 91.5 kg) inadequately controlled on metformin. A total of 182 patients were randomly assigned 1:1 to receive dapagliflozin 10 mg/day or placebo added to open-label metformin for a 24-week double-blind treatment period followed by a 78-week site- and patient-blinded extension period. At week 102 the following safety variables were evaluated: serum markers of bone formation (procollagen type 1 N-terminal propeptide; P1NP) and resorption (C-terminal crosslinking telopeptides of type I collagen; CTX); BMD at lumbar spine (L1-4), femoral neck and total hip regions assessed using standardised dual-energy x-ray absorptiometry (DXA); and adverse events of fracture.

**Results:** A total of 140 (76.9%) patients completed the 102-week study. Dapagliflozin vs placebo difference in adjusted mean change from baseline at 102 weeks for body weight was -2.42 kg (95% CI -3.64, -1.21) and for HbA1c was -0.42% (95% CI -0.62, -0.22). Baseline HbA1c was 7.16% and 7.19% in the dapagliflozin vs placebo groups, respectively. At 102 weeks, no statistically significant dapagliflozin vs placebo differences were identified in mean changes from baseline in P1NP (1.16 µg/L,  $p = 0.4096$ ), CTX (0.01 µg/L,  $p = 0.6916$ ) or mean percent changes from baseline in BMD at lumbar spine (0.22,  $p = 0.7013$ ), femoral neck (-0.94,  $p = 0.1521$ ) or total hip (-0.45,  $p = 0.3105$ ) regions. Over 102 weeks, no dapagliflozin vs placebo differences in proportions of patients with a BMD decrease of ≥5% were evident in any anatomical region (Table). There were no clinically significant changes in serum calcium, parathormone or 25-OH vitamin D; however, serum inorganic phosphorus increased. One patient in each treatment group experienced a forearm fracture.

**Conclusion:** Compared with placebo, dapagliflozin had no effect on markers of bone formation and resorption or BMD after 102 weeks of treatment in patients whose T2DM was inadequately controlled on metformin.

### Influence of renal function on dapagliflozin pharmacokinetics and pharmacodynamics

S.C. Griffen, S. Kasichayanula, X. Liu, M. Pe Benito, M. Yao, F.P. LaCreta, M. Pfister, W.G. Humphreys, D.W. Boulton;  
Bristol-Myers Squibb, Princeton, USA.

**Background:** Dapagliflozin (DAPA), a selective inhibitor of the renal sodium glucose co-transporter 2 (SGLT2), improves hyperglycaemia by promoting urinary glucose excretion (UGE) proportional to the filtered load of glucose (plasma glucose × glomerular filtration rate [GFR]). The majority of DAPA is metabolised via glucuronidation by the enzyme UGT1A9 to the inactive metabolite, DAPA 3-O-glucuronide (D3OG), which is mainly cleared via renal excretion. As the kidney is the site of DAPA action, this open-label, parallel study was conducted to assess DAPA pharmacokinetics (PK), pharmacodynamics (PD), and safety in patients with type 2 diabetes (T2D) and renal impairment.

**Methods:** Patients with T2D and normal renal function or mild, moderate, or severe renal impairment (creatinine clearance of 51–80, 30–50, and < 30 mL/min excluding patients on dialysis, respectively) and healthy subjects received single (50 mg) and subsequent multiple (20 mg/day for 7 days - T2D patients only) doses of DAPA. Background antihyperglycaemic medications, excluding exenatide, were allowed.

**Results:** The PK profile of a single dose of DAPA 50 mg was similar in healthy subjects and patients with T2D and normal renal function. Exposure to DAPA and D3OG was incrementally higher with decreasing renal function (Table). After 7 days of DAPA 20 mg/day, steady-state C<sub>max</sub> values and systemic exposure for DAPA and D3OG were incrementally higher with decreasing renal function compared to patients with T2D and normal renal function. An in vitro study of isolated human kidney microsomes showed higher UGT1A9 activity and D3OG formation rate relative to human liver and intestinal microsomes (3- and 109-fold higher, respectively). Renal glucose clearance values were 53%, 77%, and 85% lower in T2D patients with mild, moderate, and severe renal impairment, respectively, compared to subjects with normal renal function. The corresponding steady-state glucose clearance values, with DAPA 20 mg/day for 7 days, were 42%, 83%, and 84% lower. Mean 24-h urinary glucose excretion and changes in fasting serum glucose were similarly reduced with increasing degrees of renal impairment. There were no marked differences in serum electrolytes, including sodium, between groups at baseline or after treatment. DAPA was well tolerated, with no discontinuations.

**Conclusions:** These findings indicate that a substantial proportion of DAPA metabolism occurs via UGT1A9 in the kidney resulting in higher systemic exposures of dapagliflozin in patients with renal impairment compared to those with normal renal function. The PD effects of DAPA are reduced as renal function decreases, despite higher systemic DAPA exposure, due to a decreased GFR and subsequent decrease in filtered glucose load. These results suggest that DAPA may have reduced efficacy in patients with moderate to severe renal dysfunction.

	Classification of renal impairment	DAPA 50 mg - single dose		DAPA 20 mg - 7 days	
		C <sub>max</sub>	AUC <sub>0-τ</sub>	C <sub>max</sub>	AUC <sub>0-τ</sub>
DAPA	Mild	14%	25%	4%	32%
	Moderate	26%	46%	6%	60%
	Severe	36%	65%	9%	87%
D3OG	Mild	20%	47%	20%	54%
	Moderate	36%	93%	37%	110%
	Severe	51%	140%	52%	169%

Data are geometric means derived from model-based linear regression of observed data values. Values represent percent increase in comparison to normal renal function for the midpoint of each renal impairment category.

### Measures of beta cell function and insulin sensitivity over time in patients with type 2 diabetes receiving dapagliflozin versus glipizide as add-on therapy to metformin

A. Langkilde<sup>1</sup>, K. Rohwedder<sup>2</sup>, N. Iqbal<sup>3</sup>, L. Ying<sup>3</sup>, A. Salsali<sup>3</sup>;

<sup>1</sup>AstraZeneca, Mölndal, Sweden, <sup>2</sup>AstraZeneca, Wedel, Germany, <sup>3</sup>Bristol-Myers Squibb, Princeton, USA.

**Background and aims:** Dapagliflozin (DAPA), a selective inhibitor of sodium glucose co-transporter 2 (SGLT2), reduces plasma glucose and promotes weight loss by increasing renal glucose excretion. By this mechanism, DAPA has the potential to be disease modifying and to affect the underlying pathophysiology of type 2 diabetes. Here we evaluate the effect of DAPA on  $\beta$ -cell function and insulin sensitivity in comparison to glipizide (GLIP) as add-on therapy to metformin.

**Materials and methods:** In this 52-wk study (N=814 [636 completers]) with a 52-wk extension (N=624 [432 completers]), patients with type 2 diabetes (mean baseline HbA1c = 7.7%, diabetes duration = 6.3 y) inadequately controlled with metformin (1500–2500 mg/day) received DAPA ( $\leq 10$  mg/day) or GLIP ( $\leq 20$  mg/day) as add-on therapy. Adjusted mean change from baseline (95% CI) in fasting insulin, proinsulin, C-peptide, homeostatic model assessment-2 $\beta$  (HOMA-2  $\beta$ ) (% $\beta$ ), and HOMA-2 insulin sensitivity was evaluated at wks 26, 52, 78, and 104 using longitudinal repeated measures analysis.

**Results:** The primary end point, adjusted mean change from baseline in HbA1c at week 52, was identical for DAPA and GLIP, -0.52%. At 104 wks, mean HbA1c (95% CI) was reduced more with DAPA, -0.32% (-0.42%, -0.21%) than with GLIP, -0.14% (-0.25%, -0.03%). Mean changes in fasting plasma glucose (95% CI) for DAPA and GLIP were -23.1 (-26.6, -19.9) and -19.0 (-22.3, -15.8) mg/dL at wk 52 and -20.2 (-23.8, -16.5) and -12.2 (-15.9, -8.5) mg/dL at wk 104, respectively.  $\beta$ -Cell function and insulin sensitivity were assessed by fasting insulin, proinsulin, and C-peptide levels and by HOMA-2, which has not been validated in the setting of urinary glucose loss with SGLT2 inhibitors. Fasting insulin decreased with DAPA at wk 52, -1.64 (-2.47, -0.82) and 104, -2.35 (-3.86, -0.85)  $\mu$ U/L, but increased with GLIP, 1.28 (0.44, 2.12) and 1.16 (-0.42, 2.74)  $\mu$ U/L. Proinsulin decreased at wk 52, -5.94 (-7.89, -3.99) and 104, -5.46 (-7.52, -3.39) pmol/L with DAPA and increased with GLIP, 5.32 (3.35, 7.29) and 4.74 (2.61, 6.88) pmol/L. C-peptide did not change with DAPA at wk 52, -0.08 (-0.20, 0.03) or wk 104, -0.14 (-0.28, -0.01) ng/mL, but increased with GLIP, 0.48 (-0.36, 0.59) and 0.35 (0.21, 0.49) ng/mL. HOMA-2 % $\beta$  increased more with GLIP, 28.7% (24.5%, 33.0%) than with DAPA, 15.0% (10.8%, 19.2%) at wk 52 and at wk 104, 18.0% (13.3%, 22.8%) for GLIP vs 11.6% (7.1%, 16.2%) for DAPA. GLIP decreased HOMA-2 insulin sensitivity at wk 52, -4.0% (-6.0%, -2.0%) and 104, -1.4% (-4.4%, 1.6%), whereas DAPA increased HOMA-2 insulin sensitivity at wk 52, 6.0% (4.0%, 8.0%) and 104, 6.5% (3.6%, 9.4%).

**Conclusions:** DAPA showed a greater durability of glycaemic control than GLIP and lowered fasting proinsulin. Patients receiving DAPA exhibited improvement of  $\beta$ -cell function and improvement of insulin sensitivity, while GLIP also showed improvement of  $\beta$ -cell function however worsening of insulin sensitivity.

### Dapagliflozin produces long-term reductions in body weight, waist circumference and total fat mass in patients with type 2 diabetes inadequately controlled on metformin

J. Bolinder<sup>1</sup>, Ö. Ljunggren<sup>2</sup>, L. Johansson<sup>2,3</sup>, J.P.H. Wilding<sup>4</sup>, A.M. Langkilde<sup>3</sup>, C.D. Sjöström<sup>3</sup>, J. Sugg<sup>5</sup>, S. Parikh<sup>5</sup>;

<sup>1</sup>Karolinska Institute, Stockholm, Sweden, <sup>2</sup>Uppsala University, Sweden, <sup>3</sup>AstraZeneca, Mölndal, Sweden, <sup>4</sup>University of Liverpool, UK, <sup>5</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin, a selective inhibitor of sodium-glucose cotransporter 2 (SGLT2), reduces hyperglycaemia in patients with type 2 diabetes mellitus (T2DM) by increasing urinary glucose excretion. Weight loss has been a consistent associated finding. A previous report demonstrated reduced total body weight (TBW) at 24 weeks (dapagliflozin vs placebo difference -2.08 kg; 95% CI -2.84, -1.31), principally accounted for by reduced fat mass (dapagliflozin vs placebo difference -1.48 kg; 95% CI -2.22, -0.74). Here we investigated whether these reductions were maintained after a further 78 weeks of dapagliflozin treatment.

**Materials and methods:** This international, multi-centre, randomised, parallel-group, double-blind, placebo-controlled study enrolled patients with T2DM (mean values: women 63.3 and men 58.6 years; HbA1c 7.17%; BMI 31.9 kg/m<sup>2</sup>; and body weight 91.5 kg) inadequately controlled on metformin. A total of 182 patients were randomised 1:1 to receive dapagliflozin 10 mg/day or placebo added to open-label metformin for a 24-week double-blind treatment period followed by a 78-week site- and patient-blinded extension period. Patients received rescue therapy with sitagliptin 100 mg if their HbA1c was  $>8.0\%$  from week 24 to 50 and  $>7.5\%$  from week 50 to 102. The main objectives were to assess TBW, waist circumference and dual-energy x-ray absorptiometry total-body fat mass changes from baseline at week 102, and the proportion of patients achieving a body weight reduction of  $\geq 5\%$  at week 102. **Results:** A total of 140 (76.9%) patients completed the 102-week study. Dapagliflozin vs placebo differences were as follows: TBW, -2.42 kg (95% CI -3.64, -1.21); waist circumference, -2.1 cm (95% CI -3.9, -0.3); fat mass, -1.34 kg (95% CI -2.44, -0.23); proportion of patients achieving weight reduction of  $\geq 5\%$ , 10.6% (95% CI -1.4, 22.6). At 102 weeks, dapagliflozin maintained both urinary glucose excretion and reductions in HbA1c and fasting plasma glucose with a lower proportion of patients requiring rescue therapy or discontinuing due to poor glycaemic control (Table). By 102 weeks, in the dapagliflozin vs placebo groups, respectively, adverse events were reported in 71.4 vs 69.2%; events of vulvovaginitis, balanitis, and related genital infection in 2.2 vs 1.1%; events of urinary tract infection in 6.6 vs 7.7%; and hypoglycaemic episodes in 4.4 vs 5.4%.

**Conclusion:** Dapagliflozin produces long-term reductions in TBW, fat mass and waist circumference in the context of sustained improvements in glycaemic control compared with placebo in T2DM patients inadequately controlled with metformin. On-going caloric loss from increased urinary glucose excretion with dapagliflozin is likely to have accounted for these long-term changes in TBW and fat mass.

**Dapagliflozin corrects plasma glucose levels after acute and chronic treatment: a mechanistic examination of glucose fluxes and transcription profiles**

B. Zinker, X. Ma, H. Liu, C. Cai, R. Ponticello, J. Zalaznick, B. Guan, W.-P. Yang, V. Patel, A. He, J. Chen, J. Whaley; Bristol-Myers Squibb, Princeton, USA.

**Background and aims:** Dapagliflozin (Dapa) is a potent ( $K_i=0.55$  nM), selective SGLT2 inhibitor (>1400-fold vs SGLT1) which reduces renal glucose reabsorption and may provide an insulin-independent mechanism for type 2 diabetes treatment. Dapa reduces hyperglycemia acutely and prevents progression to the diabetic state during chronic dosing in male ZDF rats without hypoglycemia. To examine the impact of Dapa treatment on  $\beta$ -cell insulin content and function, as well as endogenous glucose production and disposal, prediabetic male ZDF rats and their lean littermates were used in acute and chronic studies. Liver, adipose, skeletal muscle and kidney gene transcription profiles were also evaluated following chronic treatment.

**Materials and methods:** Male ZDF and lean rats at 11 wk of age were dosed acutely with vehicle (Vh) or Dapa at 0.5 or 1.0 mg/kg, and studied over a 2 hr period in which whole body glucose fluxes were examined. For the chronic study rats began treatment (*q.d.*, *p.o.*) prior to frank diabetes (6 wk of age) which continued to 11 wk of age with either Vh (lean and male ZDF) or 0.5 mg/kg Dapa (male ZDF). At 48 hr after the last dose, a euglycemic-hyperinsulinemic clamp was performed and tissues were harvested for mRNA expression.

**Results:** Acute Arterial plasma glucose levels decreased (30 min) and stabilized (90 min) in male ZDF rats following both Dapa doses, while Vh and Lean Dapa glucose levels were unchanged. In lean rats Dapa was associated with a dose-dependent increase in glucose production (rate of appearance [Ra];  $9.8 \pm 0.5$  vs  $6.5 \pm 0.4$  mg/kg-min, 1.0 mg/kg vs Vh,  $p < 0.001$ ). By comparison, in male ZDF rats 1.0 mg/kg was associated with increased Ra ( $13.5 \pm 0.6$  mg/kg-min;  $p < 0.01$ ) vs Vh. Dapa was associated with decreased glucose utilization (GUR) in Lean at 0.5 mg/kg, and diminished GUR in a non-dose-dependent manner in ZDF rats vs Vh due to urine glucose loss. Chronic: Dapa maintained plasma glucose and  $HbA_{1c}$  to levels near those in Vh Lean, and decreased basal glucose flux vs that seen in the ZDF Vh ( $6.6 \pm 0.4$  vs  $9.3 \pm 0.8$  mg/kg-min,  $p = 0.01$ ). Pancreatic insulin content was maintained at baseline levels, and plasma insulin levels were increased, with Dapa vs the declines in ZDF Vh, respectively, after 5 wks. During the clamp, whole body glucose disposal and glucose uptake in epididymal fat and soleus muscle were similar in the Dapa and Vh ZDF groups. Dapa increased glucose infusion rate ( $8.8 \pm 0.7$  vs  $3.8 \pm 0.6$  mg/kg-min,  $p < 0.05$ ), and decreased endogenous glucose production on an absolute ( $3.6 \pm 0.5$  vs  $10.7 \pm 2.1$  mg/kg-min,  $p < 0.001$ ) and relative basis vs ZDF Vh ( $-45 \pm 9\%$  vs  $20 \pm 28\%$ ,  $p < 0.05$ ). Transcription profiling revealed liver to have the greatest changes in gene expression; Dapa treatment resulted in significant increases in SCD1, GCK, INHBC mRNA and decrease in HSD11b1 mRNA. No change in expression of renal glucose transporters was observed in the kidney suggesting there is little renal glucose transporter transcriptional compensation for SGLT2 inhibition in this model. No significant enhancement of cellular proliferation or tumor promotor-related expression was observed in any tissue examined.

**Conclusion:** Acute Dapa treatment leads to dose-dependent increases in endogenous glucose production and decreases plasma glucose in hyperglycemic rats without hypoglycemia.

**Long-term effectiveness of dapagliflozin over 104 weeks in patients with type 2 diabetes poorly controlled with insulin**

K. Rohwedder<sup>1</sup>, J.P.H. Wilding<sup>2</sup>, V. Woo<sup>3</sup>, J. Sugg<sup>4</sup>, S. Parikh<sup>4</sup>;

<sup>1</sup>AstraZeneca, Wedel, Germany, <sup>2</sup>University of Liverpool, UK, <sup>3</sup>University of Manitoba, Winnipeg, Canada, <sup>4</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin, a sodium-glucose cotransporter 2 (SGLT2) inhibitor, increases urinary glucose excretion and reduces hyperglycaemia in type 2 diabetes (T2DM) independent of insulin secretion or action.

**Materials and methods:** We report results after 104 weeks of patient- and centre-blinded treatment in patients with T2DM poorly controlled on insulin ( $n=808$ ; mean baseline  $HbA_{1c}$  8.53%) randomised to receive placebo, or dapagliflozin 2.5, 5 or 10 mg/day added to background insulin (mean baseline insulin 77 IU/day)  $\pm$  oral glucose-lowering drugs. Analyses at 24 weeks

(primary endpoint) and at 48 weeks were reported previously. At 48 weeks, patients on dapagliflozin 5 mg were switched to 10 mg (5/10-mg group). Insulin was uptitrated if  $HbA_{1c}$  was  $>7.5\%$  from 52 to 65 weeks or  $>7.0\%$  from 78 to 104 weeks. 63.6% of patients completed 104 weeks. Analyses over 104 weeks used observed cases and included data after insulin uptitration.

**Results:** Mean  $HbA_{1c}$  changes from baseline at 104 weeks were  $-0.43\%$  in the placebo group and  $-0.64\%$  to  $-0.82\%$  in the dapagliflozin groups (corresponding  $HbA_{1c}$  values excluding data after insulin uptitration were  $-0.06\%$  vs  $-0.49\%$  to  $-0.71\%$ ). In the placebo group, mean insulin dose increased by 18.3 IU/day and weight increased by 1.8 kg at 104 weeks, whereas in the dapagliflozin groups, insulin dose was stable and weight decreased by 0.9 to 1.4 kg (weight values excluding data after insulin uptitration were  $+0.91$  kg in the placebo group vs  $-1.47$  to  $-1.97$  kg in the dapagliflozin groups). Adverse events, including hypoglycaemia, were balanced across groups (Table). Proportions of patients with events suggestive of genital infection and of urinary tract infection (UTI) were higher with dapagliflozin vs placebo (genital infection 7.4 to 14.3% vs 3.0%; UTI 8.4 to 13.8% vs 5.6%) but most occurred in the first 24 weeks and most were single episodes that responded to routine management.

**Conclusion:** Dapagliflozin treatment over 104 weeks in patients with T2DM poorly controlled on insulin was well tolerated and resulted in reductions in  $HbA_{1c}$  and weight without an increase in mean daily insulin requirements.

Efficacy and safety of dapagliflozin at 104 weeks in patients with T2DM poorly controlled on insulin

**Glycaemic and weight-reduction benefits with dapagliflozin in patients with type 2 diabetes mellitus: pooled subgroup analysis of nine clinical trials**T.A. Mansfield<sup>1</sup>, T. de Bruin<sup>2</sup>, E. Hardy<sup>2</sup>, A. Salsali<sup>3</sup>, L. Wei<sup>3</sup>, C. Wessman<sup>4</sup>, S. Parikh<sup>2</sup>;<sup>1</sup>Bristol-Myers Squibb, Princeton, USA, <sup>2</sup>AstraZeneca, Wilmington, USA, <sup>3</sup>Research & Development, Bristol-Myers Squibb, Princeton, USA,<sup>4</sup>AstraZeneca, Mölndal, Sweden.

**Background and aims:** Reduction of glycaemic levels and body weight are fundamental goals in management of patients with type 2 diabetes mellitus (T2DM). Dapagliflozin is a selective inhibitor of sodium glucose cotransporter 2 (SGLT2) that reduces plasma glucose independently of insulin secretion or action by increasing the urinary excretion of excess glucose. This report analyzed the effect of dapagliflozin on HbA1c and weight from data pooled from nine double-blind, randomized clinical trials of dapagliflozin in patients with T2DM to determine if improvements in these outcomes are dependent on baseline parameters.

**Materials and methods:** Patients with T2DM (N=4047) received daily doses of dapagliflozin 2.5 mg, 5 mg, or 10 mg or placebo for 24 weeks as monotherapy; as add-on to metformin, glimepiride, pioglitazone, or insulin; or as initial combination with metformin. Adjusted mean change from baseline in HbA1c, excluding data after rescue (LOCF), was analyzed by an ANCOVA model with treatment group, subgroup, and study as categorical factors; and interaction between treatment group and subgroup, baseline HbA1c and weight, and study-by-baseline interaction with HbA1c and weight as continuous covariates. Treatment by subgroup interactions were analyzed for baseline HbA1c, estimated glomerular filtration rate (eGFR), age, gender, race, ethnicity (US only), geographic region, BMI, and T2DM duration. *P* values are reported for subgroup interaction based on average treatment effect relative to placebo; a *P* value <0.1 indicated a potential interaction.

**Results:** Control-corrected mean changes from baseline in the individual studies for HbA1c in the dapagliflozin treatment groups (range, %) were: monotherapy -0.35 to -0.84, add-on metformin -0.28 to -0.54, add-on glimepiride -0.44 to -0.68, add-on pioglitazone -0.40 to -0.55, add-on insulin -0.45 to -0.60, and initial combination with metformin -0.54 to -0.70. No interaction of change from baseline in HbA1c was detected for gender, race, ethnicity, region, BMI, or T2DM duration. Potential subgroup interactions were detected for baseline HbA1c (*P*<0.0001), eGFR category (*P*=0.015), and age (*P*=0.054). After controlling for eGFR, age was no longer a factor affecting efficacy. In the analysis of body weight, placebo-corrected change from baseline ranged from -0.46 to -2.16 kg in the overall population. No subgroup interactions of weight reduction with age, gender, baseline HbA1c, BMI, eGFR, or duration of T2DM were detected; potential subgroup interactions were detected for geographic region (*P*=0.03), race (*P*=0.06), and ethnicity (*P*=0.09). **Conclusion:** Dapagliflozin provides consistent reductions in HbA1c and body weight across a range of subgroups of patients with T2DM. The magnitude of the reduction in HbA1c is influenced by baseline HbA1c and eGFR, as expected given the dependence of the MOA of dapagliflozin on the renal filtration of glucose. Additional benefits in body weight reduction appear to be independent of age, gender, baseline HbA1c, BMI, eGFR, and duration of diabetes.

## 755

**Dapagliflozin is more effective than glipizide in achieving the composite outcome of glycaemic control, weight reduction and lack of hypoglycaemia**G.D. Wygant<sup>1</sup>, A.-G. Chalamandaris<sup>2</sup>, U.H. Illoeje<sup>3</sup>, A. Salsali<sup>1</sup>, S. Grandy<sup>4</sup>, J.E. Sugg<sup>4</sup>, K. Rohwedder<sup>5</sup>, S.J. Parikh<sup>4</sup>;<sup>1</sup>Bristol-Myers Squibb, Princeton, USA, <sup>2</sup>Bristol-Myers Squibb, Braine-l'Alleud, Belgium, <sup>3</sup>Bristol-Myers Squibb, Wallingford, USA, <sup>4</sup>AstraZeneca, Wilmington, USA, <sup>5</sup>AstraZeneca, Wedel, Germany.

**Background and aims:** Management of diabetes often results in trade-offs between glycaemic control and untoward effects of weight gain and hypoglycaemic events. Dapagliflozin (DAPA), a selective sodium-glucose cotransporter 2 (SGLT2) inhibitor, reduces hyperglycaemia and body weight with

a low risk of hypoglycaemia by increasing urinary glucose excretion in an insulin-independent manner. Key results of a randomised, double-blind trial of DAPA (up to 10 mg/d, n=400) vs glipizide (GLIP, up to 20 mg/d, n=401) as add-on therapies to metformin (MET, median 2000 mg/d) in subjects with T2DM inadequately controlled on MET (mean baseline HbA1c 7.72%), have been published elsewhere. Overall, 77.9% of randomised patients (322 in the DAPA group and 314 in the GLIP group) completed the study. This post-hoc analysis assessed the proportion of subjects achieving the clinically relevant composite endpoint of HbA1c <7%, no major or minor hypoglycaemic (hypo) events and weight loss ≥ 3%.

**Materials and methods:** Proportion with HbA1c <7% at 52 weeks (LOCF) was evaluated; subjects with HbA1c <7% at baseline were excluded (21% in DAPA + MET [84/400] arm and 19% in GLIP + MET [78/401] arm). Major/minor hypo events included those with onset on/after first day of double blind treatment and on/prior to last day of short-term treatment + 4 days. Proportion of patients with total body weight reduction of ≥ 3% from baseline to week 52 LOCF was calculated. Confidence intervals (CI) for the difference between study arms were calculated using the exact method.

**Results:** At 52 weeks, the composite endpoint was achieved by 20.6% of subjects in the DAPA + MET arm (65/316) versus 1.9% in the GLIP + MET (6/323) arm. The difference of DAPA + MET versus GLIP + MET was 18.7% (95% CI: 14.3%, 23.8%).

**Conclusion:** More subjects treated with DAPA + MET achieved the composite endpoint of HbA1c <7%, no major or minor hypoglycaemic events and ≥ 3% weight loss at 1 year compared with subjects treated with GLIP + MET. These results demonstrate that DAPA, with its insulin-independent mechanism of action of increased urinary glucose excretion, can positively impact key treatment parameters while avoiding hypoglycaemia. \*Affiliation at the time of writing

## 756

**Dapagliflozin treatment for type 2 diabetes mellitus patients with a history of cardiovascular disease**L. Leiter<sup>1</sup>, W. Cefalu<sup>2</sup>, T. DeBruin<sup>3</sup>, I. Gause-Nilsson<sup>4</sup>, J. Sugg<sup>3</sup>, S. Parikh<sup>3</sup>;<sup>1</sup>University of Toronto, Canada, <sup>2</sup>University of Louisiana, Baton Rouge, USA,<sup>3</sup>AstraZeneca, Wilmington, USA, <sup>4</sup>AstraZeneca, Mölndal, Sweden.

**Background and aims:** Dapagliflozin (DAPA) is a selective SGLT2 inhibitor with glucuretic effects under investigation for the treatment of type 2 diabetes mellitus (T2DM). DAPA-induced urinary glucose excretion results in improved glycaemic control and body weight (BW) loss. Here we present the results of 1 of 2 phase 3 trials conducted to assess DAPA efficacy and safety in patients with T2DM and documented cardiovascular disease (CVD).

**Materials and methods:** Patients (N=964) with HbA1c ≥7.0%–≤10.0%, were randomised to receive double-blind DAPA 10 mg/d or placebo (PBO) for 24 wks (2 extensions ongoing adding up to 80 wks) and stratified by age (<65 or ≥65 y), insulin (INS) use, and time from most recent qualifying CV event. INS doses were reduced by 25% at randomisation. The co-primary end points were change from baseline (BL) in HbA1c and the proportion of patients achieving a 3-item composite end point: reduction of ≥0.5% in HbA1c, ≥3% in BW, and ≥3 mmHg in seated systolic blood pressure (SBP).

**Results:** The mean age was 64 y, and 47% were ≥65 y. Mean T2DM duration was 13 y. Most patients reported the use of 1–2 oral anti-hyperglycaemic agents. Twenty percent received only INS, and an additional 41% used INS in combination with other treatments. A history of hypertension was present in 93% of patients. Reductions from BL were greater for DAPA vs PBO in HbA1c (BL 8.1%) and SBP (BL 134.7 mmHg) (Table). More DAPA patients achieved the 3-item end point vs PBO. BW (BL 93.9 kg) was significantly reduced for DAPA vs PBO, and more patients in the DAPA group achieved a ≥3% decrease in BW. In patients with BL body mass index ≥27 kg/m<sup>2</sup> (88%), a greater proportion achieved weight loss of ≥5% in the DAPA vs PBO group (18.4% vs 4.8%, *P*<0.0001). In those receiving INS, the mean daily INS dose increased 10% (5.3 IU/d) with PBO vs no change with DAPA (-0.0 IU/d, nominal *P*<0.05). Stratified analyses yielded similar results to the overall analysis; however, SBP reduction was not significantly different at 24 wks in patients ≥65 y. Adverse events (AEs) and serious AEs were balanced between groups, but more patients on DAPA had events suggestive of vulvovaginitis/balanitis or urinary tract infection. Hypoglycaemia was observed more often in those patients on INS at randomisation and for a slightly higher proportion of patients in the DAPA group vs the PBO group (21.0% vs 17.4%). Unadjusted adverse CV events (DAPA 4.4% vs PBO 5.2%) and serious CV

events (DAPA 2.7% vs PBO 2.3%) were reported for similar proportions of patients in both groups.

**Conclusion:** When added to standard of care, DAPA improved glycaemic control with a low incremental risk of hypoglycaemia, was associated with BW loss and lowering of BP, and was well tolerated in an older, high CV risk population with advanced T2DM and comorbid CVD. The BW loss accompanying DAPA treatment suggests an added health benefit beyond glycaemic control for a predominantly overweight population.

### Dapagliflozin pharmacokinetic and pharmacodynamic relationships in patients with type 2 diabetes and healthy subjects: a meta-analysis of 9 clinical studies

D.W. Boulton, X. Liu, M. Hesney, S.C. Griffen, F.P. LaCreta, S. Kasichayanula; Bristol-Myers Squibb, Princeton, USA.

**Background and aims:** Dapagliflozin (DAPA), a potent, highly-selective, orally active inhibitor of the human renal sodium glucose co-transporter (SGLT2), is being developed for the treatment of type 2 diabetes mellitus (T2DM).

**Materials and methods:** DAPA pharmacokinetic (PK) parameters and pharmacodynamic (PD) endpoints (renal glucose clearance (CL<sub>Rgl</sub>) and 24-h urinary glucose amount (Ae<sub>gl</sub>) were pooled from 9 Clinical Pharmacology studies in subjects with normal renal function (n=270; 179 healthy subjects (HS) and 81 patients with T2DM). To assess the proportionality of DAPA PK parameters (C<sub>max</sub> and AUC) to dose, linear regression analyses of log(C<sub>max</sub>) on log(dose) and of log(AUC) on log(dose) were performed using a power model. A sigmoid maximum effect (E<sub>max</sub>) model was used to assess the relationship between DAPA dose or exposure and urinary PD including change from baseline in 24-hr Ae<sub>gl</sub> and CL<sub>Rgl</sub>.

**Results:** DAPA C<sub>max</sub> and AUC values increased proportionally to DAPA dose from 0.1 mg (lowest dose with definable PK) up to 500 mg (highest dose studied), and no clear differences were observed between HS and patients with T2DM. Dose-related increases in 24 h Ae<sub>gl</sub> was observed following the administration of DAPA doses ≥ 0.3 mg, and maximal increases in Ae<sub>gl</sub> were observed at doses ≥ 20 mg/day. Patients with T2DM had greater Ae<sub>gl</sub> compared to HS (E<sub>max</sub>: 83 and 66 g/24 h, respectively, and the doses for which one-half of E<sub>max</sub> was predicted (ED<sub>50</sub>) were 4.0 and 4.7 mg for healthy subjects and patients with T2DM, respectively). CL<sub>Rgl</sub> was not different between HS and patients with T2DM.

**Conclusion:** DAPA PK were linear over a wide dose range (0.3–500 mg) and were not different between HS, and patients with T2DM. The Ae<sub>gl</sub> was higher in patients with T2DM compared to HS due to their higher plasma or serum glucose concentrations, resulting in a greater amount of glucose being renally filtered. CL<sub>Rgl</sub> was not different between these populations.

### Dapagliflozin is safe and effective as add on therapy to sitagliptin with or without background metformin

S. Jabbour<sup>1</sup>, E. Hardy<sup>2</sup>, J. Sugg<sup>2</sup>, S. Parikh<sup>2</sup>;

<sup>1</sup>Jefferson Medical College of Thomas Jefferson University, Philadelphia,

<sup>2</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin is a selective sodium glucose co-transporter 2 (SGLT2) inhibitor in development for the treatment of type 2 diabetes.

Dapagliflozin reduces hyperglycaemia through the inhibition of filtered glucose reabsorption resulting in an increase in urinary glucose excretion.

**Materials and methods:** In this 24-week, randomised, double-blind, placebo controlled study with a 24-week blinded extension period, 452 patients with inadequate glycaemic control on a stable DPP-4 inhibitor with or without metformin received dapagliflozin 10 mg QD or placebo plus sitagliptin (100mg QD: Stratum 1) or sitagliptin plus metformin (≥ 1500 mg QD: Stratum 2).

**Results:** Baseline (BL) HbA1c, fasting plasma glucose (FPG) and body weight values for placebo and dapagliflozin were 7.97% and 7.90%, 9.06 mmol/L [163mg/dL] and 9.00 mmol/L [162 mg/dL], and 89 kg and 91 kg respectively. At week 24 significant improvements were observed with dapagliflozin versus placebo (LOCF, P<0.0001) in each of the 3 variables. Whether the data after rescue were excluded or included, glycaemic and weight benefits that were observed at week 24 were maintained through week 48 in the overall data set and in each stratum (Table shows values excluding rescue). Over 48 weeks 31.8% of subjects receiving dapagliflozin were discontinued or rescued for failing to achieve glycaemic targets compared to 56.6% with placebo. Adverse events (AEs) were slightly more frequent in the dapagliflozin group (24 weeks: placebo - 109 subjects [48.2%], dapagliflozin - 119 subjects [52.9%]; 48 weeks: placebo - 138 [61.1%], dapagliflozin - 149 [66.2%]); discontinuations as a result of AEs were infrequent and balanced (24 weeks: placebo - 5 [2.2%]; dapagliflozin - 7 [3.1%]; 48 weeks: placebo - 7 [3.1%]; dapagliflozin - 7 [3.1%]). At week 24, events of genital infections and urinary tract infection were more frequent with dapagliflozin (9.3% and 5.8%) than with placebo (0.4% and 3.5%).

**Conclusion:** Dapagliflozin is safe and effective in lowering blood glucose and body weight in patients inadequately controlled with sitagliptin with or without metformin at Week 24 and efficacy was maintained over 48 weeks.

### Canagliflozin, a sodium glucose co-transporter 2 inhibitor, improves glycaemic control and is well tolerated in type 2 diabetes subjects with moderate renal impairment

J.-F. Yale<sup>1</sup>, G. Bakris<sup>2</sup>, E. Wajsb<sup>3</sup>, L. Xi<sup>4</sup>, K. Figueroa<sup>5</sup>, K. Usiskin<sup>5</sup>, G. Meininger<sup>5</sup>;<sup>1</sup>Royal Victoria Hospital and McGill University, Montreal, Canada,<sup>2</sup>University of Chicago Pritzker School of Medicine, Chicago, USA, <sup>3</sup>Janssen Research & Development, Beerse, Belgium, <sup>4</sup>Janssen Biotech, Inc, Spring House, USA, <sup>5</sup>Janssen Research & Development, L.L.C., Raritan, USA.

**Background and aims:** Canagliflozin (CANA), a sodium glucose co-transporter 2 inhibitor, lowers plasma glucose by increasing urinary glucose excretion. This randomised, double-blind, placebo (PBO)-controlled, Phase 3 study evaluated the efficacy and safety of CANA in subjects with type 2 diabetes mellitus (T2DM) and moderate renal impairment.

**Materials and methods:** Subjects with T2DM (N = 269) who had moderate renal impairment (estimated glomerular filtration rate [eGFR])  $\geq 30$  and  $< 50$  mL/min/1.73 m<sup>2</sup> received CANA 100 or 300 mg or PBO once daily. Efficacy endpoints were assessed at Week 26 and adverse events (AEs) were recorded throughout the study. Renal safety parameters were also evaluated.

**Results:** Mean baseline characteristics were similar across groups (age, 68.5 years; HbA<sub>1c</sub>, 8.0%; body weight, 91.2 kg; body mass index, 33.0 kg/m<sup>2</sup>; eGFR, 39.4 mL/min/1.73 m<sup>2</sup>); median baseline albumin/creatinine ratio (ACR) was 30.0 µg/mg. 74.0% of subjects were on insulin and 31.2% were on a sulphonylurea. As shown in the Table, HbA<sub>1c</sub> was significantly decreased at Week 26 with CANA 100 and 300 mg compared with PBO ( $P < 0.05$  for both). Both CANA doses showed numerical improvements in fasting plasma glucose (FPG) and reductions in body weight and systolic blood pressure (BP) compared with PBO. More PBO-treated subjects received rescue therapy (14.4%) than with CANA 100 or 300 mg (4.4% and 3.4%, respectively).

**Table. Summary of Efficacy Endpoints at Week 26 (LOCF)**

Parameter, mean (SE) <sup>a,b</sup>	CANA 100 mg (N = 90)	CANA 300 mg (N = 89)	PBO (N = 90)
HbA <sub>1c</sub> change, %	-0.33 (0.09)	-0.44 (0.09)	-0.03 (0.09)
Difference vs PBO	-0.30 (0.12) <sup>c</sup>	-0.40 (0.12) <sup>c</sup>	
FPG change, mmol/L	-0.8 (0.3)	-0.7 (0.3)	0.03 (0.28)
Difference vs PBO	-0.9 (0.4)	-0.7 (0.4) <sup>*</sup>	
Body weight % change	-1.2 (0.3)	-1.5 (0.3)	0.3 (0.3)
Difference vs PBO	-1.6 (0.4)	-1.8 (0.4)	
Systolic BP change, mmHg	-6.1 (1.5)	-6.4 (1.5)	-0.3 (1.5)
Difference vs PBO	-5.7 (1.9)	-6.1 (2.0)	
Diastolic BP change, mmHg	-2.6 (0.9)	-3.5 (0.9)	-1.4 (0.9)
Difference vs PBO	-1.2 (1.1)	-2.1 (1.1)	
Triglycerides % change	6.2 (4.6)	11.9 (4.6)	7.9 (4.8)
Difference vs PBO	-1.7 (6.2)	3.9 (6.1)	
LDL-C % change	6.4 (3.5)	-1.0 (3.4)	6.3 (3.6)
Difference vs PBO	0.1 (4.6)	-7.2 (4.6)	
HDL-C % change	4.0 (1.7)	3.0 (1.7)	1.5 (1.8)
Difference vs PBO	2.5 (2.3)	1.5 (2.3)	
LDL-C/HDL-C % change	4.7 (3.7)	-4.3 (3.7)	4.7 (3.8)
Difference vs PBO	0.0 (4.9)	-8.9 (4.9)	

LOCF, last observation carried forward; SE, standard error; LDL-C, low-density lipoprotein cholesterol; HDL-C, high-density lipoprotein cholesterol; ANCOVA, analysis of covariance; NS, not significant. <sup>a</sup>Least squares mean (SE) change from baseline using ANCOVA; <sup>b</sup>P values are reported for pre-specified comparisons only; <sup>c</sup> $P < 0.05$  vs PBO; <sup>d</sup> $P < 0.001$  vs PBO; <sup>e</sup> $P = NS$  vs PBO; additional testing was not performed due to multiplicity control.

The overall incidence of AEs was slightly higher for CANA 100 and 300 mg than for PBO (77.8% and 74.2% vs 73.3%); serious AE rates were 11.1%, 11.2%, and 17.8%, respectively. AE-related discontinuation rates were low across groups. Incidences of superficial genital fungal infections were higher with CANA 100 and 300 mg than PBO (women, 6.3% and 4.9% vs 0%; men, 1.7% and 2.1% vs 0%). CANA 300 mg showed slightly higher urinary tract infection rates (7.9%) than other groups (5.6% for CANA 100 mg and PBO); no increases in upper tract infections were seen with CANA. Incidences of osmotic diuresis- and volume-related AEs were higher with CANA than with PBO ( $< 5\%$  per specific AE except hypotension [6.7%] and dizziness [5.6%] for CANA 300 mg). More subjects had  $\geq 1$  hypoglycaemia episode with CANA 100 and 300 mg than PBO (52.9% and 51.2% vs 36.4%). CANA 100 and 300 mg showed increases in serum creatinine (9% and 10% vs 4%) and blood urea nitrogen (9% and 6% vs 2%) compared with PBO. Changes in eGFR for CANA and PBO were approximately -10% (both doses) and -3%, respectively. Median ACR was reduced with CANA 100 and 300 mg compared with PBO (-21.6% and -12.4% vs -2.5%).

**Conclusion:** CANA was well tolerated and demonstrated efficacy in improving glycaemic control and reducing body weight in subjects with T2DM who had moderate renal impairment.

### Canagliflozin, a sodium glucose co-transporter 2 inhibitor, improves glycaemic control in subjects with type 2 diabetes inadequately controlled with diet and exercise

K. Stenlöf<sup>1</sup>, W.T. Cefalu<sup>2,3</sup>, C. Tong<sup>4</sup>, J. Yee<sup>4</sup>, S. Sha<sup>4</sup>, M. Alba<sup>4</sup>, W. Canovatchel<sup>4</sup>, G. Meininger<sup>4</sup>;<sup>1</sup>Clinical Trial Center, Sahlgrenska University Hospital, Gothenburg, Sweden,<sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, USA, <sup>3</sup>LSUHSC School of Medicine, New Orleans, USA, <sup>4</sup>Janssen Research & Development, L.L.C., Raritan, USA.

**Background and aims:** Canagliflozin (CANA) is a novel inhibitor of the sodium glucose co-transporter 2 in development for treating patients with type 2 diabetes mellitus (T2DM). This study evaluated the efficacy and safety of CANA monotherapy in subjects with T2DM inadequately controlled with diet and exercise.

**Materials and methods:** In this randomised, double-blind, placebo (PBO)-controlled, Phase 3 study, subjects with T2DM (N = 584) received CANA 100 or 300 mg or PBO once daily. Changes from baseline in glycaemic and other efficacy parameters were assessed at 26 weeks. Adverse events (AEs) were recorded throughout the study.

**Results:** Mean baseline characteristics were similar across groups (age, 55.4 years; HbA<sub>1c</sub>, 8.0%; body weight, 86.8 kg; body mass index, 31.6 kg/m<sup>2</sup>); 48.1% of subjects were on background anti-hyperglycaemic agents. As shown in the Table, mean HbA<sub>1c</sub> was substantively and statistically significantly reduced from baseline at 26 weeks with CANA 100 and 300 mg compared with PBO ( $P < 0.001$  for both). Both CANA doses showed statistically significant improvements in fasting plasma glucose (FPG) and 2-hour postprandial glucose (PPG) compared with PBO ( $P < 0.001$  for all). More PBO-treated subjects received rescue therapy (22.9%) than those treated with CANA 100 or 300 mg (2.6% and 2.0%, respectively). In addition, both CANA doses significantly reduced body weight, decreased systolic blood pressure (BP), and increased high-density lipoprotein cholesterol (HDL-C) compared with PBO ( $P < 0.001$  for all), with a small dose-related increase in low-density lipoprotein cholesterol (LDL-C). Overall incidences of AEs were modestly higher with CANA 100 and 300 mg (60.5% and 59.9%, respectively) compared with PBO (49.0%). Rates of serious AEs (CANA 100 mg, 4.1%; CANA 300 mg, 1.0%; PBO, 2.1%) and AE-related discontinuations (CANA 100 mg, 3.1%; CANA 300 mg, 2.0%; PBO, 1.0%) were low across groups. Incidences of AEs consistent with superficial genital fungal infections were higher with CANA in women (CANA 100 mg, 12.3%; CANA 300 mg, 12.0%; PBO, 3.8%) and men (CANA 100 mg, 2.5%; CANA 300 mg, 5.6%; PBO, 0%). A slightly higher incidence of urinary tract infections was seen with CANA (CANA 100 mg, 7.2%; CANA 300 mg, 5.1%; PBO, 4.2%), as well as osmotic diuresis-related AEs (eg, polyuria;  $< 3\%$  per specific AE); these were generally mild and led to few discontinuations. No pyelonephritis AEs were reported in any group. Incidences of hypoglycaemia were similar across groups (CANA 100 mg, 3.1%; CANA 300 mg, 3.0%; PBO, 2.6%).

**Conclusion:** Treatment with CANA 100 and 300 mg significantly improved glycaemic control and reduced body weight, and was well tolerated in subjects with T2DM inadequately controlled with diet and exercise.

**Table. Summary of Efficacy Endpoints at Week 26 (LOCF)**

**Canagliflozin, a sodium glucose co-transporter 2 (SGLT2) inhibitor, improves indices of beta cell function in patients with type 2 diabetes on metformin plus sulphonylurea**

D. Polidori<sup>1</sup>, F. Vercruysse<sup>2</sup>, E. Ferrannini<sup>3</sup>;

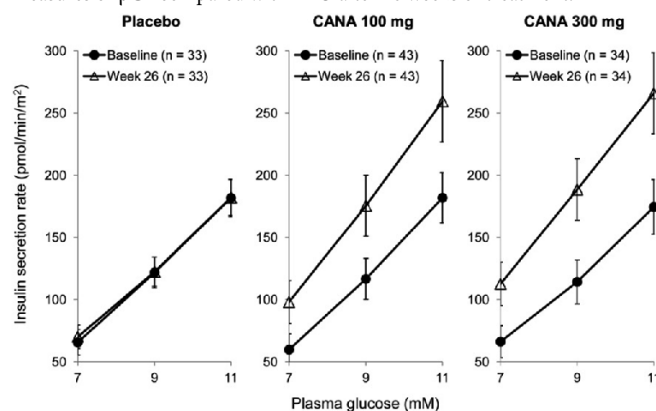

<sup>1</sup>Janssen Research & Development, L.L.C., San Diego, USA, <sup>2</sup>Janssen Research & Development, Beerse, Belgium, <sup>3</sup>University of Pisa School of Medicine, Italy.

**Background and aims:** Progressive loss of  $\beta$ -cell function ( $\beta$ CF) is thought to underlie the pathophysiology of type 2 diabetes mellitus (T2DM). Canagliflozin (CANA), an inhibitor of SGLT2, is in development for the treatment of T2DM. In hyperglycaemic, partially pancreatectomised rats,  $\beta$ CF can be restored when normoglycaemia is achieved with SGLT2 inhibitor treatment. In a Phase 3 study, 26 weeks of CANA monotherapy treatment improved glycaemic control and indices of  $\beta$ CF in patients with T2DM inadequately controlled with diet and exercise. To further assess the effects of CANA on  $\beta$ CF, indices of  $\beta$ CF were evaluated in a Phase 3 study of patients with T2DM inadequately controlled with metformin (MET) + sulphonylurea (SU).

**Materials and methods:** This 26-week, randomised, double-blind, placebo (PBO)-controlled study evaluated CANA 100 and 300 mg compared with PBO as add-on therapy to MET + SU in patients with T2DM (N = 469; mean baseline characteristics: age = 57 years; HbA<sub>1c</sub> = 8.1%; BMI = 33.0 kg/m<sup>2</sup>; duration of T2DM = 9.6 years). A subset of patients (n = 168) were given a meal tolerance test at baseline and Week 26 and plasma glucose (G) and serum C-peptide (C) were measured at 7 time points over 3 hours.  $\beta$ CF was assessed using the AUC<sub>C</sub>/AUC<sub>G</sub> ratio and a model-based method relating the insulin secretion rate (ISR; obtained by deconvolution of C) to concomitant G using linear regression.  $\beta$ -cell glucose sensitivity as the slope of ISR vs G relationship and ISR at 9 mM G were calculated. All changes are reported as PBO-subtracted least squares (LS) mean changes using an ANCOVA model.

**Results:** At Week 26, CANA 100 and 300 mg significantly reduced HbA<sub>1c</sub> from baseline compared with PBO ( $\Delta$ HbA<sub>1c</sub> = -0.71% and -0.92%, respectively;  $P < 0.001$ ) and were generally well tolerated. The ISR vs G relationship was unchanged with PBO and was shifted upwards (indicating increased ISR at each PG concentration) with both CANA doses (Figure). Mean values of all calculated indices of  $\beta$ CF increased with both CANA doses versus PBO, although some of the changes did not reach statistical significance. Mean AUC<sub>C</sub>/AUC<sub>G</sub> increased by ~20% from baseline values of 123–132 pM/mM (increases of 27.1 (95% CI = -0.2; 54.4;  $P = 0.051$ ) and 27.4 (-0.7; 55.6;  $P = 0.056$ ) for CANA 100 and 300 mg). Mean ISR at 9 mM G increased by ~50–60% from baseline values of 114–117 pmol/min/m<sup>2</sup> (increases of 54.6 (7.7; 101.5;  $P = 0.02$ ) and 69.2 (19.7; 118.9;  $P = 0.007$ ) for CANA 100 and 300 mg). Mean  $\beta$ -cell glucose sensitivity increased by ~20% from baseline values of 31–34 pmol·min<sup>-1</sup>·m<sup>-2</sup>·mM<sup>-1</sup> (increases of 7.6 (-2.6; 17.9;  $P = 0.14$ ) and 6.7 (-4.1; 17.5;  $P = 0.22$ ) for CANA 100 and 300 mg).

**Conclusion:** In T2DM patients (mean T2DM duration of 9.6 years) on background MET + SU, CANA 100 and 300 mg improved glycaemic control and measures of  $\beta$ CF compared with PBO after 26 weeks of treatment.

Values shown are mean  $\pm$  SEM for subjects studied at both baseline and Week 26

**Canagliflozin, a sodium glucose co-transporter 2 inhibitor, reduces body weight mainly through loss of fat mass in subjects with type 2 diabetes**

S. Toubro<sup>1</sup>, W.T. Cefalu<sup>2,3</sup>, J. Xie<sup>4</sup>, D. Sullivan<sup>4</sup>, K. Usiskin<sup>4</sup>, W. Canovatchel<sup>4</sup>, G. Meininger<sup>4</sup>;

<sup>1</sup>Reduce, A Research Clinic, Vipperød, Denmark, <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, USA, <sup>3</sup>LSUHSC School of Medicine, New Orleans, USA, <sup>4</sup>Janssen Research & Development, L.L.C., Raritan, USA.

**Background and aims:** Canagliflozin (CANA) is a sodium glucose co-transporter 2 inhibitor that improves the glycaemic profile and reduces body weight in type 2 diabetes mellitus (T2DM) subjects. Body composition analysis was conducted to determine the relative contributions of weight loss from fat and lean mass in a subset of subjects with T2DM enrolled in 2 randomised, double-blind, Phase 3 studies.

**Materials and methods:** Study 1 was an active-controlled trial comparing CANA 100 and 300 mg with glimepiride (GLIM) in T2DM subjects inadequately controlled on metformin (N = 1,450; mean baseline characteristics: age, 56.2 years; HbA<sub>1c</sub>, 7.8%; body weight, 86.6 kg). Study 2 was a placebo (PBO)-controlled trial that evaluated CANA 100 and 300 mg in subjects aged 55 to 80 years (N = 714) with T2DM on a variety of background anti-hyperglycaemic agents (AHAs); mean baseline characteristics were similar across groups (age, 63.6 years; HbA<sub>1c</sub>, 7.7%; body weight, 89.5 kg). Body composition was assessed in a subset of subjects by dual-energy X-ray absorptiometry (DXA) at 52 weeks in Study 1 (n = 208) and at 26 weeks in Study 2 (n = 211). Abdominal fat distribution was also assessed by computed tomography (CT) scans at 52 weeks in Study 1 only (n = 217).

**Results:** In T2DM subjects on background metformin (Study 1 [Table]), CANA 100 and 300 mg significantly reduced body weight compared with GLIM ( $P < 0.001$  for both) at 52 weeks (least squares [LS] mean changes from baseline of -4.2, -4.7, and 1.0 kg, respectively). Loss of fat mass accounted for approximately two-thirds of the overall body weight reduction seen with CANA. Both CANA doses also showed reductions in percent total fat (fat percentage of the total weight) compared with GLIM. Similar results were observed in Study 2 subjects on a variety of background AHAs (Table). CANA 100 and 300 mg significantly reduced body weight compared with PBO ( $P < 0.001$  for both) after 26 weeks of treatment (LS mean changes from baseline of -2.5, -3.3, and -0.2 kg, respectively). Greater loss from fat mass than from lean mass was observed for CANA 100 and 300 mg, and both CANA doses showed reductions compared with PBO in percent total fat. Analysis of abdominal fat in Study 1 showed slightly greater changes in the amount of visceral adipose tissue (LS mean changes relative to GLIM of -7.4% and -8.3%, respectively) than changes in subcutaneous adipose tissue (LS mean changes relative to GLIM of -7.2% and -7.4%, respectively) with CANA 100 and 300 mg.

**Conclusion:** The body weight reductions seen in subjects with T2DM following 26 or 52 weeks of treatment with CANA 100 or 300 mg were predominantly (>2/3) from fat mass. There was a numerically greater percentage loss of visceral relative to subcutaneous fat in the abdomen.

Table. Summary of Body Composition Endpoints

Study 1, Week 52 (LOCF)			
Parameter <sup>a</sup>	CANA 100 mg (N = 71)	CANA 300 mg (N = 69)	GLIM (N = 68)
Body weight % change	-5.0 (0.7)	-4.9 (0.7)	1.4 (0.8)
Difference vs GLIM	-6.4 (-7.5, -5.2)	-6.2 (-7.4, -5.1)	
DXA			
Total fat measurement change, kg	-2.9 (0.5)	-2.5 (0.5)	1.0 (0.5)
Difference vs GLIM	-3.9 (-4.8, -3.1)	-3.5 (-4.4, -2.6)	
Total lean measurement change, kg	-0.9 (0.3)	-1.1 (0.3)	1.1 (0.3)
Difference vs GLIM	-1.9 (-2.5, -1.3)	-2.2 (-2.8, -1.6)	
Percent total fat change, % <sup>b</sup>	-2.0 (0.4)	-1.5 (0.5)	0.7 (0.4)
Difference vs GLIM	-2.6 (-3.3, -1.9)	-2.2 (-3.0, -1.4)	
Study 2, Week 26 (LOCF)			
Parameter <sup>a</sup>	CANA 100 mg (N = 63)	CANA 300 mg (N = 73)	PBO (N = 75)
Body weight % change	-2.5 (0.4)	-3.3 (0.4)	-0.2 (0.4)
Difference vs PBO	-2.3 (-3.3, -1.4)	-3.1 (-4.0, -2.2)	
DXA			
Total fat measurement change, kg	-1.8 (0.3)	-2.5 (0.3)	-0.3 (0.3)
Difference vs PBO	-1.5 (-2.3, -0.7)	-2.2 (-2.9, -1.4)	
Total lean measurement change, kg	-1.1 (0.3)	-1.1 (0.3)	-0.3 (0.3)
Difference vs PBO	-0.7 (-1.4, -0.1)	-0.8 (-1.4, -0.2)	
Percent total fat change, % <sup>b</sup>	-0.9 (0.3)	-1.3 (0.3)	-0.02 (0.3)
Difference vs PBO	-0.9 (-1.5, -0.3)	-1.3 (-1.9, -0.7)	

LOCF, last observation carried forward; SE, standard error; ANCOVA, analysis of covariance; CI, confidence interval. <sup>a</sup>Least squares mean (SE) change from baseline using ANCOVA and difference (95% CI) vs GLIM (Study 1) or PBO (Study 2). <sup>b</sup>Percent total fat (%) = Total fat measurement (kg)/(Total fat measurement [kg] + Total lean measurement [kg] + bone mineral content [kg]).

### Efficacy and safety of canagliflozin, a sodium glucose co-transporter 2 inhibitor, compared with glimepiride in patients with type 2 diabetes on background metformin

L. Niskanen<sup>1,2</sup>, W.T. Cefalu<sup>3,4</sup>, L.A. Leiter<sup>5</sup>, J. Xie<sup>6</sup>, D. Balis<sup>6</sup>, W. Canovatchel<sup>6</sup>, G. Meininger<sup>6</sup>

<sup>1</sup>Central Hospital Central Finland, Jyväskylä, Finland, <sup>2</sup>University of Eastern Finland, Kuopio, Finland, <sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, USA, <sup>4</sup>LSUHSC School of Medicine, New Orleans, USA, <sup>5</sup>St. Michael's Hospital and University of Toronto, Canada, <sup>6</sup>Janssen Research & Development, L.L.C., Raritan, USA.

**Background and aims:** This 52-week study evaluated the efficacy and safety of canagliflozin (CANA), a sodium glucose co-transporter 2 inhibitor, compared with glimepiride (GLIM) in subjects with type 2 diabetes mellitus (T2DM) inadequately controlled with metformin (MET).

**Materials and methods:** In this large, randomised, double-blind, active-controlled, Phase 3 study (N = 1,450), subjects with T2DM inadequately controlled with MET received CANA 100 or 300 mg or GLIM (doses titrated over 52 weeks up to 6 or 8 mg/day, with mean dose achieved of 5.6 mg). Changes from baseline in efficacy endpoints were assessed at Week 52. Adverse events (AEs) were recorded throughout the study.

**Results:** Mean baseline characteristics were similar across groups (age, 56.2 years; HbA<sub>1c</sub>, 7.8%; body weight, 86.6 kg; body mass index, 31.0 kg/m<sup>2</sup>). As shown in the Figure, HbA<sub>1c</sub> (primary endpoint) was reduced from baseline at 52 weeks with CANA 100 and 300 mg and GLIM (least squares [LS] mean changes of -0.82%, -0.93%, and -0.81%). Both CANA doses demonstrated non-inferiority to GLIM in reducing HbA<sub>1c</sub>, and CANA 300 mg demonstrated superiority to GLIM. CANA 100 and 300 mg provided consistently lower HbA<sub>1c</sub> over 52 weeks while GLIM showed increases in HbA<sub>1c</sub> after Week 18. CANA 100 and 300 mg were superior to GLIM (*P* < 0.001 for all) in body weight reduction (LS mean changes of -4.2, -4.7, and 1.0 kg) and documented hypoglycaemia (defined as ≤3.9 mmol/L) rates (5.6%, 4.9%, and 34.2%). Both CANA doses showed improvements in fasting plasma glucose (FPG), systolic blood pressure (BP), triglycerides, and high-density lipoprotein cholesterol (HDL-C); there was a small dose-related increase in low-density lipoprotein cholesterol (LDL-C) with CANA. More GLIM-treated subjects received rescue therapy (10.6%) than with CANA 100 mg (6.6%) or 300 mg (4.9%).

The overall incidence of AEs was similar with CANA 100 mg (64.2%), CANA 300 mg (68.5%), and GLIM (67.6%). Rates of serious AEs (CANA 100 mg, 5.0%; CANA 300 mg, 4.9%; GLIM, 7.9%) and AE-related discontinuations (CANA 100 mg, 5.2%; CANA 300 mg, 6.8%; GLIM, 5.8%) were low and similar across groups. AEs consistent with superficial genital fungal infections were more frequent with CANA 100 and 300 mg than with GLIM in women (14.3% and 23.8% vs 3.7%) and men (6.7% and 8.3% vs 1.1%). CANA showed slightly higher rates relative to GLIM of urinary tract infections (6.4% for both doses vs 4.4%) and osmotic diuresis-related AEs (eg, pollakiuria; <3% for each specific AE).

**Conclusion:** CANA showed consistent HbA<sub>1c</sub> lowering over 52 weeks and reduced body weight compared with GLIM, and was well tolerated in subjects with T2DM inadequately controlled with MET.

### Efficacy and safety of canagliflozin (CANA), an inhibitor of sodium glucose co-transporter 2 (SGLT2), added-on to insulin therapy +/- oral agents in type 2 diabetes

D.R. Matthews<sup>1</sup>, G. Fulcher<sup>2</sup>, V. Perkovic<sup>3</sup>, D. de Zeeuw<sup>4</sup>, K.W. Mahaffey<sup>5</sup>, J. Rosenstock<sup>6</sup>, M. Davies<sup>7</sup>, G. Capuano<sup>8</sup>, M. Desai<sup>8</sup>, W. Shaw<sup>8</sup>, F. Vercruysee<sup>8</sup>, G. Meininger<sup>8</sup>, B. Neal<sup>3</sup>

<sup>1</sup>The Churchill Hospital, Oxford, UK, <sup>2</sup>Royal North Shore Hospital, Sydney, Australia, <sup>3</sup>George Inst for Global Health, Sydney, Australia, University Med Ctr Groningen, Netherlands, <sup>4</sup>Duke Clin Res Inst, Durham, USA, <sup>5</sup>Dallas Diab & Endo Ctr, Dallas, USA, University of Leicester, UK, <sup>8</sup>Janssen R&D, L.L.C., Raritan, USA.

**Background and aims:** Inhibition of SGLT2 is a novel modality of treatment for patients with T2D. We report here a pre-specified substudy of the canagliflozin Cardiovascular Assessment Study (CANVAS) defining the efficacy, safety and tolerability of CANA in participants with T2D on insulin.

**Materials and methods:** CANVAS is a double-blind, placebo (PBO)-controlled study that randomised 4,330 individuals at elevated cardiovascular risk to the addition of PBO, CANA 100 or 300 mg, once daily, to stable ongoing diabetes therapy. In the subgroup using insulin (≥30 units/d), there were 565, 566 and 587 individuals, respectively. The primary endpoint for this sub-study was the change from baseline in HbA<sub>1c</sub> at 18 weeks follow-up while the insulin doses were kept unchanged as per protocol. Major vascular outcomes remained blinded.

**Results:** Baseline demographics demonstrated no imbalances; 67% of participants were male and 59% had a history of a prior vascular event. Mean baseline age was 63 y, HbA<sub>1c</sub> 8.3%, BMI 33.8 kg/m<sup>2</sup>, body weight 97.0 kg, fasting plasma glucose 9.4 mmol/L, total cholesterol 4.3 mmol/L and blood pressure 138/76 mmHg. Mean daily insulin dose at baseline was 83 IU with most using basal/bolus insulin regimens and a median duration of diabetes of 15 y. Compared to PBO both doses of CANA significantly improved measures of glycaemia (Table). Adverse events (AEs) were reported for the CANA 100 mg, CANA 300 mg and PBO groups in 63%, 65% and 59% of participants and serious AEs in 5.5%, 4.9% and 6.4% respectively. Incidence of AEs leading to discontinuation was greater with CANA 300 mg (5.3%) compared to CANA 100 mg or PBO (both 1.9%). Male and female genital fungal infections were more common with CANA 100 mg (F:11.8%, M:4.0%) and 300 mg (F:9.9%, M:8.3%) compared to PBO (F:2.2%, M:0.5%) as were AEs of pollakiuria and hypotension with CANA 100 mg (3.7% and 1.2%, respectively) and CANA 300 mg (5.6% and 2.6%, respectively), compared to PBO (0.5% and 0%, respectively). A slightly higher incidence of UTI was seen with CANA 300 mg (3.4%) relative to CANA 100 mg and PBO (2.3% and 2.1%, respectively). In-

cidence of hypoglycaemia was higher with CANA 100 mg (49%) and CANA 300 mg (48%) than PBO (37%).

**Conclusion:** CANA added to stable insulin therapy improved glycaemic control and produced significant improvements in a number of efficacy parameters important in the management of T2D with effects of the 300 mg dose numerically greater than the 100 mg dose. CANA was generally well tolerated, and associated with a greater frequency of genital fungal infections and slightly higher risk of hypoglycaemia.

Table. Effects on primary and secondary outcomes\*

	Difference CANA 100 mg vs. placebo	Difference CANA 300 mg vs. placebo

### Efficacy and safety of canagliflozin (CANA), a sodium glucose co-transporter 2 inhibitor (SGLT2), in older subjects with type 2 diabetes mellitus

B. Bode<sup>1</sup>, K. Stenlöf<sup>2</sup>, D. Sullivan<sup>3</sup>, A. Fung<sup>3</sup>, K. Usiskin<sup>3</sup>, G. Meininger<sup>3</sup>;

<sup>1</sup>Atlanta Diabetes Associates, Atlanta, USA, <sup>2</sup>Clinical Trial Center,

Sahlgrenska University Hospital, Gothenburg, Sweden, <sup>3</sup>Janssen Research & Development, L.L.C., Raritan, USA.

**Background and aims:** The efficacy and safety of CANA, an inhibitor of the SGLT2, were evaluated in this randomised, double-blind, placebo (PBO)-controlled, Phase 3 study in older subjects with T2DM inadequately controlled with anti-hyperglycaemic agents (AHAs).

**Materials and methods:** Subjects aged 55 to 80 years with T2DM (N = 714) inadequately controlled with a stable AHA regimen received CANA 100 or 300 mg or PBO daily. Efficacy endpoints were evaluated at 26 weeks and safety was assessed by adverse event (AE) reports. Changes in bone biomarkers and bone density (measured by DXA at 4 sites: lumbar spine, total hip, femoral neck, distal forearm) were also determined.

**Results:** Mean baseline characteristics were similar across groups (age, 63.6 years; HbA<sub>1c</sub>, 7.7%; body weight, 89.5 kg). Background AHAs included metformin (85.3%), sulphonylureas (48.7%), and insulin (32.7%), with 76% of subjects on ≥2 classes of AHAs at baseline. As shown in the Table, CANA 100 and 300 mg showed significant reductions in HbA<sub>1c</sub> and improvements in fasting plasma glucose at Week 26 compared with PBO (P <0.001 for all). Both CANA doses significantly reduced body weight and improved systolic blood pressure (BP) and high-density lipoprotein cholesterol (HDL-C) (P <0.001 for all), with small increases observed in low-density lipoprotein cholesterol (LDL-C) compared with PBO.

Table. Summary of Efficacy Endpoints at Week 26 (LOCF)

Parameter, mean (SE) <sup>a,b</sup>	CANA 100 mg (N = 241)	CANA 300 mg (N = 236)	PBO (N = 237)
HbA <sub>1c</sub> change, %	-0.60 (0.06)	-0.73 (0.06)	-0.03 (0.06)
Difference vs PBO	-0.57 (0.07) <sup>c</sup>	-0.70 (0.07) <sup>c</sup>	
FPG change, mmol/L	-1.0 (0.2)	-1.1 (0.2)	0.4 (0.2)
Difference vs PBO	-1.4 (0.2) <sup>c</sup>	-1.5 (0.2) <sup>c</sup>	
Body weight % change	-2.4 (0.3)	-3.1 (0.3)	-0.1 (0.3)
Difference vs PBO	-2.3 (0.3) <sup>c</sup>	-3.0 (0.3) <sup>c</sup>	
Systolic BP change, mmHg	-3.5 (1.0)	-6.8 (1.1)	1.1 (1.0)
Difference vs PBO	-4.6 (1.1) <sup>c</sup>	-7.9 (1.1) <sup>c</sup>	
Diastolic BP change, mmHg	-1.6 (0.6)	-3.2 (0.6)	0.1 (0.6)
Difference vs PBO	-1.6 (0.6)	-3.2 (0.7)	
Triglycerides % change	2.8 (3.3)	8.4 (3.4)	7.6 (3.4)
Difference vs PBO	-4.8 (3.7) <sup>d</sup>	0.7 (3.7) <sup>d</sup>	
LDL-C % change	14.2 (3.2)	14.5 (3.3)	6.7 (3.3)
Difference vs PBO	7.5 (3.6)	7.8 (3.6)	
HDL-C % change	6.8 (1.2)	6.2 (1.2)	1.5 (1.2)
Difference vs PBO	5.3 (1.4) <sup>c</sup>	4.7 (1.4) <sup>c</sup>	
LDL-C/HDL-C % change	8.7 (3.4)	11.5 (3.4)	5.6 (3.5)
Difference vs PBO	3.1 (3.8)	5.9 (3.8)	

LOCF, last observation carried forward; SE, standard error; ANCOVA, analysis of covariance; NS, not significant. <sup>a</sup>Least squares mean (SE) change from baseline using ANCOVA; <sup>b</sup>P values are reported for pre-specified comparisons only; <sup>c</sup>P <0.001 vs PBO; <sup>d</sup>P = NS vs PBO.

The overall incidence of AEs was similar with CANA 100 and 300 mg and PBO (71.8% and 78.0% vs 73.4%). Rates of serious AEs (4.1% and 3.4% vs 5.1%) and AE-related discontinuations (2.1% and 7.2% vs 4.2%) were low across groups. CANA 100 and 300 mg showed higher rates than PBO of superficial genital fungal infections (women, 18.8% and 17.8% vs 4.3%; men, 3.2% and 6.2% vs 0%), urinary tract infections (5.8% and 8.1% vs 5.1%), and osmotic diuresis-related AEs (<6% per specific AE). Hypoglycaemia (≤3.9 mmol/L) rates were modestly higher with CANA 100 and 300 mg than PBO in subjects on an AHA associated with hypoglycaemia (43.1% and 47.4% vs 37.7%) as well as those on AHAs not associated with hypoglycaemia (6.7% and 4.8% vs 3.2%). CANA 100 and 300 mg showed small increases (16.2% and 23.9% [PBO-subtracted]) in serum collagen type 1 beta-carboxy telopeptide (beta-CTX), a bone resorption marker, and small decreases (-5.5% and -6.8% [PBO-subtracted]) in serum propeptide amino-term type 1 procollagen (PINP), a bone formation marker. There were no discernable changes in bone density seen at the spine, hip, or distal forearm.

**Conclusion:** CANA 100 and 300 mg improved glycaemic control, reduced body weight and systolic BP, and was well tolerated in older subjects with T2DM inadequately controlled with a variety of background AHAs, with no discernable changes in cortical or trabecular bone density.

### Canagliflozin, a sodium glucose co-transporter 2 inhibitor, improves glycaemia in subjects with type 2 diabetes inadequately controlled with metformin plus sulphonylurea

J. Wilding<sup>1</sup>, C. Mathieu<sup>2</sup>, L. Deng<sup>3</sup>, S. Black<sup>3</sup>, F. Vercruysse<sup>4</sup>, W. Canovatchel<sup>3</sup>, G. Meininger<sup>3</sup>;

<sup>1</sup>University of Liverpool, Liverpool, UK, <sup>2</sup>KULeuven, Belgium, <sup>3</sup>Janssen

Research & Development, L.L.C., Raritan, USA, <sup>4</sup>Janssen Research & Development, Beerse, Belgium.

**Background and aims:** Canagliflozin (CANA), a sodium glucose co-transporter 2 inhibitor, is in development as a novel treatment for patients with type 2 diabetes mellitus (T2DM). This study assessed the efficacy and safety of CANA in subjects with T2DM who have inadequate glycaemic control with metformin (MET) plus sulphonylurea (SU) therapy.

**Materials and methods:** In this randomised, double-blind, placebo (PBO)-controlled, Phase 3 study, subjects with T2DM on MET + SU (N = 469) received daily treatment with CANA 100 mg or 300 mg or PBO. Changes from baseline in glycaemic and other efficacy parameters were evaluated at Week 26. Adverse events (AEs) were recorded throughout the study.

**Results:** Mean baseline characteristics were similar across groups (age, 56.7 years; HbA<sub>1c</sub>, 8.1%; body weight, 92.8 kg; body mass index, 33.0 kg/m<sup>2</sup>). As shown in the Table, HbA<sub>1c</sub> was significantly reduced from baseline at 26 weeks with CANA 100 and 300 mg compared with PBO (P <0.001 for both). Both CANA doses significantly improved fasting plasma glucose (FPG) compared with PBO (P <0.001 for both). More PBO-treated subjects received rescue therapy (12.8%) than those treated with CANA 100 or 300 mg (1.3% and 1.9%, respectively). Both CANA doses significantly reduced body weight compared with PBO (P <0.001 for both) and showed non-dose-dependent trends toward improvement in systolic blood pressure (BP), high-density lipoprotein cholesterol (HDL-C), and triglycerides (not statistically significant); there was a small increase seen in low-density lipoprotein cholesterol (LDL-C) with CANA 300 mg compared with PBO. Overall, the incidence of AEs was similar across groups (CANA 100 mg, 57.3%; CANA 300 mg, 62.2%; PBO, 63.5%). Rates of serious AEs (CANA 100 mg, 3.2%; CANA 300 mg, 3.8%; PBO, 5.8%) and AE-related discontinuations (CANA 100 mg, 5.7%; CANA 300 mg, 5.8%; PBO, 3.2%) were low. CANA showed higher rates of AEs consistent with superficial genital fungal infections in women (CANA 100 mg, 16.0%; CANA 300 mg, 21.7%; PBO, 5.0%) and men (CANA 100 mg, 6.6%; CANA 300 mg, 3.4%; PBO, 1.3%). Incidences of osmotic diuresis-related AEs were low, although numerically higher with CANA (<3% per specific AE), but none led to study discontinuation. Rates of urinary tract infections were similar among groups (CANA 100 mg, 6.4%; CANA 300 mg, 5.8%; PBO, 5.1%). More subjects treated with CANA had ≥1 hypoglycaemia episode (CANA 100 mg, 26.8%; CANA 300 mg, 30.1%; PBO, 15.4%), but the number of severe hypoglycaemia episodes was low (≤1 per group) and similar across groups.

**Conclusion:** Treatment with CANA 100 and 300 mg provided glycaemic improvement, reduced body weight, and was well tolerated in subjects with T2DM inadequately controlled with MET + SU.

**Tofogliflozin a selective SGLT2 inhibitor exhibits highly favourable drug properties for use in patients with renal impairment and for combination with other medicines**

D. Schwab<sup>1</sup>, A. Portron<sup>1</sup>, Y. Fukushima<sup>1</sup>, Z. Backholer<sup>1</sup>, O. Kuhlmann<sup>1</sup>, T. Saito<sup>2</sup>, S. Ikeda<sup>2</sup>, Hoffmann-La Roche AG, Basel, Switzerland, <sup>2</sup>Chugai Pharmaceutical Co., Ltd, Tokyo, Japan.

**Background and aims:** Tofogliflozin (TOFO) is a novel selective SGLT2 inhibitor increasing glucosuria by inhibition of glucose reabsorption in the kidney for the treatment of type 2 diabetes mellitus (T2DM). Patients with T2DM exhibit various degrees of renal impairment and take a variety of co-medications. Therefore, we investigated the suitability of TOFO to be administered to patients with impaired renal function as well as the potential of the drug-drug interactions of TOFO and common co-medications.

**Materials and methods:** TOFO was characterized in several clinical pharmacology studies following single dose administration: 1) concomitant oral and intravenous microdose administration as part of an ADME investigation in healthy subjects, 2) drug-drug interaction study in healthy subjects, 3) in patients with T2DM with varying degree of renal function. In vitro data was obtained in human liver microsomes.

**Results:** Renal clearance of TOFO accounts for 19% of total systemic clearance. A study in 36 T2DM patients with varying degree of renal function (eGFR from 8 to >90 mL/min) demonstrated that impaired renal function does not affect systemic exposure of TOFO significantly (figure). Although lower urinary glucose excretion correlated with lower eGFR, the inhibition of renal glucose reabsorption was constant across all renal function groups. This indicates that TOFO reached its target in the kidney independent on renal function. Several preclinical and clinical studies support TOFO's low risk for drug-drug interactions with concomitant use of medications in respect to both TOFO as a victim and as a perpetrator of drug-drug interactions. In vitro data shows lack of a relevant interference of TOFO with CYP enzymes and drug transporters suggesting that TOFO is unlikely to cause a relevant change in exposures of co-medications. The susceptibility of TOFO to become a victim of a drug-drug interaction was assessed by combining in vitro data and clinical data from a mass balance study. TOFO is eliminated via multiple elimination pathways, suggesting minor susceptibility for drug-drug interactions. Moreover, the main metabolic pathway is predominantly driven by alcohol dehydrogenase and additional enzymes. The multiplicity of enzymes involved in the main metabolic pathway, and supportive clinical data suggest a low potential for drug-drug interactions.

**Conclusion:** TOFO exhibits highly favorable clinical and in vitro drug properties for the use in the target population that is subject to a variety of co-medications and which presents with various degrees of renal function.

**Figure:** Relationship between oral clearance (CL/F) of TOFO and estimated glomerular filtration rate (eGFR)

**A novel and selective SGLT2 inhibitor, tofogliflozin improves glycaemic control and lowers body weight in patients with type 2 diabetes mellitus**  
S. Ikeda<sup>1</sup>, Y. Takano<sup>1</sup>, O. Cynshi<sup>1</sup>, A.D. Christ<sup>2</sup>, V. Boerlin<sup>2</sup>, U. Beyer<sup>2</sup>, A. Beck<sup>2</sup>, <sup>1</sup>Chugai Pharmaceutical Co., Ltd, Tokyo, Japan, <sup>2</sup>F. Hoffmann-La Roche AG, Basel, Switzerland.

**Background and aims:** Sodium-glucose cotransporter 2 (SGLT2) inhibitor is expected to be an emerging oral antidiabetic with insulin independent mode of action. Urinary glucose excretion (UGE) induced by selective inhibition of SGLT2 elicits a complex set of metabolic changes on top of blood glucose lowering and ameliorates type 2 diabetes mellitus (T2DM). Tofogliflozin is a novel and highly selective SGLT2 inhibitor.

**Materials and methods:** Safety, tolerability and efficacy of tofogliflozin was evaluated in a double-blind, randomized, placebo-controlled 12-week dose finding study. After 4-week placebo run-in period, total 398 T2DM patients were randomized to tofogliflozin 2.5, 5, 10, 20, 40 mg or placebo (qd, 15 min before breakfast). Treatment background in the study consisted of (1) treated with diet and exercise and a stable dose of metformin (approx.60% of total) or (2) treated with diet and exercise alone (remaining 40%).

**Results:** Significant (except for 2.5 mg) and dose-dependent reductions of HbA<sub>1c</sub> were shown with a maximum lowering of 0.56% (placebo-adjusted, at 40 mg), along with increased UGE. No clear difference was found between two treatment backgrounds. Dose-dependent fasting plasma glucose and body weight reduction were also observed (Table), glucose intolerance was improved and there was a trend for median blood pressure to decrease by 3-4 mmHg.

**Conclusion:** Once daily doses of tofogliflozin for 12 weeks were effective, well tolerated and no new clinical safety concerns were identified in addition to the known genital infections reported with other SGLT2 inhibitors in development.

### Empagliflozin, a novel sodium glucose cotransporter-2 inhibitor, improves glucose homeostasis and preserves pancreatic beta cell mass in db/db mice

J. Jelsing<sup>1</sup>, E. Mayoux<sup>2</sup>, T. Klein<sup>2</sup>, R. Grempler<sup>2</sup>, M. Mark<sup>2</sup>;

<sup>1</sup>Gubra ApS, Hørsholm, Denmark, <sup>2</sup>Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany.

**Background and aims:** Empagliflozin is a potent and selective sodium glucose cotransporter-2 (SGLT2) inhibitor (SGLT-2) in development for the treatment of type 2 diabetes mellitus. This study investigated the effect of 12 weeks' treatment with empagliflozin on glucose homeostasis and pancreatic beta cell function in db/db mice.

**Materials and methods:** Db/db mice were treated with vehicle (n=10), empagliflozin 3 mg/kg (n=8) or empagliflozin 10 mg/kg (n=8) per os once daily for 84 days. Body weight, fasting plasma glucose, HbA<sub>1c</sub> and fasting insulin were measured. Following sacrifice, pancreatic tissue was dissected and total beta cell mass (insulin immunoreactive cells) and non-beta cell mass (glucagon, pancreatic polypeptide and somatostatin immunoreactive cells) were assessed using stereology.

**Results:** Treatment with empagliflozin 3 mg/kg and 10 mg/kg prevented the decline in body weight normally seen in diabetic db/db mice associated with health deterioration (+8.68g and +7.67g, respectively, versus -4.01g with vehicle;  $p < 0.05$ ). Empagliflozin resulted in a marked reduction in fasted plasma glucose (408mg/dl and 348mg/dl with 3 mg/kg and 10 mg/kg empagliflozin, respectively, versus 843mg/dl with controls at day 84 of treatment;  $p < 0.05$ ). The improvement in glucose homeostasis was confirmed by a reduction in HbA<sub>1c</sub> that reached significance for the 10 mg/kg dose (5.87% versus 4.71% with vehicle,  $p < 0.05$ ). Fasting insulin tended to be higher with empagliflozin 10 mg/kg compared with vehicle (31 versus 20  $\mu$ U/ml). In addition, at days 8 and 70 of treatment, results from oral glucose tolerance tests showed an improvement in glucose disposal rate with both empagliflozin 3 mg/kg and 10 mg/kg versus vehicle. The total beta cell mass was significantly larger for the 10 mg/kg empagliflozin group compared with vehicle (4.24mg versus 2.46mg,  $p < 0.05$ ), with a similar tendency in the 3 mg/kg group (3.29mg) compared to vehicle (NS). The non-beta-cell mass was the same across all three groups.

**Conclusion:** The data demonstrate that empagliflozin, by eliminating glucose in urine, improves glucose homeostasis and delays disease progression in db/db mice coupled to an improvement in beta cell mass.

### The sodium glucose cotransporter-2 (SGLT-2) inhibitor empagliflozin lowers blood pressure independent of weight or HbA<sub>1c</sub> changes

T. Hach<sup>1</sup>, H.J. Lambers Heerspink<sup>2</sup>, E. Pfarr<sup>1</sup>, S. Lund<sup>1</sup>, L. Ley<sup>1</sup>, U.C. Broedl<sup>1</sup>, H.J. Woerle<sup>1</sup>;

<sup>1</sup>Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany,

<sup>2</sup>University Medical Center Groningen, University of Groningen, Netherlands.

**Background and aims:** Empagliflozin (EMPA) is a potent, selective sodium glucose cotransporter-2 inhibitor in development for treatment of type 2 diabetes mellitus (T2DM). Given evidence of effects of EMPA on glucose, weight and BP in Phase II trials, we analysed pooled patient data to evaluate the effects of EMPA on BP and the correlations between changes in weight or HbA<sub>1c</sub> and changes in BP.

**Materials and methods:** Two randomised, double-blind, parallel group, placebo (PBO)-controlled, dose-finding Phase 2b trials examined the safety and efficacy of EMPA as monotherapy (N=408) and as add-on to metformin (N=495) in patients with T2DM. Identical endpoints, study duration (12 weeks), and the sample size justified using the pooled dataset of the two EMPA doses tested in Phase 3 trials: EMPA 10 mg (N=152) and EMPA 25 mg (N=152) versus PBO (N=153). Changes from baseline in BP at 12 weeks were assessed and Pearson correlation coefficients were calculated. The frequency of any adverse events (AE) was calculated. Patients with a systolic BP (SBP) > 140 mmHg at baseline were analysed as a subgroup.

**Results:** Baseline mean ( $\pm$ SD) age, HbA<sub>1c</sub> and BMI of all patients in the Phase 2b trials were 57.9 $\pm$ 9.3 years, 7.9 $\pm$ 0.8% and 30.3 $\pm$ 4.7 kg/m<sup>2</sup>, respectively. Patients were predominantly white (83%), with an equal gender dis-

tribution and the majority (67%) were on anti-hypertensive medication at baseline. Baseline BP and changes from baseline in BP in patients on EMPA 10 mg, EMPA 25 mg and PBO are reported (Table). SBP decreased by 4-5 mmHg with EMPA; for each dose group, the change was significant versus placebo. The changes appeared to be larger in patients with SBP > 140 mmHg at baseline. DBP changes were more pronounced with EMPA, but did not reach statistical significance versus PBO. Changes in blood pressure did not correlate with changes in pulse rate. The Pearson correlation coefficients between change in weight and change in SBP were 0.10 (EMPA 10 mg), 0.04 (EMPA 25 mg) and 0.12 (PBO), and between change in HbA<sub>1c</sub> and change in SBP were -0.09 (EMPA 10 mg), -0.02 (EMPA 25 mg) and 0.11 (PBO). None of these correlations reached statistical significance ( $p > 0.14$ , for each). Including the number of antihypertensive medications at baseline in the ANCOVA model did not alter the PBO-adjusted effects on BP. The number of patients with AEs was comparable among treatment groups (34.2% in EMPA 10 mg, 31.6% in EMPA 25 mg, and 34.6% in PBO groups).

**Conclusion:** Treatment with EMPA was well tolerated and provided statistically significant and clinically meaningful reductions in SBP of 4-5 mmHg. Lowering of SBP with EMPA seemed more pronounced in patients with SBP > 140 mmHg at baseline. BP changes were not correlated with changes in weight or HbA<sub>1c</sub>, suggesting that EMPA has effects on BP related to its mode of action that are beyond its effects on weight and HbA<sub>1c</sub>.

### Effect of empagliflozin, on body weight, glucose control and plasma parameters in STZ induced diabetic rats fed a high-fat diet: comparison with exenatide

S.P. Vickers<sup>1</sup>, T. Klein<sup>2</sup>, R.B. Jones<sup>1</sup>, S.C. Cheetham<sup>1</sup>, E. Mayoux<sup>2</sup>, R. Grempler<sup>2</sup>, M. Mark<sup>2</sup>;

<sup>1</sup>RenaSci Ltd., Nottingham, UK, <sup>2</sup>Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany.

**Background and aims:** The effect of the sodium glucose cotransporter-2 inhibitor empagliflozin versus exenatide or vehicle on body weight, glucose control and relevant plasma parameters in animals fed a high fat diet and given low dose streptozotocin (STZ) to induce diabetes was determined.

**Materials and methods:** Male Sprague-Dawley rats (mean body weight approx. 430g) were administered vehicle or STZ (35 mg/kg ip) and maintained on a high fat diet (60% kcal as fat). After 1 week, these animals were allocated to one of 3 treatment groups (vehicle, empagliflozin, or exenatide; n=12 in all groups). After a 7-day baseline phase in which all animals received vehicle orally (po) once daily (qd), animals were dosed with vehicle (po) qd, empagliflozin (10 mg/kg po) qd or exenatide (30  $\mu$ g/kg/day) administered via subcutaneous osmotic pumps. Exenatide animals were also dosed with vehicle (po) qd. All other study animals were implanted with control pumps filled with saline. A non-STZ, vehicle-treated control group was also included (n=12). Body weight and food intake were monitored daily for 29 days. HbA<sub>1c</sub>, plasma glucose, insulin and triacylglycerol (TAG) were monitored. On Day 23, an OGTT (2 g/kg po) was performed after an overnight fast. Blood samples (4-hour fasted) were taken at termination (Day 29). Data were analysed by ANCOVA with multiple t tests for comparisons to control groups.

**Results:** At study end, STZ-treated animals exhibited a decrease in body weight (519 g vs 568 g;  $p < 0.001$ ) and plasma insulin (1.6 ng/ml vs 2.8 ng/ml;  $p < 0.01$ ) and an increase in HbA<sub>1c</sub> (9% vs 7%;  $p < 0.001$ ), plasma glucose (15.7

mM vs 8.3 mM;  $p<0.001$ ), and TAG (0.36 mM vs 0.2 mM;  $p<0.001$ ) vs vehicle-treated animals. In addition, STZ treatment significantly impaired glucose tolerance in an OGTT (AUC 52.2 mM.h vs 22.8 mM.h in vehicle-treated animals;  $p<0.001$ ). Empagliflozin had no statistically significant effect on body weight or food intake compared with STZ-treated controls, but improved the glucose control of diabetic rats in an OGTT (AUC 24.2 mM.h vs 52.2 mM.h;  $p<0.001$ ) and reduced overnight fasting glucose prior to the OGTT (6.61 mM vs 10.71 mM;  $p<0.001$ ). At Day 29, reductions in HbA1c (7.6% vs 9.0%;  $p<0.001$ ), plasma glucose (7.6 mM vs 15.7 mM;  $p<0.001$ ), insulin (0.7 ng/ml vs 1.6 ng/ml;  $p<0.01$ ) and TAG (0.21 mM vs 0.36 mM  $p<0.01$ ) were observed in empagliflozin-treated rats versus STZ-treated controls. In contrast, exenatide reduced body weight (8.2%;  $p<0.001$ ) and average daily food intake (15.9g vs 20.0g  $p<0.001$ ) but did not significantly improve glucose control in an OGTT ( $p=NS$ ) nor alter fasting glucose ( $p=NS$ ) versus STZ-treated control rats. Although chronic infusion of exenatide reduced plasma TAG (0.28 mM vs 0.36 mM  $p<0.05$ ) and glycerol (0.10 mM vs 0.18 mM;  $p<0.05$ ), HbA1c, plasma glucose and insulin were not significantly altered versus STZ-treated control rats.

**Conclusion:** Empagliflozin treatment significantly improved glucose control and HbA1c in an animal model in which insulin secretion was markedly impaired. In contrast, despite reducing body weight, exenatide did not improve overall glycaemic control. Significant efficacy with empagliflozin in this insulinopenic model of diabetes confirms the potential use of empagliflozin in the treatment of both type 1 and type 2 diabetes.

### LX4211, a dual inhibitor of SGLT2 and SGLT1 enhances the effects of sitagliptin in patients with type 2 diabetes mellitus

B. Zambrowicz<sup>1</sup>, I. Ogbaa<sup>1</sup>, D. Powell<sup>1</sup>, P. Banks<sup>1</sup>, A. Turnage<sup>1</sup>, K. Frazier<sup>1</sup>, K.A. Boehm<sup>1</sup>, J. Freiman<sup>1</sup>, P. Lapuerta<sup>1</sup>, D. Ruff<sup>2</sup>, A. Sands<sup>1</sup>;

<sup>1</sup>Lexicon Pharmaceuticals, Inc., The Woodlands, <sup>2</sup>Healthcare Discoveries LLC d/b/a ICON Development Solutions, San Antonio, USA.

**Background and aims:** Combination therapy is often required in patients with type 2 diabetes mellitus (T2DM) to achieve glycemic control. LX4211 is a potent inhibitor of SGLT1 in the gastrointestinal (GI) tract and SGLT2 in the kidney. Local SGLT1 inhibition has been shown to stimulate secretion of GI hormones that play a role in glycemic control and appetite suppression. In this mechanistic study, we investigated the pharmacodynamic (PD) effects of the combination of LX4211 plus sitagliptin, a DPP-4 inhibitor, compared to either agent alone.

**Materials and methods:** 18 diabetic patients received single doses of either LX4211 (400 mg), sitagliptin (100 mg), or LX4211+sitagliptin on Days 1, 8, or 15 according to a balanced 3x3 crossover design with a 7-day washout period between each dosing day. PD parameters assessed included urinary glucose excretion (UGE), postprandial glucose (PPG), insulin, peptide YY (PYY), and total and active glucagon-like peptide 1 (GLP-1).

**Results:** All patients completed the study. There were no serious adverse events, deaths or discontinuations due to adverse events. The drug combination differed from sitagliptin for the PD parameters below. Data are presented as AUC<sub>0-last</sub> adjusted means, except for UGE.

**Conclusion:** LX4211 and sitagliptin, combined, significantly increased both active and total GLP-1 as compared to sitagliptin alone, and produced substantial reductions in PPG with lower endogenous insulin levels. LX4211 and sitagliptin appear to have complementary mechanisms of action that may provide a novel approach to combination therapy for T2DM.

## 773

### LX4211, a dual SGLT1/SGLT2 inhibitor shows a favourable gastrointestinal and genitourinary safety profile in type 2 diabetes mellitus patients and healthy subjects

J. Freiman, G.-L. Ye, I. Ogbaa, K.A. Boehm, A. Turnage, K. Frazier, A. Sands, B. Zambrowicz;

Lexicon Pharmaceuticals, Inc., The Woodlands, USA.

**Background and aims:** Selective SGLT2 inhibitors are designed to treat T2DM by reducing glucose reabsorption by the kidney, resulting in urinary glucose excretion. An increased incidence of genitourinary (GU) infections has been observed with these agents. Because patients with genetic mutations in SGLT1, that completely inhibit SGLT1 function, experience glucose-galactose malabsorption, most SGLT inhibitors selectively inhibit SGLT2 to avoid the theoretical risk of diarrhea resulting from pharmacologic inhibition of SGLT1 inhibition. In clinical trials to date, LX4211, a potent dual inhibitor of SGLT1 and SGLT2, has shown both significantly improved glycemic parameters and a favorable gastrointestinal (GI) safety profile. This overview of LX4211 clinical studies evaluates the occurrence of adverse events (AEs) that may be associated with the pharmacologic action of LX4211.

**Materials and methods:** LX4211 was studied at single and multiple doses in healthy subjects and patients with T2DM (Figure 1) at doses ranging from 5 to 500 mg/day. LX4211 safety was assessed through AEs collected from the first dose to 30 days after the last dose. Relevant AEs were reviewed for each study.

**Results:** Of the 12 AEs of diarrhea, 5 occurred on LX4211 out of 1090 person days (PD), 3 with metformin out of 18 PD, and 4 with LX4211+metformin out of 18 PD. All resolved within 1 day and were generally mild. There were no episodes of hypoglycemia, with no deaths, serious AEs, or AEs leading to discontinuation. No GU infection was reported in any LX4211-treated subject.

**Conclusion:** In clinical studies to date, LX4211 is well-tolerated with no evidence of clinically significant hypoglycemia, diarrhea, or GU infections.

**LX4211 increases serum GLP-1 and PYY levels after oral glucose challenge in mice by inhibiting SGLT1-mediated intestinal glucose absorption**

D. Powell, M. Smith, S. Zhao, J. Greer, A. Harris, C. DaCosta, A. Sands, B. Zambrowicz, Z.-M. Ding;  
Lexicon Pharmaceuticals, Inc., The Woodlands, USA.

**Background and aims:** LX4211, a dual SGLT1/SGLT2 inhibitor, is designed to reduce renal glucose reabsorption by inhibiting SGLT2 and intestinal glucose absorption by inhibiting SGLT1. Increased intestinal glucose levels secondary to SGLT1 inhibition should trigger release of intestinal hormones such as glucagon-like peptide (GLP)-1 and peptide YY (PYY). We asked if oral glucose increases levels of cecal glucose and serum GLP-1 and PYY in mice treated with LX4211, and if these findings are recapitulated in SGLT1 or SGLT2 knockout (KO) mice.

**Materials and methods:** Study 1: Wild-type (WT) mice raised on glucose-containing diet received vehicle or LX4211 (60 mg/kg) by gavage; 30 min later these mice, along with SGLT1 and SGLT2 KO and WT littermate mice raised on glucose-free diet, received a glucose-containing meal (9.2 g glucose/kg, 2.5 g protein/kg, 0.6 g fat/kg) by gavage and were studied 3 hr later. Study 2: 30 min after WT mice received vehicle or LX4211 (60 mg/kg) by gavage, they were gavaged different doses of glucose (N = 5/group); total GLP-1 AUC (nM x min) was then estimated over the next 6 hr, and data were analyzed by ANOVA followed by Bonferroni-Dunn post-hoc test.

**Results:** The results for Study 1 are presented in Table 1.

Table 1

Mice	Cecal G (mg)	Total GLP-1 (pM)	Active GLP-1 (pM)	PYY (ng/ml)
WT + Vehicle	1.2 ± 0.4	55 ± 2	7.2 ± 0.6	0.9 ± 0.1
WT + LX4211	18.9 ± 2.2***	161 ± 15***	16.3 ± 2.1***	2.2 ± 0.3**
SGLT1 WT	0.1 ± 0.1	36 ± 4	2.7 ± 0.2	1.0 ± 0.1
SGLT1 KO	16.7 ± 5.4*	158 ± 14***	12.5 ± 3.8*	2.2 ± 0.6*
SGLT2 WT	0.7 ± 0.5	52 ± 2	7.0 ± 0.1	1.6 ± 0.1
SGLT2 KO	0.7 ± 0.4	53 ± 4	7.1 ± 0.4	1.3 ± 0.1

Values are mean ± SE; N > 4; unpaired t test. \* p < 0.05; \*\* p < 0.01; \*\*\* p < 0.001

For Study 2, Total GLP-1 AUC (mean ± SE) was 18 ± 3 (vehicle) vs 42 ± 4 (LX4211) after 2 g glucose/kg (p > 0.05), 19 ± 1 (vehicle) vs 59 ± 6 (LX4211) after 4 g glucose/kg (p > 0.05), 29 ± 4 (vehicle) vs 84 ± 12 (LX4211) after 6 g glucose/kg (p < 0.01), and 25 ± 4 (vehicle) vs 160 ± 36 (LX4211) after 8 g glucose/kg (p < 0.001).

**Conclusion:** Oral glucose increased levels of intestinal glucose and serum GLP-1 and PYY in LX4211-treated mice, findings that were recapitulated in SGLT1, but not SGLT2, KO mice. These data suggest that LX4211 increases serum GLP-1 and PYY levels after an oral glucose challenge by inhibiting intestinal SGLT1.

## 775

**LX4211, a dual inhibitor of SGLT1 and SGLT2, results in postprandial glucose reductions in healthy subjects**

P. Lapuerta<sup>1</sup>, I. Ogbaa<sup>1</sup>, D. Powell<sup>1</sup>, P. Banks<sup>1</sup>, A. Turnage<sup>1</sup>, K. Frazier<sup>1</sup>, K.A. Boehm<sup>1</sup>, J. Freiman<sup>1</sup>, D. Ruff<sup>2</sup>, A. Sands<sup>1</sup>, B. Zambrowicz<sup>1</sup>;

<sup>1</sup>Lexicon Pharmaceuticals, Inc., The Woodlands, <sup>2</sup>Healthcare Discoveries LLC d/b/a ICON Development Solutions, San Antonio, USA.

**Background and aims:** SGLT2 is the target of several investigational compounds that aim to treat type 2 diabetes mellitus (T2DM). LX4211 is a potent systemic inhibitor of SGLT2 that also inhibits SGLT1 locally in the gastrointestinal (GI) tract. In prior clinical studies, dual inhibition by LX4211 provided glycemic control and metabolic benefits without triggering clinically significant GI side effects. In this study we explored the impact of timing of the dosing regimen on a variety of pharmacodynamic (PD) parameters including postprandial glucose (PPG), fasting plasma glucose (FPG), and insulin.

**Materials and methods:** 12 healthy subjects were enrolled, sequestered, and randomly assigned to LX4211 (n=10) or placebo (n=2). Subjects received LX4211 two (2) hours prior to breakfast for 7 days to establish a steady state, followed by dosing at 5 different times relative to meal, in a Latin Square design balanced for first order carryover effects, on Days 8-12. PD parameters, including PPG, FPG, and insulin were assessed. Safety and tolerability were also evaluated throughout the study.

**Results:** All 12 subjects completed the study. Results across dosing times were comparable. All adverse events (AE) were mild and infrequent; no events were deemed to be related to the administration of LX4211.

**Conclusion:** LX4211 produced marked suppression of postprandial glucose excursion and hyperinsulinemia after breakfast with either morning or split dose, without producing hypoglycemia or diarrhea in healthy subjects.

Days 8-12, change from baseline (Day -1):

Dose Schedule→ PD Variable↓	Immediately prior to breakfast	Split dose <sup>a</sup> (AM/PM)
FPG (mg/dL) (95% CL)	-6.12 (-8.26, -3.98)†	-6.68 (-8.81, -4.54)†
PPG (mg•hr/dL) AUC <sub>0-last</sub> (95% CL) <sup>b</sup>	-74.71† (-99.75, -49.67)	-103.19† (-128.23, -78.15)
Insulin (μU•hr/mL) AUC <sub>0-last</sub> (95% CL) <sup>b</sup>	-193.71† (-189.51, -134.14)	-163.65† (-191.33, -135.97)

† p < 0.001 of within schedule comparison vs Day -1

<sup>a</sup> Split dose was taken 1 hour prior to both breakfast and dinner

<sup>b</sup> AUC<sub>0-last</sub> was calculated from 0-minutes to 13-hours postdose

Clinical Trial Registration Number: NCT01334242

## 776

### The combination of LX4211 and DPP4 inhibition synergistically increases serum levels of active GLP-1 after glucose challenge in mice

Z.-M. Ding, M. Smith, S. Zhao, J. Greer, A. Harris, A. Sands, B. Zambrowicz, D. Powell;  
Lexicon Pharmaceuticals, Inc., The Woodlands, USA.

**Background and aims:** LX4211, a dual SGLT1/SGLT2 inhibitor, increases serum levels of total GLP-1 and active GLP-1 (aGLP-1) after an oral glucose challenge. These increases result from inhibition of intestinal SGLT1 by LX4211, which delays small intestinal glucose absorption and triggers increased release of GLP-1 by the gastrointestinal tract. Sitagliptin is a DPP4 inhibitor that increases aGLP-1 levels by inhibiting DPP4-mediated aGLP-1 inactivation. We asked whether the combination of LX4211 and Sitagliptin would increase aGLP-1 levels more than either compound alone after oral glucose challenge.

**Materials and methods:** Male C57BL/6J mice, 27 weeks of age and fed 45% lard diet from weaning, received either vehicle, LX4211 (60 mg/kg), Sitagliptin (30 mg/kg), or both LX4211 and Sitagliptin by oral gavage for 14 days. 30 minutes after their last dose, these mice received a glucose-containing meal (9.2 g glucose/kg, 2.5 g protein/kg, 0.6 g fat/kg) by oral gavage. Serum aGLP-1 levels were measured on samples obtained at baseline and at 0.5-, 1-, 3- and 6-hours after glucose gavage using the Millipore aGLP-1 ELISA kit. Data were analyzed by 2-way ANOVA.

**Results:** As shown in the figure below, a significant interaction of LX4211 and Sitagliptin was demonstrated at baseline and at 1-, 3- and 6-hours post glucose challenge, indicating a synergistic increase in aGLP-1 with the combination of LX4211 and Sitagliptin compared to effects seen with each compound alone. Four additional studies confirmed these findings.

**Conclusion:** These data suggest that SGLT1 inhibition by LX4211 and DPP-4 inhibition by Sitagliptin increase aGLP-1 by complementary mechanisms of action which, when combined, lead to a synergistic increase in aGLP-1 levels that may be advantageous to patients with T2DM.

## 777

### Health-related quality of life (EQ-5D) among type 2 diabetes mellitus patients treated with dapagliflozin for 24 weeks

A. Ingelgård<sup>1</sup>, S. Grandy<sup>2</sup>, A. Langkilde<sup>1</sup>, J.E. Sugg<sup>2</sup>, S.J. Parikh<sup>2</sup>;  
<sup>1</sup>AstraZeneca, Mölndal, Sweden, <sup>2</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin is a first in class, oral sodium-glucose co-transporter 2 (SGLT2) inhibitor, in clinical development for the treatment of type 2 diabetes mellitus (T2DM). Dapagliflozin lowers blood glucose by increasing urinary glucose excretion and is associated with improvements in HbA1c and reductions in body weight. This study evaluated the health status and health-related quality of life (HRQOL) among T2DM patients treated with dapagliflozin in a randomised clinical trial.

**Materials and methods:** Subjects with T2DM (BMI  $\geq 25$  kg/m<sup>2</sup>; men 56%, women 44%; mean age, 61 years) who had inadequate glycaemic control on metformin (MET) alone were enrolled in a 24-week, international, double-blind, randomised, placebo-controlled study to evaluate the effect of dapagliflozin in combination with MET on total body weight. Subjects completed the EQ-5D questionnaire at baseline and at week 24. Subjects treated with dapagliflozin 10 mg + MET (n = 87) were compared with subjects treated with placebo + MET (n = 89), based on an ANCOVA model with treatment group and gender as effects and baseline value as a covariate.

**Results:** EQ-5D index baseline means (SD) were 0.85 (0.16) and 0.82 (0.15) for dapagliflozin and placebo, respectively. Corresponding 24-week values were 0.88 (0.17) and 0.87 (0.16), respectively. The ANCOVA model indicated no difference (-0.01; CI [-0.05, 0.03]; p-value 0.49). EQ-5D visual analog scale (VAS) baseline means (SD) were 72.8 (19.39) and 73.7 (15.49) for dapagliflozin and placebo, respectively. Corresponding 24-week values were 77.4 (15.21) and 78.3 (10.65), respectively. The ANCOVA model indicated no difference (-0.6; CI [-3.9, 2.8]; p-value 0.74).

**Conclusion:** Results indicated that the patients maintained high HRQOL scores from baseline to week 24 in both treatment groups as measured by EQ-5D index and VAS. Health status and HRQOL were maintained at a high level during treatment with dapagliflozin, a novel, selective SGLT2 inhibitor.

Clinical Trial Registration Number: NCT00855166

## PS 060 Incretins and atherosclerosis

778

### The anti-atherosclerosis effect of dipeptidyl peptidase-4 inhibitor is mainly attributable to increased incretins in apolipoprotein-E null mice

T. Hirano, M. Terasaki, M. Nagashima, Y. Nogi, K. Notomi;  
Diabetes, Metabolism, and Endocrinology, Showa University School of Medicine, Tokyo, Japan.

**Background and aims:** Several recent reports have revealed that dipeptidyl peptidase (DPP)-4 inhibitor suppresses atherosclerosis in hypercholesterolemic mice. It remains to be seen, however, whether this effect is mainly attributable to increased active incretins; glucagon-like peptide-1 (GLP-1) and/or glucose-dependent insulintropic polypeptide (GIP).

**Materials and methods:** Seventeen-week-old apolipoprotein E-null (*ApoE*<sup>-/-</sup>) mice fed an atherogenic diet were administered a DPP-4 inhibitor, vildagliptin (100 micromol/kg/day), in drinking water for 4 weeks. During vildagliptin administration, the animals were subcutaneously infused (via osmotic minipumps) with either saline, a GLP-1 receptor (R) blocker (Exendin-9, 22 nmol kg<sup>-1</sup> day<sup>-1</sup>), a GIPR blocker ((Pro3) GIP, 25 nmol kg<sup>-1</sup> day<sup>-1</sup>), or both. Aortic atherosclerosis and oxidized-low-density-lipoprotein-induced foam cell formation in exudate peritoneal macrophages were determined. The direct effect of mouse DPP-4 (CD26: 100–500 ng/ml) or DPP-4 inhibitor (PKF-275-055: 20 micromol) on foam cell formation was also determined.

**Results:** Orally administered vildagliptin increased plasma levels of active GLP-1 by 3.5-fold without affecting food intake, body weight, blood pressure, or plasma parameters (excluding a mild cholesterol reduction). Vildagliptin significantly suppressed total aortic atherosclerotic lesions, atheromatous plaque in the aortic root, and macrophage accumulation in the aortic wall (60% reduction,  $p < 0.0001$ ). Likewise, vildagliptin suppressed foam cell formation by 40% in exudate peritoneal macrophages. Exendin-9 or (Pro3)GIP partially attenuated the vildagliptin-induced suppression of atherosclerosis and macrophage foam cell formation, whereas the combination of both receptor blockers virtually abolished both of these vildagliptin effects. DPP-4 or DPP-4 inhibitor did not affect the foam cell formation *in vitro*.

**Conclusion:** DPP-4 inhibitor substantially suppresses atherosclerosis in *ApoE*<sup>-/-</sup> mice. This suppressive effect is mainly attributable to increased levels of both GLP-1 and GIP, but not to the inactivation of DPP-4.

779

### Improved endothelial cell function and inflammation after replacement of insulin by liraglutide in combination with metformin and sulfonylurea in type 2 diabetic patients

T. Kamada<sup>1</sup>, E. Tanoue<sup>1</sup>, T. Harada<sup>1</sup>, M. Kurano<sup>1</sup>, C. Hisadome<sup>1</sup>, T. Kamikubo<sup>2</sup>, H. Sameshima<sup>2</sup>;

<sup>1</sup>Diabetes, Imamura Bun-in Hospital, <sup>2</sup>Nanami Clinic, Kagoshima, Japan.

**Background and aims:** Glucagon-like peptide-1 (GLP-1) receptor agonists improve glycemic control in type 2 diabetic patients (T2DM), being associated with weight loss and a low risk of hypoglycemia. They are also suggested to have a beneficial effect on myocardium, endothelium and vasculature, as well as potential anti-inflammatory and antiatherogenic actions. In diabetes, both impaired endothelial cell function and inflammatory condition are considered important in the progression of the disease itself and atherosclerosis. We studied the effect of replacement of insulin by liraglutide on endothelial cell function and inflammatory biomarker in T2DM treated with insulin in combination with oral hypoglycemics.

**Materials and methods:** Thirty-three T2DM patients (male 14, female 19; age: 56±12, BMI: 26.1±4.2) were enrolled to study. They were treated with insulin (total daily dose: 20.2±11.7 (5–46) U) in combination with metformin and sulfonylurea. Insulin was replaced by liraglutide 0.9mg, and clinical parameters and post ischemic flow-mediated dilatation (FMD) of brachial artery were evaluated after 3 and 6 months. The clinical parameters included HbA1c, 1,5-anhydroglucitol (1,5AG): a marker of postprandial hyperglycemia, serum C-peptide (sCP), high sensitivity C-reactive protein (hsCRP) and estimated GFR (eGFR). The FMD was measured in fasting state. Foods containing caffeine and smoking were prohibited for 10hrs before the measurement. ANOVA and Freedman plus Wilcoxon tests were performed for statistical analysis.

**Results:** 1) HbA1c was significantly improved after replacement of insulin by liraglutide for 3 and 6 months (from 7.88±0.95 to 7.19±0.0.90 and 7.50±0.91%,

$p < 0.001$  and  $p < 0.006$  vs. before) without hypoglycemic episode. The improvement was more apparent in the patients having higher sCP levels, less daily insulin doses. 2) The changes of fasting blood glucose and 1,5AG were not statistically significant after 3 and 6 months. 3) Average body weight was decreased -2kg after 3 months and -1Kg after 6 months as compared before. 4) FMD was significantly improved after 6 months (from 4.56±2.22 to 4.70±2.42 and 5.92±2.51%;  $p < 0.05$  vs. before). The proportion of patients FMD above cutoff value 6% was 24% of total before the replacement, but it increased up to 54% after 6 months liraglutide treatment. The improvement of FMD was independent of either weight loss or changes of blood glucose (HbA1c, FBS and 1,5AG). 5) Blood pressure was not altered after the replacement, but eGFR were significantly increased after 6 months (from 74.1±11.3 to 77.4±12.5 ml/min/1.73m<sup>2</sup>,  $p < 0.05$ ). 7) HsCRP was significantly decreased after 6 months as compared before (from 0.12±0.15 to 0.04±0.04mg/l,  $p < 0.05$ ).

**Conclusion:** Replacement of insulin by liraglutide in combination with metformin and sulfonylurea improved HbA1c and body weight in T2DM patients without hypoglycemia. Impaired FMD in T2DM was recovered after liraglutide treatment, which might be brought about by its direct effect on endothelial function. Treatment with liraglutide also decreased hsCRP, a marker of inflammation. Our results suggest that replacement of insulin by liraglutide might be beneficial for the treatment of vasculopathy of T2DM.

780

### The GLP-1 receptor agonist liraglutide attenuates atherosclerotic lesion development and enhances plaque stability in an ApoE<sup>-/-</sup> mouse model

A.E. Dear<sup>1</sup>, T. Gaspari<sup>2</sup>, I. Welungoda<sup>2</sup>, R.E. Widdop<sup>2</sup>, R.W. Simpson<sup>3</sup>;

<sup>1</sup>Medicine, <sup>2</sup>Pharmacology, <sup>3</sup>Endocrinology, Monash University, Melbourne, Australia.

**Background and aims:** The once daily GLP-1 receptor (GLP-1R) agonist, liraglutide, has been approved as a new treatment for type 2 diabetes. Liraglutide improves glycaemic control, lowers body weight and is the subject of clinical trials to evaluate effects on cardiovascular disease. We have previously demonstrated liraglutide-mediated attenuation of tumour necrosis factor alpha (TNFα) induced plasminogen activator inhibitor type 1 (PAI-1) and vascular cell adhesion molecule expression in human vascular endothelial cells *in vitro* and significant improvement in endothelial function and attenuation of adhesion molecule expression *in vivo* in the ApoE<sup>-/-</sup> mouse model. The current study aimed to determine the *in vivo* effect of liraglutide on atherosclerotic plaque formation and stability in the ApoE<sup>-/-</sup> mouse model.

**Materials and methods:** *In vivo* experiments utilized early onset disease (1) or established disease (2) protocols: (1) 17 week old ApoE<sup>-/-</sup> mice maintained on a normal chow diet were simultaneously commenced on a high fat diet and either saline (vehicle), liraglutide (300µg/kg twice daily, s.c.) or liraglutide + exendin-9 (150pmol/kg/min s.c., osmotic mini-pump) for 4 weeks or (2) 18 week old ApoE<sup>-/-</sup> mice maintained on a high fat diet for 12 weeks were treated with a regime identical to protocol 1 for 4 weeks.

**Results:** Oil red O staining and intima to media ratio (IMR) analysis of atherosclerotic plaques from the aorta and brachiocephalic artery (BCA) identified a significant reduction in lipid deposition and IMR in liraglutide treated mice from protocol 1. A statistically significant increase in vascular smooth muscle cell (SMC) content, as assessed by α-smooth muscle actin staining, of BCA atherosclerotic lesions in liraglutide-treated mice from protocol 1 was identified. The increase in SMC composition and decrease in lipid deposition in plaques from the BCA of protocol 1 mice are suggestive of a plaque stabilising effect associated with liraglutide treatment. Attenuation of the liraglutide-mediated plaque stabilising effect by concurrent administration of the GLP-1R antagonist exendin-9 confirmed the GLP-1R-dependence of this effect. Vascular reactivity studies identified no apparent endothelial dysfunction in the aorta of mice from protocol 1 however liraglutide treatment significantly attenuated the endothelial dysfunction in mice from protocol 2.

**Conclusion:** Together these results suggest a potential therapeutic benefit of GLP-1 receptor activation by liraglutide in the attenuation of early atherogenesis and stabilisation of existing atherosclerotic disease.

**Long-term administration of exenatide and changes in body weight and markers of cardiovascular risk: a comparative study with glimepiride**

R. Simo<sup>1</sup>, B. Guerci<sup>2</sup>, G. Schernthaner<sup>3</sup>, B. Gallwitz<sup>4</sup>, J. Guzman<sup>5</sup>, F. Dotta<sup>6</sup>, A. Festa<sup>7</sup>, H. Sapin<sup>8</sup>, S. Chen<sup>9</sup>, J. Kiljanski<sup>10</sup>;

<sup>1</sup>Vall d'Hebron Research Institute, Barcelona, Spain, <sup>2</sup>Brabo Hospital & CIC, Nancy, France, <sup>3</sup>Rudolfstiftung Hospital, Vienna, Austria, <sup>4</sup>Eberhard Karls University, Tübingen, Germany, <sup>5</sup>Celaya Center for Specialist Medicine, Guanajuato, Mexico, <sup>6</sup>Policlinico Le Scotte, Siena, Italy, <sup>7</sup>Lilly Austria, Vienna, Austria, <sup>8</sup>Lilly France, Paris, France, <sup>9</sup>Amylin Pharmaceuticals, Inc., San Diego, USA, <sup>10</sup>Lilly Polska, Warsaw, Poland.

**Background and aims:** Type 2 diabetes is associated with elevated risk of cardiovascular (CV) events and it is important to examine whether anti-diabetes medications affect CV risk. Data relating to CV risk factors were examined from the EUROpan EXenAtide (EUREXA) clinical study, which compared glycaemic control during treatment with exenatide twice daily (EXE) versus glimepiride once daily (GLI), added to metformin.

**Materials and methods:** In the long-term, randomised, parallel-group, open-label study, patients with inadequate glycaemic control with metformin alone received add-on EXE (N=511) or GLI (N=508). Patients with inadequate HbA1c with EXE or GLI (HbA1c >9% at any visit or >7% at 2 successive visits, excluding first follow-up visit) were discontinued (EXE n=203, GLI n=262) and offered alternative therapy. Body weight, waist circumference, lipid profiles, blood pressure (BP), and high sensitivity C-reactive protein (hsCRP) concentration were evaluated throughout, with analysis using mixed model repeated measures with terms for baseline value, treatment, visit and interaction.

**Results:** Patients had overall baseline mean age 56 y, diabetes duration 6 y, BMI 32.5 kg/m<sup>2</sup> and HbA1c 7.4%. Mean (SD) baseline weight was 92.6 (16.6) and 90.9 (15.1) kg in EXE and GLI treatment groups, respectively; weight decreased by -3.4 (3.9) kg with EXE and increased by +1.0 (2.9) kg with GLI at 6 mo, with a significant between-group difference from 6 mo to 3 y (3 y difference -3.7 kg, *P*<0.001). Baseline waist circumference was 108.3 (11.8) and 107.6 (11.5) cm in EXE and GLI groups, respectively, which decreased by -2.7 (4.7) cm with EXE and changed by +0.2 (3.8) cm with GLI at 6 mo, with a significant between-group difference maintained from 6 mo (difference -2.8 cm, *P*<0.001) to 3 y (-4.5 cm, *P*<0.001). Baseline systolic BP was 132.9 (15.7) and 133.6 (15.4) mmHg, respectively, which decreased with EXE and was unchanged with GLI, with a between-group difference from 6 mo (-3.6 mmHg, *P*<0.001) to 3 y (-5.2 mmHg, *P*<0.001). Serum total and LDL cholesterol did not differ between groups. Mean baseline HDL cholesterol was 1.26 (0.30) and 1.25 (0.32) mmol/L, respectively, and was increased to a greater extent with EXE than with GLI at 1 y (difference +0.05 mmol/L, *P*=0.002) and 3 y (+0.06 mmol/L, *P*=0.001). Mean baseline triglyceride was 1.95 (1.19) and 2.02 (1.29) mmol/L, respectively, and was decreased to a greater extent with EXE than with GLI at 2 y (difference -0.20 mmol/L, *P*=0.017) and 3 y (-0.26 mmol/L, *P*=0.004). Baseline hsCRP was 4.8 (7.7) and 4.2 (5.1) mg/L, respectively, and decreased with EXE but not GLI, with a between-group difference from 1 y (-1.3 mg/L, *P*=0.011) to 3 y (-1.2 mg/L, *P*=0.004).

**Conclusion:** In patients with type 2 diabetes randomised to EXE in the EUREXA study, cardiovascular risk factors, including weight, BP, and hsCRP, were significantly improved compared with those for patients randomised to GLI, as add-on to metformin. The differences between EXE- and GLI-treated patients were apparent from 1 y through to 3 y of treatment.

Clinical Trial Registration Number: NCT00359762

## 782

**Effects of liraglutide on plasma ghrelin concentrations and oxidative stress in patients with type 2 diabetes: a 2-month prospective pilot study**

M. Rizzo<sup>1,2</sup>, G. Li Volti<sup>3,2</sup>, A. Patti<sup>1</sup>, I. Barbagallo<sup>3</sup>, V. Di Bartolo<sup>1</sup>, V. Giglio<sup>1</sup>, A. Tamburello<sup>1</sup>, A. Zabbara<sup>1</sup>, N. Abate<sup>4</sup>, G. Montalto<sup>1</sup>;

<sup>1</sup>University of Palermo, Italy, <sup>2</sup>Euro-Mediterranean Institute of Science and Technology, Palermo, Italy, <sup>3</sup>University of Catania, Italy, <sup>4</sup>Division of Endocrinology, The University of Texas Medical Branch, Galveston, USA.

**Background and aims:** Liraglutide is an effective hypoglycemic agent recently approved in Italy for clinical use in patients with type 2 diabetes. Since cardiovascular disease is the main cause of morbidity and mortality in this patient population, it is important to assess the effects of liraglutide on atherogenesis. To this goal, we evaluated the effects of intervention with liraglutide on glucose-independent mechanisms of atherogenesis. Since recent findings

suggest that plasma ghrelin concentrations may be affected by liraglutide and that ghrelin may play an important anti-atherogenic role, we hypothesized that liraglutide could have an effect on plasma ghrelin concentrations. We also evaluated whether these glucose-independent metabolic effects of liraglutide would include reduction in oxidative stress, a major contributor to atherogenesis.

**Materials and methods:** Twenty patients with type 2 diabetes (10 men and 10 women, age: 57±13 years) were enrolled in a prospective pilot study to assess the effect of combined therapy with liraglutide (0.6mg/daily for the first 2 weeks, followed by a dose of 1.2mg/daily) and metformin (1500mg/daily) on plasma ghrelin concentrations (measured by ELISA) and oxidative stress status, measured by determination of reactive oxygen species (using a fluorescent probe 2,7-dichlorofluorescein), serum lipid hydroperoxides (following the oxidation of Fe<sup>2+</sup> to Fe<sup>3+</sup> in the presence of xylenol orange) and serum total thiol groups (in 200 µl of serum, using a spectrophotometric assay based on the reaction of thiol groups with 2,2-dithio-bis-nitrobenzoic acid). Patients were newly diagnosed or previously treated subjects on stable doses of oral hypoglycemic agents. All samples were obtained in the morning, after a 16-18 hours fasting. Statistical analysis was performed using non-parametric Wilcoxon paired test and the Spearman correlation method.

**Results:** At baseline patients had a body-mass-index (BMI) of 28.7±5.3, with average fasting glucose 8.7±3.6 mmol/L and HbA1c 8.0±2.0%. The following changes were recorded after 2 months of therapy: BMI decreased to 28.5±4.3 (*p*=0.9), fasting glucose decreased to 7.6±2.3 mmol/L (*p*=0.0277), and HbA1c to 7.4±1.6% (*p*=0.0378). Plasma ghrelin concentrations increased from 8.2±4.1 to 13.6±7.7 pg/ml (*p*=0.0018), while serum lipid hydroperoxides were reduced from 0.11±0.05 to 0.04±0.07 pg/ml (*p*=0.0283). No significant differences were found in the reactive oxygen species or total thiol groups. Furthermore, changes in plasma ghrelin and lipid hydroperoxides did not correlate with changes in BMI, fasting glucose or HbA1c.

**Conclusion:** Liraglutide has favorable effects on plasma ghrelin concentrations and serum lipid hydroperoxides, both markers of cardio-metabolic risk, in patients with type-2 diabetes after only 2 months of therapy. These data seem not to be related with the known liraglutide effects on plasma glucose concentrations.

## 783

**Exenatide therapy reduced intima-media thickness of carotid artery in patients with type 2 diabetes**

M. Yoshida<sup>1</sup>, N. Yamamoto<sup>1</sup>, A. Saeki<sup>1</sup>, M. Sugino<sup>1</sup>, T. Kuzuya<sup>2</sup>, N. Ohsawa<sup>2</sup>, S. Yoshida<sup>3</sup>, H. Sano<sup>4</sup>, T. Hanafusa<sup>4</sup>;

<sup>1</sup>Internal Medicine, Aino Hospital, Ibaraki City, <sup>2</sup>Aino Institute for Aging Research, Ibaraki City, <sup>3</sup>Yoshida Clinic, Otsu City, <sup>4</sup>Internal Medicine 1, Osaka Medical College, Takatsuki City, Japan.

**Background and aims:** In the treatment of type 2 diabetes, maintenance of good glycemic control including post prandial hyperglycemia from early stage is important for the suppression of cardiovascular events. However, it is not easy by conventional treatments to maintain a long-term good glycemic control while avoiding weight gain. GLP-1 receptor agonist exenatide is expected not only to improve glycemic control but also to exhibit antiatherosclerotic effect. The antiatherosclerotic effects of exenatide were reported in some animal models, but the reports in human are rare. The intima-media thickness (IMT) by ultrasound evaluation of carotid artery is known to be correlated with stroke or myocardial infarction and is a good indicator for arteriosclerosis. This study is aimed to evaluate the efficacy of exenatide for prevention of arteriosclerosis in patients with type 2 diabetes.

**Materials and methods:** The subjects of exenatide group were 56 outpatients with type 2 diabetes (25 men and 31 women), aged 63.8±11.0 years old, BMI 27.7±6.1, and with HbA1c higher than 6.9%, or below 6.9% but with repeating hypoglycemia, by past treatment with OHA and/or insulin. The control group was 50 age-, HbA1c- and BMI-matched subjects with type 2 diabetes. In the exenatide group, exenatide was prescribed in addition to the previous treatment for 12 months, 5 mcg at first, and 10 mcg after 1 month, twice daily in the morning and evening. In sulfonylurea users, the dose of sulfonylurea was reduced to prevent unwanted hypoglycemia. We measured max and mean IMTs of carotid artery with the standardized method using ultrasonography.

**Results:** Three patients discontinued the use of exenatide because of nausea. After the start of exenatide, max IMT was significantly decreased from 2.07±0.79 to 1.91±0.72 (*p*=0.00023), and mean IMT was decreased from 1.09±0.33 to 1.02±0.31 (*p*=0.065) although the difference was not significant. On the other hand in the control group, no significant change was seen in max IMT (from 1.90±0.55 to 1.99±0.68 (*p*=0.296)), nor mean IMT (from

1.08±0.27 to 1.13±0.34 ( $p=0.217$ )). After exenatide treatment, HbA1c, fasting plasma glucose, and 2-hour-postprandial plasma glucose were significantly decreased from 7.7±1.7 to 6.6±0.4% ( $p=0.0038$ ), 140±31 to 105±15mg/dl ( $p=0.0061$ ), 211±50 to 148±29mg/dl ( $p=0.0011$ ), respectively. Also, serum LDL cholesterol and triglyceride levels were decreased from 120±28 to 105±29mg/dl ( $p=0.0098$ ), 181±125 to 145±79mg/dl ( $p=0.0073$ ), and BMI from 27.7±6.1 to 23.5±9.2 ( $p=0.011$ ), respectively. In the control group, the dose of OHA and/or insulin was increased when necessary, and HbA1c, fasting plasma glucose, and 2-hour-postprandial plasma glucose were significantly decreased from 7.6±1.7 to 7.0±0.4% ( $p=0.0072$ ), 148±34 to 112±17mg/dl ( $p=0.0097$ ), and 189±56 to 162±34mg/dl ( $p=0.043$ ), respectively. No significant change was seen in serum LDL cholesterol and triglyceride levels. BMI tended to increase from 26.8±5.8 to 27.5±4.9 ( $p=0.072$ ).

**Conclusion:** Exenatide therapy resulted in the significant decrease of not only body weight, plasma glucose and serum lipid levels but also in max IMT in patients with type 2 diabetes. Exenatide is suggested to prevent worsening of arteriosclerosis in type 2 diabetes.

## 784

### Incidence of cardiovascular events in patients with type 2 diabetes mellitus treated with DPP-4 inhibitors and sulfonylureas in clinical practice in Germany and the UK: a retrospective analysis

M. Dworak<sup>1</sup>, J.-B. Gruenberger<sup>2</sup>, G. Bader<sup>3</sup>, K. Kostev<sup>3</sup>, W. Rathmann<sup>4</sup>, G. Giani<sup>4</sup>

<sup>1</sup>Novartis Pharma GmbH, Nuernberg, Germany, <sup>2</sup>Novartis Pharma AG, Basel, Switzerland, <sup>3</sup>IMS Health, Epidemiology, Frankfurt, Germany,

<sup>4</sup>Institute of Biometrics and Epidemiology, German Diabetes Center, Duesseldorf, Germany.

**Background and aims:** Antidiabetic treatment should be safe and well-tolerated. Dipeptidyl peptidase-4 (DPP-4) inhibitors and sulfonylureas (SUs) are well established treatments for type 2 diabetes (T2DM). However, previous studies have shown that SUs might be associated with increased mortality and cardiovascular risk. So far no data on the incidence of macro- and microvascular events in patients with T2DM treated with DPP-4 inhibitors or SUs by primary care physicians is available.

**Materials and methods:** Data from patients treated with DPP-4 inhibitors ( $n=12,856$ ) and SUs ( $n=12,856$ ) from general medical practices ( $n=1,201$  physicians) in Germany (Disease Analyser database; 04/2007 to 07/2010) were retrospectively analysed after matching for age ( $67 \pm 11$  years) and sex (males: 58%). Hazard ratios (HR; Cox regression) for macro- and microvascular end points (follow-up: 2 years) were adjusted for type of practice (diabetologist), practice region, health insurance status (private), antidiabetic co-medication, hypertension, hyperlipidaemia, episodes of hypoglycaemia, and the Charlson Comorbidity Index. In UK practices, a similar analysis of patients on DPP-4 inhibitors ( $n=796$ ) and on SUs ( $n=796$ ) was carried out.

**Results:** The risk of macrovascular events was 25% lower in patients treated with DPP-4 inhibitors than in those treated with SUs ( $p<0.001$ ). There was a decreased risk of coronary heart disease (HR: 0.75; 95% CI: 0.67, 0.84), incident stroke/transient ischaemic attacks (HR: 0.56; 95% CI: 0.47, 0.68) and peripheral arterial occlusive disease (HR: 0.73; 95% CI: 0.64, 0.84). There was also a trend toward a decreased risk of myocardial infarction (HR: 0.83; 95% CI: 0.69, 1.01). These results were similar for patients with statutory or private health insurance. A similar trend of macrovascular events was found in the UK, however, not statistically significant due to the small number of cases (HR: 0.77; 95% CI: 0.54, 1.10). No association with microvascular complications was observed. Recorded hypoglycaemias were significantly associated with a higher risk of macrovascular complications (HR: 1.6; 95% CI: 1.1, 2.2).

**Conclusion:** This retrospective database analysis showed that compared to treatment with sulfonylureas, prescription use of DPP-4 inhibitors was associated with a reduced incidence of macrovascular events in patients with T2DM in primary care practices.

## 785

### Dipeptidyl peptidase-4 inhibitor (sitagliptin) improves insulin sensitivity and atherosclerosis-related biomarkers in patients with type 2 diabetes

T. Yamane<sup>1</sup>, Y. Suzuki<sup>1</sup>, R. Iwai<sup>2</sup>, Y. Sakuma<sup>2</sup>, S. Yoshida<sup>3</sup>, N. Hashimoto<sup>4</sup>, <sup>1</sup>Diabetes and Metabolic Disease, Asahi General Hospital, Chiba, <sup>2</sup>Clinical Laboratory, Asahi General Hospital, Chiba, Japan, <sup>3</sup>Internal Medicine, Asahi General Hospital, Chiba, <sup>4</sup>Diabetes, Endocrine and Metabolic Disease, Tokyo Women's Medical University, Chiba, Japan.

**Background and aims:** Dipeptidyl peptidase (DPP)-4, an enzyme catalyzing incretins, has been recently reported to be secreted from adipocytes and to be intimately associated with the pathogenesis of obesity and metabolic syndrome. DPP-4 inhibitors therefore may play important roles upon a reduction in insulin resistance and an inhibition of development of atherosclerosis in addition to their glucose lowering effects. The aim of the present study was to examine the effects of sitagliptin, one of DPP-4 inhibitors, upon insulin sensitivity and atherosclerosis in patients with type 2 diabetes.

**Materials and methods:** A total of 131 Japanese patients with type 2 diabetes were enrolled in the study with the informed consent: 73 males/58 females, age  $61 \pm 12$  years, estimated duration of the disease  $11 \pm 7$  years, body mass index  $25.8 \pm 4.7$  kg/m<sup>2</sup>, and HbA<sub>1c</sub>  $7.9 \pm 1.1$  %. They were treated with 50mg of sitagliptin for 24 weeks in addition to the preceding anti-diabetic agents. Laboratory examination included glucose and lipid profiles, indexes of insulin sensitivity (HOMA-IR and quantitative insulin sensitivity check index or QUICKI) and insulin secretion capacity (HOMA- $\beta$  and C-peptide index or CPI). High sensitive C-reactive protein (hsCRP), interleukin (IL)-6, adiponectin, YKL-40 and urinary albumin-to-creatinine ratio (UACR) were assessed as markers for atherosclerosis.

**Results:** Sitagliptin add-on therapy significantly improved parameters for glycaemic control (HbA<sub>1c</sub>:  $7.9 \pm 1.1$  vs.  $7.3 \pm 1.0$  %,  $p<0.0001$ , 1,5-AG:  $8.0 \pm 6.8$  vs.  $9.7 \pm 7.1$  µg/ml,  $p<0.0001$ ) and lipid profiles (LDL-C:  $102 \pm 27$  vs.  $97 \pm 26$ ,  $p<0.01$ , HDL-C:  $52 \pm 11$  vs.  $54 \pm 11$ ,  $p<0.0005$ , FFA:  $575 \pm 243$  vs.  $526 \pm 231$  µEq/l,  $p<0.005$ ). Insulin sensitivity was clearly improved (HOMA-IR:  $3.2 \pm 2.3$ , vs.  $2.7 \pm 2.0$ ,  $p<0.005$ , QUICKI:  $0.336 \pm 0.036$  vs.  $0.344 \pm 0.037$ ,  $p<0.0001$ ), but insulin secretion capacity was unchanged under the fasting conditions. Interestingly serum adiponectin levels were significantly increased ( $8.83 \pm 5.92$  vs.  $9.70 \pm 7.25$  µg/ml,  $p<0.01$ ). In addition, sitagliptin evidently reduced serum levels of inflammatory markers such as hsCRP ( $130 \pm 86$  vs.  $102 \pm 141$  µg/dl,  $p<0.05$ ), IL-6 ( $2.37 \pm 2.12$  vs.  $1.86 \pm 1.07$  pg/ml,  $p<0.01$ ), and YKL-40 ( $116.6 \pm 68.7$  vs.  $105.6 \pm 58.6$  ng/ml,  $p=0.0001$ ). UACR was also decreased ( $47.8 \pm 67.4$  vs.  $39.9 \pm 56.4$  mg/gCre,  $p<0.005$ ).

**Conclusion:** Sitagliptin significantly improved insulin sensitivity and atherosclerosis-related biomarkers associated with the development of inflammation and endothelial dysfunction, suggesting that the agent possesses the action beyond glucose lowering effects. Thus sitagliptin may have some potential roles different from GLP-1 receptor agonists through DPP-4 inhibition.

## 786

### Glucose-dependent insulinotropic polypeptide prevents the progression of macrophage-driven atherosclerosis in diabetic apolipoprotein E-null mice

N. Masaharu, Y. Nogi, M. Terasaki, K. Notomi, M. Tomoyasu, T. Hirano; Department of Medicine, Division of Diabetes, Metabolism, and Endocrinology, Showa University School of Medicine, Shinagawa Tokyo, Japan.

**Background and aims:** We recently reported that glucose-dependent insulinotropic polypeptide (GIP) prevents the development of atherosclerosis in apolipoprotein E-null (Apoe<sup>-/-</sup>) mice. GIP receptors (GIPRs) are found to be severely down-regulated in diabetic animals. We examined whether GIP can exert anti-atherogenic effects in diabetes.

**Materials and methods:** Nondiabetic Apoe<sup>-/-</sup> mice, streptozotocin-induced diabetic Apoe<sup>-/-</sup> mice, and db/db mice were administered GIP (25 nmol/kg/day) or saline (vehicle) through osmotic minipumps for 4 weeks. The animals were assessed for aortic atherosclerosis and for oxidized low-density lipoprotein (ox-LDL)-induced foam cell formation in exudate peritoneal macrophages.

**Results:** Diabetic Apoe<sup>-/-</sup> mice of 21 weeks of age exhibited more advanced atherosclerosis than nondiabetic Apoe<sup>-/-</sup> mice of the same age. GIP infusion in diabetic Apoe<sup>-/-</sup> mice increased plasma total GIP levels by 4-fold without improving plasma insulin, glucose, or lipid profiles. GIP infusion significantly suppressed macrophage-driven atherosclerotic lesions, but this effect was

abolished by co-infusions with [Pro3]GIP, a GIPR antagonist. Ox-LDL-induced cholesterol ester (CE) accumulation in macrophages was 3-fold higher in diabetic Apoe<sup>-/-</sup> mice than in nondiabetic Apoe<sup>-/-</sup> mice. Foam cell formation in macrophages from GIP-infused diabetic Apoe<sup>-/-</sup> mice was suppressed significantly, by 50%. The GIP-induced suppression of foam cell formation was abolished by the co-infusion with [Pro3]GIP. Foam cell formation was 5-fold higher in diabetic db/db mice than in db/mist mice. The GIP infusion attenuated the foam cell formation significantly, by 40%. In vitro infusion of GIP (1 nM) reduced foam cell formation by 15% in macrophages from diabetic Apoe<sup>-/-</sup> mice, and this attenuating effect was weaker than that attained by the same treatment of macrophages from nondiabetic counterparts (35%). While GIPR expression was reduced by only about a half in macrophages from diabetic mice, it was reduced much more dramatically in pancreatic islets from the same animals. Incubation with high glucose (500 mg/dl) for 9–10 days markedly reduced GIPR expression in pancreatic islet cells, but not in macrophages.

**Conclusion:** Chronic administration of GIP remarkably suppressed the progression of atherosclerosis in STZ-induced diabetic Apoe<sup>-/-</sup> mice and suppressed macrophage foam cell formation in both diabetic Apoe<sup>-/-</sup> mice and diabetic db/db mice, even though GIPR expression in macrophages was mildly down-regulated in the diabetic state. This down-regulation of GIPR in macrophages may have been limited enough to permit the suppression of foam cell formation by 4-fold increase of circulating GIP levels.

#### Pioglitazone and bladder malignancy during observational follow-up of PROactive: 6-year update

R. Spanheimer<sup>1</sup>, E. Erdmann<sup>2</sup>, E. Song<sup>3</sup>, A.-R. Van Troostenburg de Bruyn<sup>3</sup>, A. Perez<sup>3</sup>;

<sup>1</sup>Takeda Pharmaceuticals North America, Deerfield, USA, <sup>2</sup>Medical Clinic III, University of Cologne, Germany, <sup>3</sup>Takeda Global Research & Development Center, Deerfield, USA.

**Background and aims:** PROactive was a double-blind, placebo-controlled outcomes study investigating pioglitazone for secondary prevention of macrovascular events in type 2 diabetes. Although there was no difference in the cumulative incidence of overall malignancies between treatment groups (3.7% for pioglitazone vs 3.8% for placebo), an imbalance in the number of diagnosed bladder malignancies was reported (n=14 for pioglitazone vs 5 for placebo). Of the 5238 randomized patients, 3599 (74%) then entered a 10-yr non-interventional observational study with no allocation to study medication, which included reporting of any new malignancies.

**Materials and methods:** An interim 6-yr analysis compared overall and bladder malignancies based on original randomization to pioglitazone or placebo.

**Results:** During the observational period alone (mean 5.8 yr), diagnoses of any malignancy were similar between the two groups (Table), and there were fewer cases of bladder malignancy in the pioglitazone group. For the combined PROactive double-blind and observational periods (up to 9.5 yr in total; mean 8.7 yr), a similar % of patients had a diagnosis of any malignancy or specifically bladder malignancy in the pioglitazone and placebo groups (Table). When pioglitazone usage during the observational period was considered, there was no significant difference in bladder malignancies between those with any and those with no pioglitazone use for both periods combined (Hazard ratio=0.98, 95% CI [0.55, 1.77], p=0.96).

**Conclusion:** The imbalance in bladder cancer incidence during the double-blind period of PROactive did not persist in this interim analysis of the observational follow-up study.

Number (%) of patients with a diagnosis of any malignancy or specifically bladder malignancy during PROactive double-blind period and observational follow-up according to original double-blind therapy and regardless of subsequent treatment				
Treatment Period and Endpoint	Original treatment during double-blind period		Relative risk	95% CI
	Pioglitazone	Placebo		
Observational period only	(n=1820)	(n=1779)		
Any malignancy	164 (9.0%)	156 (8.8%)	1.03	[0.83, 1.27]
Bladder malignancy	10 (0.5%)	17 (1.0%)	0.57	[0.26, 1.25]
Double-blind period + observational period	(n=2605)	(n=2633)		
Any malignancy	257 (9.9%)	247 (9.4%)	1.05	[0.89, 1.24]
Bladder malignancy	23 (0.9%)	22 (0.8%)	1.06	[0.59, 1.89]

#### Efficacy of sulfonylurea treatment for glycaemic control in diabetes: a systematic review and meta-analysis

A.J. Farmer<sup>1,2</sup>, R.J. Stevens<sup>1,2</sup>, A. Tochlin<sup>3</sup>, T.W.C. Lung<sup>4</sup>, J.A. Hirst<sup>1,2</sup>;

<sup>1</sup>Department of Primary Care Health Sciences, University of Oxford, UK,

<sup>2</sup>National Institute for Health Research School for Primary Care Research, Oxford, UK, <sup>3</sup>Oxford Medical School, University of Oxford, UK, <sup>4</sup>University of Sydney, Sydney School of Public Health, Australia.

**Background and aims:** Sulfonylureas are the oldest class of oral medication for treating diabetes, but the size of treatment on glycated haemoglobin levels (HbA1c) is not well understood. An American Diabetes Association Consensus report from 2009 estimated that sulfonylureas lower HbA1c by 1.5%, based on the results from a single trial. A recent systematic review of 6 trials estimated the reduction in HbA1c to be closer to 1%. We aim to identify randomised controlled trials of sulfonylurea treatment as a monotherapy and added-on to another glucose-lowering medication to examine their effect on HbA1c.

**Materials and methods:** Three databases were searched: Medline, Embase and the Cochrane Library of Registered Controlled Trials. Re-

tried records were screened by 2 reviewers to identify randomised controlled trials of at least 12 weeks duration in which diabetes patients were treated with a fixed dose of sulfonylurea as a monotherapy, added-on to another glucose-lowering medication or compared to a different sulfonylurea dose. HbA1c results were pooled in a random effects meta-analysis. Different sulfonylurea types were examined in subgroup analyses. The effect of trial quality and trial size was investigated in sensitivity analyses.

**Results:** Thirty-two trials were included. In eight trials of sulfonylureas as a monotherapy, HbA1c was on average 1.42% (15 mmol/mol) lower (95% confidence intervals, CI, 1.04–1.80%) with sulfonylurea compared to placebo (Figure). In four trials of sulfonylureas added-on to another oral medication HbA1c was on average 1.62% (18 mmol/mol) CI 1.0 to 2.24%, lower compared to background therapy alone. In seventeen trials of sulfonylurea added-on to insulin treatment HbA1c was on average 0.46% (6 mmol/mol), CI 0.24–0.69% lower than insulin plus placebo. Average insulin dose was 30% lower in the sulfonylurea treated group than the comparator group. Four dose comparison trials did not find any evidence that higher dose sulfonylureas reduce HbA1c more than lower dose sulfonylureas (mean difference 0.05%, CI -0.17 to 0.26). Sensitivity analyses did not show any significant impact of trial quality or size where analyses were possible.

**Conclusion:** Sulfonylureas administered as monotherapy and added-on to oral glucose-lowering medication have been found to lower HbA1c more than a previous systematic review. Sulphonylureas added-on to insulin treatment also lowered HbA1c more than insulin alone and allowed a lower insulin dose. We found no evidence that an increase in sulfonylurea dose increases the reduction in HbA1c. Our results use more trial data than in any previous report and give support to the current recommendations for sulfonylurea treatment.

Supported by: NHS Diabetes

## 789

### HbA<sub>1c</sub> before and after starting treatment with metformin in a large diabetes type 2 cohort

M. Vazquez-Montes, R.J. Stevens, J. Oke, J.K. Aronson, A.J. Farmer;  
Department of Primary Care Health Sciences, University of Oxford, UK.

**Background and aims:** Incentives for improving care in the United Kingdom (UK) Quality Outcomes Framework (QOF) emphasize the use of HbA1c to monitor and titrate treatment of diabetes. Randomised control trials provide evidence that oral glucose reduction treatments lead to improved outcomes in type 2 diabetes. Metformin is the recommended first choice for oral therapy and is the most commonly prescribed glucose lowering agent in the USA and UK. A recent meta-analysis has shown that in metformin monotherapy trials in patients with type 2 diabetes, HbA1c was reduced by 12 mmol/mol. We set out to assess the extent to which initiation of metformin monotherapy in clinical practice is associated with changes in HbA1c levels similar to those observed in trials, by retrospectively analysing routinely recorded primary care data from UK patients with type 2 diabetes.

**Materials and methods:** A cohort of 14,677 patients with type 2 diabetes taking no glucose lowering treatments, who started taking metformin monotherapy, was extracted from the General Practice Research Database (GPRD), a computerised database of longitudinal UK medical records. We plotted

HbA1c over time before and after initiation of metformin. We compared the graphical estimate of the change in HbA1c after starting metformin with estimates from an age-adjusted log-linear random effects model that allowed for dosage of metformin and time after starting metformin.

**Results:** Patients included in the cohort had a mean (sd) age of 63 (11) years at baseline and 57% were male. The BMI (sd) was 29.8 (2.0) kg/m<sup>2</sup> at baseline and 29.9 (2.5) kg/m<sup>2</sup> at the start of treatment. HbA1c increased before metformin treatment, fell abruptly at the start of metformin treatment, and fell gradually thereafter (Figure). Mean daily metformin dose was 1066 mg at initiation, and 1162 mg (n = 5419), 1269 mg (n = 4144) and 1334 mg (n = 3256) after 1, 2, and 3 years respectively. A log-linear random-effects model fitted to the same data indicated an average 12% relative HbA1c reduction at the start of metformin therapy (e.g. from 70.0 to 61.6 mmol/mol). Average change in HbA1c varied with dose by 2.1% (relative change) per additional 500 mg/day of metformin. HbA1c increased on average by 3.6% per year (relative change) before starting metformin and 1.8% per year while on metformin, after allowing for the dosage changes over time.

**Conclusion:** HbA1c fell by about 12% after initiation of metformin comparable to the changes previously reported in a meta-analysis of RCTs. The model shows that in individual patients, HbA1c increased at a slower rate after metformin initiation than with diet alone. However, the figure illustrates that in the cohort, HbA1c fell gradually, probably because of dosage changes and because some patients dropped out of this monotherapy cohort.

### HbA1c in patients with type 2 diabetes before and after starting metformin treatment

## 790

### Can metformin improve survival in severe metformin-associated lactic acidosis?

F. Kajbaf, J.-D. Lalau;  
Endocrinology-Nutrition, University Hospital, Amiens, France.

**Background and aims:** Analysis of the prognostic values of blood pH and lactate and plasma metformin concentrations in severe metformin-associated lactic acidosis may help to resolve the following paradox: metformin provides impressive, beneficial effects but is also associated with life-threatening adverse effects.

**Materials and methods:** On the basis of 869 pharmacovigilance reports on MALA with available data on arterial pH and lactate concentration, plasma metformin concentration and outcome, we selected cases with a pH < 7.0 and a lactate concentration > 10 mmol/L. The outcomes were compared with those described for severe metformin-independent lactic acidosis by Friesecke et al. (Crit. Care 2010).

**Results:** Fifty-six patients met the above-mentioned criteria. The mean pH and lactate concentration were  $6.75 \pm 0.17$  and  $22.9 \pm 6.9$  mmol/L, respectively. The survival rate was 53%, even with pH values as low as 6.5 and lactate concentrations as high as 35.3 mmol/L. Survivors and non-survivors did not differ significantly in terms of the mean arterial pH and lactate concentration. The mean metformin concentration was higher in patients who subsequently died but this difference was due to a very high value in one patient in this group (188 mg/L, N < 1 mg/L). Sepsis and multidrug overdoses were significantly more frequent in the non-survivors ( $p = 0.017$  and  $0.041$ , respectively). There were no survivors in Friesecke's study of metformin-independent lactic acidosis, despite less severe acidosis on average (mean pH: 6.86).

**Conclusion:** Blood pH and lactate did not have prognostic value in 56 cases of severe metformin-associated lactic acidosis. Strikingly, most patients survived despite a mean pH that is incompatible with favorable outcomes under other circumstances.

## 791

### Low-dose pioglitazone improves glycaemic control, whole-body, and adipocyte insulin resistance, and reduces plasma fractalkine, a novel cytokine in type 2 diabetes

D. Tripathy, G. Daniele, Z. Perez-Cadena, A. Chavez, S. Kamath, F. Andreozzi, T.V. Fiorentino, A. Gastaldelli, R. DeFronzo, F. Folli; Diabetes, Medicine, University of Texas Health Science Center, San Antonio, USA.

**Background and aims:** Pioglitazone (PIO) is a potent insulin-sensitizer but its use is limited by weight gain and fluid retention at higher doses (30–45mg/day). Fractalkine (FRK) is a novel chemokine implicated in the pathogenesis of several inflammatory conditions. The aim of the study was to examine the effect of low dose PIO (15mg/day) on metabolic parameters, body weight, and body composition, and on FRK, and whole body and adipose tissue insulin resistance (IR).

**Materials and methods:** 20 type 2 diabetes (T2D) patients (BMI:  $33.5 \pm 1.3$  Kg/m<sup>2</sup>, FPG:  $145 \pm 8$ , Hb1c:  $7.5 \pm 0.3\%$ ) were randomised to receive PIO (15mg/day, n=11) or placebo (PCB, n=9) for 6 months. All subjects participated in an OGTT with insulin and C-peptide measured every 30 min, euglycemic-hyperinsulinemic clamp (80mU/m<sup>2</sup>-min) with measurement of FFA, adipose tissue IR (AT-IR=FFA  $\times$  insulin) and body composition by DXA at 0 and 6-m. Plasma FRK was measured during OGTTs and insulin clamps and at 0, 1, 3, 5 and 6-m.

**Results:** At baseline, subjects in both groups had similar age, BMI, % body fat (BF), HbA<sub>1c</sub>, fasting, and 2-h plasma glucose. PIO led to a greater reduction in fasting PG ( $140 \pm 11$  to  $118 \pm 9.5$  vs  $150 \pm 13$  to  $140 \pm 12$  mg/dL,  $p=0.004$ ), 2-h PG ( $265 \pm 16$  to  $243 \pm 15$  vs  $285 \pm 12$  to  $293 \pm 10$  mg/dL,  $p=0.02$ ), HbA<sub>1c</sub> ( $7.0 \pm 0.2$  to  $6.5 \pm 0.2$  vs  $8.0 \pm 0.5$  to  $7.7 \pm 0.5\%$ ,  $p=0.02$ ), and triglyceride levels ( $190 \pm 16$  to  $135 \pm 17$  vs  $207 \pm 49$  to  $180 \pm 44$  mg/dL,  $p=0.005$ ). PIO improved whole-body insulin sensitivity (IS) ( $3.2 \pm 0.5$  to  $4.1 \pm 0.5$  vs  $3.4 \pm 0.5$  to  $4.5 \pm 0.5$  mg/kg/min,  $p=0.005$ ) and AT-IR ( $p<0.05$ ). At baseline fasting plasma FRK levels were  $33[38]$  pg/ml (median [IQR range]), similar in PIO vs PCB ( $33[30]$  vs  $29[42]$  pg/ml,  $p=ns$ ). After 6-m, FRK decreased in PIO both during fasting state and clamp ( $13[24]$  and  $19[36]$   $p<0.01$  vs 0 m), whereas in PCB group FRK tended to increase during clamp ( $40[34]$ ;  $p=0.06$  vs 0m,  $p<0.003$  vs PIO). During the entire 6 month period FRK significantly increased in PCB ( $51[69]$  pg/ml, mean of 6-m,  $p<0.007$  vs 0 m) but not in PIO ( $40[32]$  pg/ml,  $p=ns$  vs 0 m,  $p<0.02$  vs PCB). At baseline FRK was associated with AT-IR after correcting for BF ( $r=0.75$ ,  $p=0.002$ ), and after 6 m the decrease in FRK was associated with decrease in AT-IR after correcting for changes in BF and improvement in glycemic control ( $r=0.62$ ,  $p=0.05$ ).

**Conclusion:** In conclusion, (i) low-dose PIO therapy improves glycemic control, lipid profile and whole-body and adipose insulin resistance with minimal weight gain, (ii) plasma FRK is associated with AT-IR, and PIO mediated improvement in AT-IR could partly be due to decreased plasma FRK.

## 792

### Initial glucose-lowering therapy and cardiovascular outcomes in type 2 diabetes

I.V. Misnikova, A.V. Dreval, Y.A. Kovaleva; Endocrinology, Moscow Regional Research Clinical Institute, Russian Federation.

**Background and aims:** Association of glucose-lowering therapy with cardiovascular risk still is not clear. Aim of the study was to assess association of oral hypoglycemic monotherapy prescribed after onset of type 2 diabetes (T2D) with all-cause and cardiovascular mortality and risk of myocardial infarction (MI) and stroke.

**Materials and methods:** Retrospective open cohort study. 5-year risk of all-cause and cardiovascular mortality, MI and stroke was estimated in patients with T2D diagnosed in 2004 and treated by single agent sulphonylureas (SU) or metformin. Data of Moscow County Register was used. Total of 5956 subjects were included. Risk of all-cause mortality, myocardial infarction and

stroke was assessed by multivariable Cox regression analysis. Groups were adjusted by age, sex, angina pectoris and previous MI.

**Results:** Compared with metformin SU associated with increased risk of all-cause mortality 2,1 [1,3–3,1]; cardiovascular mortality 2,0 [1,2–3,4], MI 2,6 [1,4–4,7], stroke 2,6 [1,4–4,2]. Risk of all-cause mortality was higher in patients treated with glibenclamide 2,3 [1,5–3,5] and gliquidone 2,3 [1,4–3,8]; risk of MI was higher on glibenclamide 4,8 [1,9–11,8] compared with metformin. Risk of stroke was higher in patients in the glibenclamide group 3,4 [1,7–6,7] and gliquidone group 2,6 [1,2–5,6] then patients treated with metformin. Patients treated with gliclazide had a significantly lower risk of all-cause mortality 0,8 [0,6–0,97] and cardiovascular mortality 0,6 [0,5–0,8] in comparison with glibenclamide group.

**Conclusion:** SU associated with increased 5-year mortality and cardiovascular risk compared with metformin in T2D patients. Risk associated with gliclazide was not statistically significant higher compared with metformin.

### Management of thiazolidinedione induced fluid retention in south Indian patients with type 2 diabetes: effect of spironolactone and amiloride

J. Karalliedde<sup>1</sup>, V. Viswanathan<sup>2</sup>, V. Mohan<sup>3</sup>, P. Tilak<sup>2</sup>, S. Poongothai<sup>3</sup>, S. Agarwal<sup>2</sup>, N. Parthasarathy<sup>3</sup>, G. Subramaniyam<sup>2</sup>, D. Manoharan<sup>2</sup>, C. Chandru<sup>3</sup>, L. Gnudi<sup>1</sup>, G. Viberti<sup>1</sup>;

<sup>1</sup>Diabetes, King's College London, UK, <sup>2</sup>Diabetes, M. V Hospital for Diabetes & Diabetes Research Centre, Chennai, India, <sup>3</sup>Diabetes, Madras Diabetes Research Foundation, Chennai, India.

**Background and aims:** In vitro and animal data suggest that peroxisome proliferator activated receptor  $\gamma$  (PPAR $\gamma$ ) agonists stimulate epithelial sodium channel (ENaC) mediated sodium reabsorption in the distal nephron resulting in plasma volume expansion. The long term management of fluid retention induced by PPAR $\gamma$  agonists such as Pioglitazone or Rosiglitazone (RSG) remains contentious.

**Materials and methods:** We evaluated the effects of Amiloride and Spironolactone, diuretics that act in the distal nephron but affect the ENaC distinctively, on attenuating RSG induced fluid retention in a randomized, placebo controlled study in Chennai, India. We studied 260 T2DM patients who received RSG 4mg bd in addition to background oral agents for 4 weeks. Haematocrit (Hct) was used as a surrogate marker of plasma volume change.

**Results:** Of the 260 patients, 70% (n=180) had evidence of plasma volume expansion defined as an absolute reduction in Hct of  $\geq 1.5\%$  after 4 weeks RSG. These 180 patients (70%M), mean $\pm$ SD, age  $48 \pm 8$  yrs, were randomised to 3 treatments arms; RSG 4mg bd + Spironolactone 50 mg od, RSG 4mg bd + Amiloride 10mg od or RSG 4mg bd + placebo (control group) for 24 weeks. The primary end point was change in Hct at 24 weeks in each diuretic arm versus control group. During the 24 weeks Hct continued to fall significantly in the control group by, mean absolute change (95% CI)  $-1.2(-0.3, -2.2)\%$   $p=0.01$ , and Spironolactone group  $-0.7(-0.1, -1.4)\%$   $p=0.02$ , suggesting continued plasma volume expansion whereas there was no significant change with Amiloride  $[0.0(-0.8, 0.8)\%]$ . After adjustment for baseline values, between group analysis demonstrated that Amiloride was superior to placebo in preventing further Hct fall while Spironolactone was non-significantly different from placebo (Amiloride vs. placebo  $p=0.04$ , Spironolactone vs. placebo  $p=0.41$ ; primary end-point Amiloride was superior to Spironolactone). Haemoglobin fell in placebo and Spironolactone groups as compared to no significant change with Amiloride. HbA<sub>1c</sub> improved similarly in all groups. Blood pressure did not change significantly in all groups.

**Conclusion:** There is a high prevalence of RSG induced fluid retention in South Asian patients with T2DM. In these patients Amiloride, a direct blocker of ENaC, was more effective than Spironolactone preventing protracted/sustained fluid retention

## 794

**Pioglitazone: effect on pancreatic steatosis and beta cell function**I. Lingvay<sup>1</sup>, M. Poduri<sup>1</sup>, E. Szczepaniak<sup>2</sup>, N.M. Maalouf<sup>3</sup>, L. Harrison<sup>1</sup>, L.S. Szczepaniak<sup>2</sup><sup>1</sup>Internal Medicine/Endocrinology, University of Texas Southwestern Medical Center, Dallas, <sup>2</sup>The Heart Institute, Cedars-Sinai Medical Center, Los Angeles, <sup>3</sup>Internal Medicine, University of Texas Southwestern Medical Center, Dallas, USA.

**Background and aims:** An excessive accumulation of triglycerides (TG) within the muscles and liver leads to insulin resistance while deposition in the pancreas may cause beta-cell dysfunction, a theory known as lipotoxicity. While pioglitazone, a PPAR gamma agonist, is known to increase insulin sensitivity and preserve insulin secretion it is unknown if it does this by decreasing ectopic TGs. This study evaluates the effect of pioglitazone on pancreatic TG content in correlation with insulin secretion and sensitivity.

**Material and methods:** We conducted a prospective, randomized, double-blind, placebo controlled trial to evaluate the effect of treatment with pioglitazone 45 mg daily for 6 months in adults with pancreatic TG content >4%. Eligible volunteers had the following measurements at baseline and 6-month follow-up: HbA<sub>1c</sub>, fasting lipid profile, beta-cell function and insulin sensitivity by frequently sampled intravenous glucose tolerance test (FSIVGTT), liver and pancreatic TG content by magnetic resonance spectroscopy (MRS), subcutaneous and visceral fat mass by MRI, and total body fat/lean mass by densitometry. Pancreatic TG measurement in 4 participants (1 placebo and 3 pioglitazone) had to be excluded due to visceral fat contamination. Data are median+/-interquartile range; between group comparisons were carried out using Wilcoxon t-test.

**Results:** Nineteen volunteers (9 placebo and 10 pioglitazone) completed 6-months of follow-up. Baseline characteristics as well as results are shown in Table 1. Pancreatic and hepatic TG content significantly decreased (p=0.04 and p=0.01, respectively). Insulin sensitivity improved significantly and there was a commensurate decrease in insulin secretion, therefore the disposition index remained unchanged. Total body fat was significantly increased in the pioglitazone treated group.

**Conclusion:** Pioglitazone effectively removes fat from ectopic sites, including the pancreas. In these preliminary results, insulin secretion (adjusted for insulin sensitivity) did not change. Longer intervention and follow-up are in progress to evaluate whether a reduction in pancreatic fat will ultimately translate to improvement of beta-cell function.

**The relationship between BMI and glycaemic control after monotherapy with metformin XR in Chinese patients with type 2 diabetes mellitus**H. Li<sup>1</sup>, L. Ji<sup>2</sup>, Z. Zhu<sup>3</sup>, J. Newman<sup>4</sup><sup>1</sup>Global Clinical Research, Bristol Myers Squibb, Shanghai, China,<sup>2</sup>Endocrinology and Metabolism, People's Hospital of Peking University, China, <sup>3</sup>Global Clinical Research, Bristol Myers Squibb, Princeton, USA,<sup>4</sup>Research and Development, Bristol Myers Squibb, Melbourne, Australia.

**Background and aims:** Recent global studies report the safety and efficacy of monotherapy with metformin XR in normal-weight T2DM patients; however, this has not been investigated in Chinese T2DM patients.

**Materials and methods:** This open-label, 3-arm, multicenter trial in newly diagnosed Chinese T2DM patients was conducted in 20 sites in China. A total of 371 patients were enrolled into 3 groups according to their baseline BMI (normal weight, 24 kg/m<sup>2</sup> < BMI ≤ 18.5 kg/m<sup>2</sup> BMI, n=125; overweight, 28 kg/m<sup>2</sup> < BMI ≤ 24 kg/m<sup>2</sup>, n=122; obese, BMI ≥ 28 kg/m<sup>2</sup>, n=124) as defined in the 2007 Chinese guidelines. The primary efficacy endpoint of this study was the change from baseline in HbA<sub>1c</sub> after a 16-week oral administration of metformin XR. Secondary endpoints were the change from baseline in fasting plasma glucose (FPG), the relative changes from baseline in fasting lipids (TC, LDL-C, HDL-C, and TG), and changes from baseline in CRP, PAI-1, and adiponectin. Patients were treated with an oral dose of metformin XR for 16 wks. The initial dose was 500 mg/d; up-titrated by increments of 500 mg/wk to 1500 mg/d, unless intolerance or hypoglycaemia occurred. A maximum dose of 2000 mg/d metformin XR was permitted from Weeks 4-16.

**Results:** Metformin XR is safe and efficacious in the treatment of normal weight as well as overweight and obese Chinese patients with newly diagnosed T2DM, achieving a mean reduction HbA<sub>1c</sub> of 1.80%. Differences between the normal weight and obese groups suggest that the effect of BMI on the response to metformin is clinically relevant. Improvement in FPG was also demonstrated, with a mean reduction of 2.097 mmol/L in FPG from baseline to final study visit. Fasting lipid levels improved in all groups (↓TC of 0.195 mmol/L; ↓LDL-C of 0.211 mmol/L, ↑HDL-C of 0.037 mmol/L; ↑adiponectin of 4.865 ng/mL).

**Conclusion:** BMI did not impact on the efficacy of metformin XR in Chinese patients with newly diagnosed type 2 diabetes.

**Adding glimepiride to insulin+metformin in patients with type 2 diabetes of more than ten years duration-a randomised, double-blind, placebo-controlled cross-over study**

Å. Nybäck-Nakell, P.-E. Lins, U. Adamson, L. Landstedt-Hallin;

Department of Clinical Sciences, Division of Medicine, Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** To investigate the effect on glycaemic control by adding glimepiride to ongoing treatment with metformin and insulin in patients with type 2 diabetes with more than 10 years duration.

**Materials and methods:** Patients with a diagnosis of type 2 diabetes for at least 10 years, treated with metformin and insulin, but no sulfonylurea, for at least one year prior to the study were included. Glimepiride 4 mg OD or placebo was added, in a randomized order, to ongoing therapy with metformin and insulin. Each treatment period was three months long with a wash-out of six weeks. All kinds of insulin regimens were allowed and were not changed during the study but the insulin doses were reduced if the patient had a fP-glucose less than 5.0 mmol/l or had symptomatic hypoglycaemia. At the end of each treatment period continuous glucose monitoring (CGMS) was performed during 72 hours to monitor nocturnal glycaemia. HbA<sub>1c</sub>, fasting C-peptide as well as postprandial C-peptide after a standardized breakfast were measured. The primary outcome was HbA<sub>1c</sub>.

**Results:** 43 patients, median age 66 years (46-74), with a diabetes duration of 16 years (10-30), BMI 30 kg/m<sup>2</sup> (25-37) and mean HbA<sub>1c</sub> (Mono-S) 7.1±0.7 % (IFCC 64 mmol/mol) were randomized. At baseline fP-glucose was 8.9±2.7 mmol/l. The fasting C-peptide was 0.69 (0.09-2.10) nmol/l which increased after breakfast to 1.50 (0.30-2.70) nmol/l. The total insulin dose used was 0.50 (range 0.08 to 2.68) U/kg. During the placebo period no change was observed in HbA<sub>1c</sub> while a decrease, from 7.0% to 6.4% (p<0.001), was observed with glimepiride. There was no effect of randomization sequence. The insulin dose had to be reduced in 23 patients by 29 % in median (range 2.1-100%). The ratio between C-peptide/glucose increased significantly with glimepiride, in the fasting state from 0.087 to 0.131 (p<0.001) and postprandially from 0.128 to 0.184 (p<0.001) respectively. A stepwise multiple regression analysis of possible predictive factors for response to glimepiride (age, weight, diabetes duration, postprandial C-peptide/glucose ratio, insulin dose U/kg) revealed that higher age and insulin dose/kg were associated with a smaller decrease in HbA<sub>1c</sub>. Twenty patients (67%) were responders to glimepiride when we defined response as a decrease in HbA<sub>1c</sub> of ≥0.5% or a dose reduction of insulin ≥ 20%. No severe hypoglycaemic event was observed in the study. 22 patients reported hypoglycaemic episodes during daytime, of these 67%

occurred during the glimepiride period. When analysing CGMS recordings between midnight and 6 am, hypoglycaemia was defined as two consecutive measurements <3.1 mmol/l. Time spent at these levels were calculated. Five patients had values <3.1 mmol/l during the end of the placebo period. At the end of glimepiride treatment 16 patients had values <3.1 mmol/l and the median time spent at these levels was 55 min (5–280).

**Conclusion:** Even after more than ten years of known diabetes duration addition of glimepiride to insulin and metformin therapy can be effective in lowering HbA<sub>1c</sub> and/or reducing the need for exogenous insulin.

#### Real-world characteristics of patients with type 2 diabetes initiating insulin glargine plus exenatide or insulin glargine plus liraglutide

A. DiGenio<sup>1</sup>, Z. Ling<sup>1</sup>, K.L. Davis<sup>2</sup>, J.L. Meyers<sup>2</sup>, M.R. Dalal<sup>1</sup>;

<sup>1</sup>Sanofi-Aventis U.S., Bridgewater, <sup>2</sup>RTI Health Solutions, Research Triangle Park, USA.

**Background and aims:** Real-world data on patients initiating basal insulin therapy plus glucagon-like peptide-1 (GLP-1) analogs are limited. This study aimed to document real-world baseline characteristics and clinical endpoints of type 2 diabetes mellitus (T2DM) patients receiving treatment with insulin glargine plus liraglutide (GLA + LIR) or insulin glargine plus exenatide (GLA + EXE).

**Materials and methods:** Using the General Electric Centricity database of electronic medical records (EMR), a retrospective analysis was conducted of T2DM patients ≥ 18 years old who initiated a basal insulin between January 2005 and January 2012 with subsequent or simultaneous initiation of exenatide or liraglutide as add-on GLP-1 analog therapy. Patients had ≥ 6 months EMR activity prior to and ≥ 3 months EMR activity after index date, defined as the first date of combined prescription of both drugs. Primary study endpoints included HbA<sub>1c</sub> levels and body weight and were analyzed descriptively in unmatched treatment groups. Analysis of hypoglycemia rates and gastrointestinal related events and analysis of matched cohorts will be conducted as next steps.

**Results:** At baseline, GLA + LIR patients (N = 149) and GLA + EXE patients (N = 468) had similar age (mean [SD], 57.5 [11.4] and 56.3 [11.6] years). A similar proportion of patients in both groups were male (GLA + LIR: 49.0%, GLA + EXE: 45.9%). GLA + LIR and GLA + EXE patients had similar HbA<sub>1c</sub> levels (8.6% and 8.6%) and body weight (109.7 kg and 110.4 kg) at baseline. The Charlson Comorbidity Index score was 0.9 and 0.8 in GLA + LIR and GLA + EXE patients, respectively. At 6 months and 1 year after the index date, GLA + LIR patients showed a significant reduction in HbA<sub>1c</sub> levels from baseline of −0.66% (*P* < 0.0001) and −0.50% (*P* = 0.005). Body weight in the GLA + LIR group was significantly decreased at 6 months (−2.12 kg, *P* < 0.0001), but not significantly at 1 year after index date (−1.46 kg, *P* = 0.22). GLA + EXE patients also showed significant reductions in HbA<sub>1c</sub> levels and body weight. HbA<sub>1c</sub> levels were −0.50% (*P* < 0.0001) and −0.44% (*P* < 0.0001) lower, while body weight was decreased by −1.98 kg (*P* < 0.0001) and −2.19 kg (*P* < 0.0001) at 6 months and 1 year, respectively.

**Conclusion:** This study demonstrates that, when added to insulin glargine, the GLP-1 agonists exenatide and liraglutide can be associated with reductions in HbA<sub>1c</sub> levels and body weight in T2DM patients in a real-world setting. Matched analysis needs to be considered to explore whether the differences in outcomes between both treatment groups are significant after key confounders are controlled.

Table: Demographic and clinical characteristics of GLA + LIR and GLA + EXE patients

Characteristic	GLA + LIR (n = 149)	GLA + EXE (n = 468)
Mean (sd) age, years	57.5 (11.4)	56.3 (11.6)

## 798

**Safety and tolerability of GLP-1 receptor agonists in patients with type 2 diabetes in comparator-controlled DURATION trials**

L. MacConell, S. Chen, K. Gurney, J. Malloy, H. Zhang, M. Zhou, O. Kolterman;  
Amylin Pharmaceuticals, Inc., San Diego, USA.

**Background and aims:** Injectable GLP-1 receptor agonists (RA) provide a novel mechanism for the treatment of type 2 diabetes mellitus (T2DM). The objective of this post hoc analysis was to characterise and compare the safety and tolerability of exenatide once weekly (EQW) vs exenatide twice daily (EBID) or liraglutide in separate comparator-controlled studies.

**Materials and methods:** Individual patient data were analyzed from the ITT populations of the 30 and 26-week DURATION (DUR)-1 and DUR-5 trials that compared EQW vs EBID (n=545) and DUR-6 trial that compared EQW vs liraglutide (n=911). Study designs and patient characteristics were generally the same across trials with the exception of exclusion of drug-naïve patients in DUR-6. The EQW vs EBID trials were pooled and comparisons between treatments were considered separately. Incidence of treatment-emergent adverse events (AEs), exposure-adjusted incidence, and risk difference and its 95% CI were calculated. Duration and recurrence of AEs over time were analysed for gastrointestinal (GI)-related and injection-site-related AEs.

**Results:** Incidences of serious AEs did not differ between treatments for any comparison (Table). Discontinuations due to AEs were similar between treatments in the EQW vs. EBID comparison and higher with liraglutide compared to EQW. The most frequent AEs in any group were gastrointestinal in nature, which were generally mild and mainly occurred upon initiation of treatment with incidences decreasing over time. Incidences of GI-related AEs at treatment initiation and overall were lower with EQW compared to EBID and with EQW compared to liraglutide. Discontinuations due to GI-related AEs were infrequent in all groups, but occurred more frequently with liraglutide than with EQW. Injection-site-related AEs were highest with EQW compared to all other groups, but were generally mild and abated over time. Only 2 patients discontinued due to injection-site-related AEs (both with EQW, including nodule and pruritus). Overall, the incidence of minor hypoglycaemia was low across all groups and occurred more frequently with concomitant SU use. There was no major hypoglycaemia in any group. Pancreatitis, pancreatic cancer, thyroid cancer, and renal-related AEs were rarely reported and incidence was similar between groups.

**Conclusion:** This post hoc analysis found that the overall safety and tolerability profile of the GLP-1 RAs was similar across treatments, with significantly improved gastrointestinal tolerability observed in patients treated with EQW.

Event, n (%)	EQW vs EBID (Pooled, DUR-1 and -5)			EQW vs LIRA (DUR-6)		
	EQW N=277	EBID N=268	Diff (95% CI)	EQW N=461	LIRA N=450	Diff (95% CI)
Serious AEs	11 (4.0)	10 (3.7)	0.2 (-3.0, 3.5)	13 (2.8)	7 (1.6)	1.3 (-0.6, 3.2)

Abbreviations: EQW, exenatide once weekly; EBID, exenatide twice weekly; Diff, difference; LIRA, liraglutide; GI, gastrointestinal; AE, adverse event; inj, injection; DUR, DURATION; SU, sulfonylurea. Treatment differences (Diff [95% CI]) are differences in percentages of patients for comparison of pooled EQW vs pooled EBID or EQW vs liraglutide. Hypoglycaemia includes minor and major events. \*Inj-site-related AEs, specific = injection-site rash, pruritus, erythema, and urticaria.

Clinical trial registration number: NCT00308139, NCT00637273, NCT01029886

## 799

**Efficacy and safety of exenatide once weekly in patients with type 2 diabetes mellitus: a post hoc analysis of pooled data from the DURATION clinical trials**

J. Ruggles, M. Grimm, J. Han, C. Weaver, P. Griffin, C. Schulteis, H. Dong, D. Maggs, J. Malloy;  
Amylin Pharmaceuticals, Inc., San Diego, USA.

**Background and aims:** Exenatide is a glucagon-like peptide-1 receptor agonist that has been demonstrated to improve glycaemic control and reduce body weight with low risk of hypoglycaemia in patients with type 2 diabetes (T2DM). The efficacy and safety of exenatide once weekly (EQW), an ex-

tended-release formulation of exenatide, has been assessed in 6 randomised, comparator-controlled, 24- to 30-wk trials (DURATION-1 through -6). In this post hoc analysis, data from patients treated with EQW in these trials were pooled to assess efficacy and safety across a large population over approximately 6 months.

**Materials and methods:** Data from 1379 intent-to-treat patients treated with EQW were pooled. Mean changes from baseline to endpoint (24-30 wk) in HbA<sub>1c</sub>, fasting blood glucose (FBG), body weight, and cardiovascular (CV) risk factors (blood pressure [BP] and fasting lipids) were assessed. Changes in HbA<sub>1c</sub> were also analysed by baseline HbA<sub>1c</sub> (<9% or ≥9%). The percentage of patients achieving HbA<sub>1c</sub> goals without weight gain and hypoglycaemia was determined.

**Results:** At baseline, ITT patients were 55% male, with a mean±SD age of 55±10 y, HbA<sub>1c</sub> of 8.4±1.1%, BMI of 32.5±5.4 kg/m<sup>2</sup>, FBG of 9.6±2.7 mmol/L, and duration of T2DM of 7±6 y. Improvements in glycaemic control were observed following 24-30 wk of treatment with EQW (LS mean change from baseline±SE: HbA<sub>1c</sub>, 1.4±0.0%; FBG, 2.0±0.1 mmol/L), with significant reductions in HbA<sub>1c</sub> evident by week 4 of treatment. Patients with baseline HbA<sub>1c</sub> <9% achieved an LS mean reduction±SE of -1.1±0.0%, whereas patients with baseline HbA<sub>1c</sub> ≥9% achieved a larger reduction of 2.2±0.1%. At endpoint, 59% of patients achieved HbA<sub>1c</sub> <7%, and 39% achieved HbA<sub>1c</sub> ≤6.5%. EQW treatment resulted in significant weight loss at endpoint (LS mean change±SE: 2.5±0.1 kg), with 76% of patients losing weight; 70% had reductions in both weight and HbA<sub>1c</sub>. Modest but statistically significant improvements were observed in CV risk factors (LS mean change±SE: systolic BP, 2.8±0.4 mmHg; diastolic BP, 0.8±0.2 mmHg; total cholesterol, 0.17±0.02 mmol/L; LDL, 0.10±0.02 mmol/L; triglycerides [geometric LS mean % change±SE, median], 6±1%, 0.09 mmol/L). EQW was generally well tolerated, with a low incidence of adverse events (AEs) leading to withdrawal (4%) and serious AEs (3%). The most common AEs were nausea (16%), diarrhoea (11%), nasopharyngitis (8%), headache (8%), injection-site nodule (7%), vomiting (6%), constipation (6%), and injection-site pruritus (5%). New events of nausea and vomiting decreased over time, and seldom led to withdrawal (0.4% and 0.1%, respectively). No major hypoglycaemia occurred; minor hypoglycaemia occurred primarily in patients using a sulphonylurea (SU; 16%) and occurred in few patients not using an SU (3%). Overall, 45% of patients achieved a clinically relevant composite goal at endpoint of HbA<sub>1c</sub> <7% with no weight gain and no hypoglycaemia, and 31% achieved this goal with HbA<sub>1c</sub> ≤6.5%.

**Conclusion:** Results from this post hoc analysis of >1300 patients demonstrated that exenatide administered once weekly over 24-30 wk provided improvements in glycaemic control, weight loss, and CV risk factors, with low risk of hypoglycaemia. Consistent with the known safety profile, EQW therapy was generally well tolerated, with gastrointestinal AEs occurring most frequently and seldom leading to treatment discontinuation.

Clinical Trial Registration Number: NCT00308139, NCT00637273, NCT00641056, NCT00676338, NCT00877890, NCT01029886

**Is insulin the most effective injectable HbA<sub>1c</sub>-lowering therapy?**

M. Diamant<sup>1</sup>, A. Peters<sup>2</sup>, D. Russell-Jones<sup>3</sup>, S. Furber<sup>4</sup>, M. Donsmark<sup>4</sup>, J. Han<sup>5</sup>, L. MacConell<sup>1</sup>, D. Maggs<sup>5</sup>, J. Buse<sup>6</sup>;

<sup>1</sup>Endocrinology / Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands, <sup>2</sup>University of Southern California, Los Angeles, USA, <sup>3</sup>Royal Surrey County Hospital, Guildford, UK, <sup>4</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>5</sup>Amylin Pharmaceuticals, Inc, San Diego, USA, <sup>6</sup>University of North Carolina School of Medicine, Chapel Hill, USA.

**Background and aims:** In recent deliberations, it was concluded that only insulin was deserving of a 'highest' designation in efficacy of HbA<sub>1c</sub> reduction among antihyperglycaemic agents. Basal insulins have been traditionally used to treat patients with serious hyperglycaemia. However, recent data on the GLP-1 receptor agonists (GLP-1RA) exenatide once weekly (ExOW) and liraglutide (LIRA) once daily (QD) suggested superior efficacy to insulin glargine (GLAR).

**Materials and methods:** To assess the effectiveness of GLP-1RA and basal insulin in patients with varying degrees of hyperglycaemia, we conducted analyses of the LEAD-5 and DURATION-3 data to examine HbA<sub>1c</sub>, fasting plasma glucose (FPG), weight and insulin dose by quartiles (Q) of baseline HbA<sub>1c</sub>. These were open-label comparisons respectively of LIRA 1.8 mg QD and ExOW 2 mg versus GLAR QD titrated to FPG <5.5 mmol/L for 26 weeks.

**Results:** The table presents mean values of HbA<sub>1c</sub> for Q1-Q4 at baseline and the change at 26 week for LIRA and ExOW versus GLAR. The change in

HbA<sub>1c</sub> was equivalent or greater at all quartiles of HbA<sub>1c</sub> for both ExOW and LIRA compared to GLAR. Further analyses will be presented on FPG and insulin dose/titration suggesting reasonable insulin titration as well as on change in body weight suggesting additional extra-glycaemic benefits of long-acting GLP-1RA.

**Conclusion:** Clearly, these data demonstrated that in a clinical trial setting, where insulin use can be optimised, GLP-1RA were similar, if not superior in efficacy to basal insulin for HbA<sub>1c</sub> reduction for patients with type 2 diabetes failing 1–2 oral antihyperglycaemic agents.

### Liraglutide is effective across a range of obese body mass indices; findings from the Association of British Clinical Diabetologists (ABCD) nationwide liraglutide audit

R.E.J. Ryder, P. Sen-Gupta, K.Y. Thong, ABCD nationwide liraglutide audit contributors;  
City Hospital, Birmingham, UK.

**Introduction:** It is uncertain whether GLP-1 receptor agonist treatment is effective across a range of body mass indices (BMI). We assessed the treatment response to liraglutide stratified according to patients' pre-treatment BMI.

**Methods:** Data was obtained from the ABCD nationwide liraglutide audit. The audit collected anonymised, clinical data of patients routinely treated with liraglutide in clinical practice. Diabetes centres across UK were invited to participate. Data on reduction of HbA<sub>1c</sub>, weight, and weight as a percentage of initial body weight was assessed at three months (± 6 weeks) of liraglutide treatment. These results were compared among patients divided according to six BMI groups of 25–29.9 kg/m<sup>2</sup>, 30–34.9 kg/m<sup>2</sup>, 35–39.9 kg/m<sup>2</sup>, 40–44.9 kg/m<sup>2</sup>, 45–49.9 kg/m<sup>2</sup> and 50–54.9 kg/m<sup>2</sup>. We excluded patients who switched from exenatide to liraglutide therapy, who used liraglutide 1.8 mg rather than the 1.2 mg dose, who used insulin, who had no BMI data, who had BMI <25 kg/m<sup>2</sup> or >55 kg/m<sup>2</sup>, whose follow up data was outside the specified time frame, or who were lost to follow-up.

**Results:** 77 centres contributed data on 4129 patients with mean (SD) HbA<sub>1c</sub> of 9.4% (1.7) and BMI of 38.8 kg/m<sup>2</sup> (7.3). After exclusions, there were 634 and 588 HbA<sub>1c</sub> and weight data for comparisons among the six BMI groups. No difference in HbA<sub>1c</sub> reduction was seen between BMI groups either before (p=0.929) or after adjustment for factors such as baseline HbA<sub>1c</sub> and ethnicity (p=0.894) (Table). Mean HbA<sub>1c</sub> reductions were between -1.1% to -1.4%. In contrast, weight loss increased with greater BMI (p=0.010), ranging from -1.8 kg to -4.4 kg. However, weight loss as a percentage of initial body weight was similar across BMI groups (ranging from -2.2% to -3.1% initial body weight).

**Conclusion:** The use of liraglutide in the UK as reported in the nationwide audit was common among patients with significant obesity. This is likely due to national guidelines that only support the use of GLP-1 receptor agonists in heavier patients. Liraglutide was effective across a range of obese body mass indices among non-insulin-treated patients with type 2 diabetes. Table: HbA<sub>1c</sub> and weight reduction at three months after liraglutide 1.2 mg treatment across patients with BMI 25 to 55 kg/m<sup>2</sup>.

### Liraglutide and metformin combination therapy: clinical benefits associated with early use of liraglutide in type 2 diabetes and with switching a sulphonylurea to liraglutide

S.C. Bain<sup>1</sup>, J. Seufert<sup>2</sup>, A.B. Thomsen<sup>3</sup>, S. Furber<sup>3</sup>, D. D'Alessio<sup>4</sup>;

<sup>1</sup>Department of Medicine, Abertawe Bro Morgannwg University NHS Trust, Swansea, UK, <sup>2</sup>University Hospital of Freiburg, Germany, <sup>3</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>4</sup>University of Cincinnati, USA.

**Background and aims:** When first-line metformin (met) becomes insufficient in type 2 diabetes, there is no general consensus on how to advance treatment. The aim of this post-hoc analysis was to compare the clinical benefits associated with add-on liraglutide 1.8 mg treatment in patients previously receiving met monotherapy (met-add-on group) vs substitution of a sulphonylurea (SU) with liraglutide 1.8 mg in patients previously receiving met + SU combination therapy (SU-switch group).

**Materials and methods:** Data were obtained from a large clinical trial (n=988) in which patients receiving met monotherapy or met + SU (SU dose at ≤ half of the maximum approved dose) had their therapy changed to met + liraglutide 1.8 mg. Liraglutide was initiated at 0.6 mg/day and incremented by 0.6 mg/day on a weekly basis to the final 1.8 mg/day dose.

**Results:** Duration of diabetes was significantly longer in the SU-switch patients compared with the met-add-on group (Table). Among patients who completed 12 weeks of treatment with met + liraglutide 1.8 mg, the SU-switch group lost more weight compared with the met-add-on group. Completers in the met-add-on group had a greater reduction in HbA<sub>1c</sub> compared with the SU-switch group.

**Conclusion:** The greater reduction in weight in the SU-switch group vs the met-add-on group is likely due to the termination of SU treatment. Reductions in HbA<sub>1c</sub> may be positively influenced by the slightly higher baseline HbA<sub>1c</sub> in the met-add-on group and negatively influenced by termination of SU in the switch group, although the latter is a reflection of clinical practice. While liraglutide improved glycaemic control in both subgroups, these data suggest that the effect of liraglutide may depend on the duration of diabetes and prior treatments. These factors should be considered when making treatment decisions and designing trials with liraglutide.

## 803

### Does liraglutide confer greater glycaemic benefits than exenatide when used with oral agents versus insulin in clinical practice?

Q. Zhang<sup>1</sup>, P. Levin<sup>2</sup>, E. Chou<sup>1</sup>

<sup>1</sup>R&D, Sanofi, Bridgewater, <sup>2</sup>Model Clinical Research, Baltimore, USA.

**Background and aims:** In randomized trials, adding LIRA (liraglutide) versus EXEN (exenatide) to oral agents (OADs) result in greater improvements in A1C and fasting plasma glucose but not in prandial glucose excursions. This study evaluated real world glycemic effects of LIRA vs EXEN when adding to oral agents or insulin.

**Materials and methods:** Patients with A1C  $\geq 7\%$  were identified from IM-PACT™ claims database (Jan 2009-Dec 2010) and evaluated according to the intention to treat A1C response, defined as a  $\geq 0.8\%$  reduction plus any A1C value  $\leq 7\%$  within 6 months after initiation of LIRA or EXEN.

**Results:** The mean age of patients was 52 years for both LIRA (n=878) and EXEN (n=1,638). Previous use of OAD only was 66 vs 71% and majority of insulin therapy was basal, 21 vs 18% in LIRA vs EXEN respectively. Baseline A1C (8.7% vs 8.9%) and comorbidity burden (Charlson comorbidity score: 1.68 vs 1.85) were comparable in LIRA vs EXEN. Six-month A1C response rate was 26% in Lira and 15% in EXEN ( $P<0.01$ ), with a hazard ratio (HR) of 1.76 (95% CI: 1.47-2.11) after adjustment of baseline A1C, concomitant medications, comorbidity, and other baseline characteristics. GLP-1 medication adherence was also used as a covariate and strongly associated with A1C response (HR=3.58; 2.54-5.04). Propensity matched (1:1) response estimates remained unchanged with 26% in LIRA vs 16% in EXEN (Odds Ratio=1.82; 1.42-2.33). Stratified by OAD vs basal insulin therapy, response rate was 28 vs 17% in OAD only (OR=1.95; 1.45-2.61), and 13 vs 14% in basal insulin (OR=0.89; 0.46-1.73) for LIRA vs EXEN.

**Conclusion:** A1C benefit with LIRA shown in clinical trials is confined only to patients on OADs in this real world database study. When adding to insulin, the A1C response rate in LIRA declined more than 50% relative to that in the combination with OADs, showing no difference from the response rate in EXEN. This suggests the clinical need for an alternative GLP-1 therapy with a complementary mode of glucose lowering action to basal insulin to optimize glycemic control.

### Addition of fixed-dose exenatide to insulin glargine therapy improved glycaemic control without increasing hypoglycaemia or weight gain across a range of insulin titration

M. Wintle<sup>1</sup>, R. Penczek<sup>1</sup>, J. Han<sup>1</sup>, S. Miller<sup>1</sup>, J. Buse<sup>2</sup>

<sup>1</sup>Amylin Pharmaceuticals, Inc., San Diego, <sup>2</sup>University of North Carolina, Chapel Hill, USA.

**Background and aims:** In a recent 30-week, randomised, controlled, phase 3 study in patients with type 2 diabetes, the addition of fixed-dose, mealtime exenatide to titrated insulin glargine significantly improved glycaemic control without additional hypoglycaemia or weight gain when compared to titrated insulin glargine and placebo. To better understand the interaction between fixed exenatide dosing and insulin titration, a post hoc analysis was performed to examine these effects in relation to the variable degree of insulin titration that actually occurred as a result of the insulin titration algorithm specified in the protocol.

**Materials and methods:** Study subjects (age  $59\pm 9$  y, HbA<sub>1c</sub>  $8.4\pm 0.9\%$ , weight  $94\pm 21$  kg, duration of diabetes  $12\pm 7$  y, mean $\pm$ SD) on pre-existing ( $\geq 3$  mo) insulin glargine were randomized to placebo (n=123) or exenatide twice daily (n=138; 5 mcg for 4 weeks then 10 mcg for the remainder of the study). Insulin glargine was titrated according to the Treat-to-Target algorithm with the goal of achieving fasting plasma glucose (FPG)  $<5.6$  mmol/L (100 mg/dL). Subjects from both treatments were pooled and divided into 3 tertiles (T1, T2, T3) according to the change in insulin dose between baseline and endpoint. Treatments were compared for effects on FPG, HbA<sub>1c</sub>, weight, and incidence of hypoglycaemia within each insulin titration tertile.

**Results:** Mean insulin titration in each tertile ranged from modest reductions in T1 to substantial increases in T3 (Table). Greater improvements in HbA<sub>1c</sub> were demonstrated in all titration tertiles with the addition of exenatide to insulin glargine compared to placebo plus insulin glargine. Between-treatment differences were statistically significant in T2 and T3 for HbA<sub>1c</sub> reduction (Table) and percentage of subjects achieving HbA<sub>1c</sub>  $<7\%$  (exenatide vs placebo: T1, 44% vs 29%; T2, 65% vs 26%; T3, 54% vs 29%). Percentage of subjects reaching HbA<sub>1c</sub>  $\leq 6.5\%$  was significantly greater with exenatide in all 3 tertiles (T1, 33% vs 9%; T2, 52% vs 10%; T3, 36% vs 16%). Incidence of hypoglycaemia was lower with exenatide in each tertile of insulin titration (Table). Adjunctive exenatide was associated with statistically significant weight loss in T1 and T2 and exenatide significantly inhibited the weight gain associated with the insulin increase in T3 ( $-0.09$  kg vs  $1.96$  kg). A linear regression analysis of insulin titration vs weight change by treatment revealed that, on average, weight gain occurred with the addition of  $\geq 5$  U of insulin in placebo-treated subjects. In contrast, subjects receiving adjunctive exenatide could add up to 33 U without experiencing weight gain or additional hypoglycaemia.

**Conclusion:** The addition of fixed-dose, mealtime exenatide to systematically titrated insulin glargine significantly improved glucose control without increasing the risk of hypoglycaemia and with mitigation of insulin-induced weight gain.

# Liraglutide in paediatric subjects with type 2 diabetes: a population pharmacokinetic (PK) analysis and comparison to adult subjects

K.C. Petri<sup>1</sup>, L. Jacobsen<sup>1</sup>, S. Ingwersen<sup>1</sup>, D. Klein<sup>2</sup>;

<sup>1</sup>Novo Nordisk, Søborg, Denmark, <sup>2</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, USA.

**Background and aims:** The prevalence of type 2 diabetes (T2D) in the paediatric population is increasing. Only metformin and insulin are approved for the treatment of paediatric patients. Thus, there is a medical need for more treatment options. This analysis investigated the population PK of the once-daily human GLP-1 analogue liraglutide in paediatric subjects (10–17 yrs) with T2D and compared the results to those seen in previous liraglutide PK trials in adults.

**Materials and methods:** A 1-compartment model with 1<sup>st</sup>-order absorption and elimination was used to estimate clearance (CL/F) and volume of distribution (V/F) for each liraglutide dose level in a pooled data set of 3 trials (1 in children, 2 in adults). AUC<sub>0–24h</sub><sup>ss</sup> derived from CL/F and dose was used to investigate dose proportionality in the paediatric trial. A covariate analysis investigated the effects of dose, body weight, gender and age category (paediatric/adult) on liraglutide exposure. Data sources: Demographics and PK data from 3 trials including subjects with T2D. Trial 1: 13 paediatric subjects (8 female), 10–17 yrs with baseline body weight 57–214 kg; frequently sampled plasma samples (0–13 h, 0–24 h for final dose) were collected following once daily liraglutide doses (with sequential weekly increases) of 0.3, 0.6, 1.2, and 1.8 mg. Trial 2: 12 adults (6 female) with body weight 72–104 kg. Trial 3: 32 adults (9 female) with body weight 58–140 kg. Frequently sampled plasma samples (0–60 h, 0–24 h, respectively) from Trials 2 and 3 were collected at 1.8 mg steady state.

**Results:** PK data indicated dose proportionality for the model-derived AUC<sub>0–24h</sub><sup>ss</sup> in the dose range 0.3–1.8 mg in the paediatric subjects with T2D (slope: 1.05 (95%CI 0.96–1.15)). Consistent with findings with sparse PK data from adult phase 3 trials, body weight and gender were significant covariates for liraglutide exposure in the paediatric population. AUC<sub>0–24h</sub><sup>ss</sup> decreased with increasing body weight and was lower for males than for females. Geometric mean AUC<sub>0–24h</sub><sup>ss</sup> was 63% (44–84% CI) higher at the lowest observed body weight (53 kg) and 56% (46–64% CI) lower at the highest observed body weight (216 kg) compared to the exposure at the median body weight of 90 kg. Males had 31% (17–42%) lower exposure (AUC<sub>0–24h</sub><sup>ss</sup>) than females. Exposure in paediatric subjects was not significantly different from adults. The CL/F estimates (Fig), and thus exposure, for the paediatric subjects with T2D were similar to those in the adult trials. The differences between the adult Trials 2 and 3 were partly due to differences in body weight and gender distribution.

**Conclusion:** Based on this population PK analysis, the same liraglutide dose regimen as used in adults, is predicted to achieve the same range of exposures in the paediatric population (10–17 yrs, 57–214 kg) as found clinically effective in adults. A larger scale trial is planned to further investigate the safety, tolerability and efficacy of liraglutide in the paediatric population with T2D.

Geometric mean (95% CI) of post hoc estimated clearance (CL/F) for liraglutide 1.8 mg in Trial 1 (paediatric T2D subjects) and Trials 2 and 3 (adult T2D subjects).

# Identifying predictors of response to liraglutide in type 2 diabetes using recursive partitioning analysis

R. Ratner<sup>1</sup>, J. Brett<sup>2</sup>, N. Khutoryansky<sup>2</sup>, V.R. Aroda<sup>1</sup>;

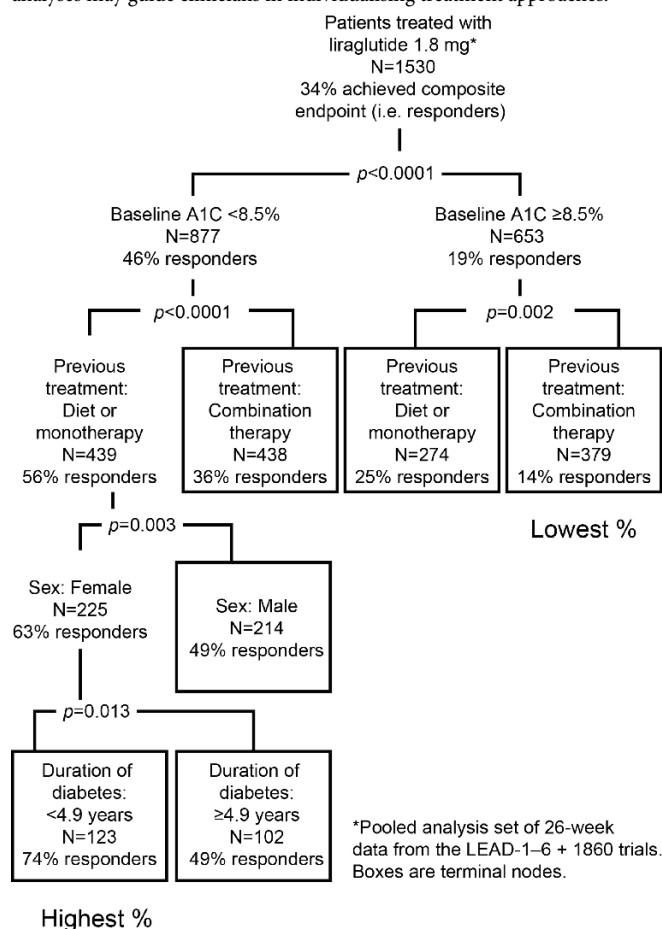

<sup>1</sup>MedStar Health Research Institute, Hyattsville, <sup>2</sup>Novo Nordisk Inc, Princeton, USA.

**Background and aims:** Randomised clinical trials provide unbiased databases for comparative effectiveness analyses to see which patients respond best to available interventions.

**Materials and methods:** We evaluated patient-level data pooled from seven Phase 3 clinical trials with liraglutide to examine responder subgroups, as defined by those achieving a composite endpoint of HbA<sub>1c</sub> <7%, no weight gain and no hypoglycaemia (episodes requiring assistance or self-treated with PG <56 mg/dL [3.1<mmol/L]) over 26 weeks.

**Results:** Overall 34% of individuals on liraglutide 1.8 mg achieved the pre-specified composite endpoint. Candidate predictor variables included baseline age, sex, ethnicity, BMI, HbA<sub>1c</sub>, beta-cell function, FPG, insulin resistance, previous treatments, and diabetes duration. Using recursive partitioning to create classification trees, baseline HbA<sub>1c</sub> was the most significant predictor, with a probability of achieving the composite outcome of 46% when baseline HbA<sub>1c</sub> <8.5%, as opposed to 19% if baseline HbA<sub>1c</sub> ≥8.5% ( $p<0.0001$ ). Subsequent splits (with  $p$ -values <0.05) produced a subgroup within patients with a baseline HbA<sub>1c</sub> <8.5% that was identified by previous treatment with diet or monotherapy, female sex, and diabetes duration <4.9 years increasing probability of success to 74%. Six homogeneous subgroups were identified with different probabilities of achieving the composite outcome (Fig).

**Conclusion:** In summary, recursive partitioning identified individual characteristics and subgroups of patients predicting the response to therapy. Such analyses may guide clinicians in individualising treatment approaches.

### Once-daily lixisenatide added on to consistently titrated insulin glargine plus oral agents in type 2 diabetes: the GetGoal-Duo 1 study

J. Rosenstock<sup>1</sup>, T. Forst<sup>2</sup>, R. Aronson<sup>3</sup>, L. Sauque Reyna<sup>4</sup>, E. Souhami<sup>5</sup>, S. Ping<sup>6</sup>, M. Riddle<sup>7</sup>;

<sup>1</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA,

<sup>2</sup>Institute for Clinical Research and Development, Mainz, Germany,

<sup>3</sup>LMC Endocrinology Centres, Toronto, Canada, <sup>4</sup>Unidad Metabólica y Cardiovascular SC de Cuernavaca, Mexico, <sup>5</sup>Sanofi, Paris, France, <sup>6</sup>Sanofi, Bridgewater, USA, <sup>7</sup>Oregon Health and Science University, Portland, USA.

**Background and aims:** Lixisenatide is a once-daily glucagon-like peptide 1 (GLP-1) receptor agonist with robust postprandial effects that could complement basal insulin therapy. This randomized, double-blind, multicentre trial in Type 2 diabetes mellitus (T2DM) inadequately controlled on metformin ± sulfonylureas ± thiazolidinediones (TZDs) assessed the efficacy and safety of lixisenatide added on to titrated insulin glargine + metformin ± TZDs.

**Materials and methods:** Glargine was initiated and titrated in a 12-week run-in phase to achieve fasting plasma glucose 4.4–5.6 mmol/L. People with HbA<sub>1c</sub> ≥7.0% and ≤9.0%, and whose mean fasting self-monitored plasma glucose was ≤7.8 mmol/L were then randomized to morning injections of once-daily lixisenatide 20 µg (n=223) or placebo (n=223) for 24 weeks while glargine titration continued. At randomization, sulfonylureas were stopped; all participants received metformin and 12% also received a TZD.

**Results:** Patient demographics were similar in both groups (mean age 56.2 years, T2DM duration 9.2 years, BMI 31.8 kg/m<sup>2</sup>). Primary endpoint was change in HbA<sub>1c</sub> from randomization. HbA<sub>1c</sub> initially decreased during run-in from 8.6 to 7.6%, and lixisenatide further reduced HbA<sub>1c</sub> by 0.71 versus 0.40% with placebo with consistent glargine titration at Week 24 (least squares [LS] mean difference: -0.32%; p<0.0001). Significantly more lixisenatide patients achieved HbA<sub>1c</sub> <7.0% (56 vs 39% with placebo; p=0.0001). Lixisenatide significantly improved 2-h postprandial glucose (PPG) after a standardized breakfast, and had a beneficial effect on body weight versus placebo despite titration of glargine doses (LS mean difference: -0.89 kg; p=0.0012). Adverse events (AEs) occurred in 80% of lixisenatide participants versus 68% on placebo; nausea/vomiting were more common with lixisenatide (27.4/9.4% vs 4.9/1.3%), as was discontinuation due to AEs (8.5 vs 3.6%). Nausea and vomiting were the most common AEs leading to discontinuation in the lixisenatide group (total of 4.0 vs 0.0% in the placebo group). Documented hypoglycaemia (blood glucose <3.3 mmol/L) was reported in 20.2% of the lixisenatide-treated patients versus 11.7% of those receiving placebo, with only 0.80 versus 0.44 events/patient/year, respectively. There was only one episode of severe hypoglycaemia in the lixisenatide group (0.4%) and none with placebo.

**Conclusion:** Lixisenatide added to consistently titrated insulin glargine plus oral agents significantly improved HbA<sub>1c</sub>, reduced PPG and had a beneficial effect on weight, with an expected GLP-1 AE profile that subsided over time.

Efficacy parameters in mITT population		Lixisenatide (n=223)	Placebo (n=223)

### Effects of lixisenatide once daily on gastric emptying and its relationship to postprandial glycaemia in type 2 diabetes mellitus

M. Lorenz, C. Pfeiffer, A. Steinsträßer, P. Ruus, R. Becker;

Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany.

**Background and aims:** Lixisenatide is a glucagon-like peptide-1 (GLP-1) receptor agonist intended for the treatment of patients with Type 2 diabetes mellitus (T2DM). Lixisenatide blunts postprandial blood glucose (PPBG) excursions by delaying gastric emptying in addition to stimulating glucose-dependent insulin release and suppressing glucagon secretion. This study evaluated the relationship between the gastric emptying rate and PPBG-area under the curve (AUC) values after intake of mixed meals in patients with T2DM receiving lixisenatide 20 µg once daily (QD) or placebo in the morning.

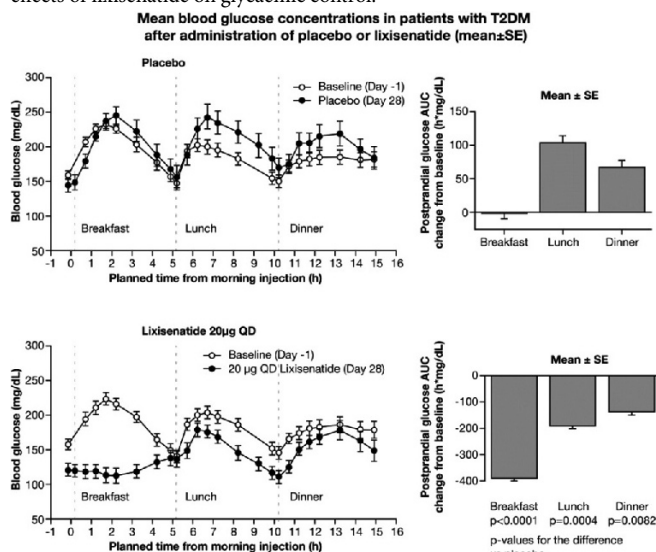

**Materials and methods:** Data were obtained from a 28-day, randomized, double-blind, placebo-controlled, parallel-group study (lixisenatide n=19; placebo n=22) in patients with T2DM on top of up to two oral antidiabetic agents. Lixisenatide was injected subcutaneously QD using an ascending dose range beginning at 5 µg and increasing in increments of 2.5 µg over 4-day intervals to a final dose of 20 µg QD from Day 25 to Day 28. In addition to 24-hour blood glucose monitoring, a <sup>13</sup>C-octanoic acid breath test was conducted to explore the gastric emptying rate during a standardized breakfast at Day 28.

**Results:** For lixisenatide 20 µg QD in the morning, the change in PPBG-AUC on Day 28 corrected for values at baseline (Day -1 prior to initiation of study treatment) was significantly reduced compared with placebo after a standardized breakfast (p<0.0001; Figure), after lunch (p=0.0004) and after dinner (p=0.0082). Thus, lixisenatide 20 µg QD administered in the morning demonstrated a pharmacodynamic effect on blood glucose levels after all meals throughout the day. The mean gastric emptying half-life (t<sub>1/2</sub>) was significantly longer for lixisenatide 20 µg compared with placebo (p=0.0031); mean (± standard deviation) changes from baseline for t<sub>1/2</sub> were -24 ± 133 minutes for placebo (n=17) and 212 ± 279 minutes for lixisenatide (n=17). There was an inverse relationship between PPBG and gastric emptying rate for lixisenatide after the standardized breakfast; linear regression of PPBG-AUC<sub>0.14–4.55h</sub> versus t<sub>1/2</sub> (n=17, r<sup>2</sup>=0.4889; p=0.0018).

**Conclusion:** Lixisenatide 20 µg QD injected subcutaneously in the morning significantly slows gastric emptying accompanied by a significant PPBG re-

duction, which is considered to be an important mechanism for the beneficial effects of lixisenatide on glycaemic control.

### Anti-atherosclerotic activity of lixisenatide in ApoE knockout mice

T. Hübschle, H.-L. Schäfer, H.-P. Juretschke, H. Rütten, U. Werner; Sanofi-Aventis Deutschland GmbH, Translational Medicine, Frankfurt am Main, Germany.

**Background and aims:** The ApoE knockout (KO) mouse develops atherosclerotic plaques with morphology resembling human atherosclerosis. This model was used to investigate the effects of chronic lixisenatide treatment on atherosclerotic plaque formation.

**Materials and methods:** Male ApoE KO mice (B.129P2-apoe<sup>tm1Unc/J</sup>) were treated for 16 weeks by continuous infusion via subcutaneous osmotic minipumps (ALZET™). Animals received 3.6 µg/day for the first 4 weeks and 5.04 µg/day for the subsequent 12 weeks. ApoE KO control mice received the same volume of placebo. Untreated mice from the background strain (C57BL/6J) were used as a second, healthy control.

**Results:** Total serum cholesterol and blood glucose were significantly reduced by lixisenatide both during (-41 and -10%, respectively, Day 35) and at the end of treatment (-42 and -13%, respectively, Day 112). The decrease in total serum cholesterol was related to a decrease in atherogenic lipoprotein fractions. Treatment with lixisenatide had no significant effect on relative liver weight, hepatic cholesterol, triglyceride or phospholipid concentrations at study end. After 16 weeks of lixisenatide treatment, three methodologically independent measures (invasive [macroscopic and histology] and non-invasive [ultra-small superparamagnetic iron oxide (USPIO)-based magnetic resonance imaging (MRI)]) were used to quantify atherosclerotic plaque formation. When compared with the wild-type background, ApoE KO mice receiving placebo developed atherosclerotic lesions at the total inner surface of the aorta and the aortic root semilunar valve region of the heart. In contrast, lixisenatide treatment in ApoE KO mice resulted in a significant reduction of atherosclerotic plaque formation of ~30% relative to placebo. In more detail, lixisenatide significantly reduced atherosclerotic lesions at the total inner surface of the aorta by 27% (oil red staining) and at the aortic root semilunar valve region by 29% (Movat-Pentachrome staining) or 30% (USPIO-based MRI).

**Conclusion:** Lixisenatide was associated with robust anti-atherosclerotic activity with a significant reduction of atherogenic lipoproteins in ApoE KO mice.

### Efficacy and safety of lixisenatide once daily versus placebo in patients with type 2 diabetes insufficiently controlled on pioglitazone (GetGoal-P)

M. Pinget<sup>1</sup>, R. Goldenberg<sup>2</sup>, E. Niemoeller<sup>3</sup>, I. Muehlenbartmer<sup>4</sup>, R. Aronson<sup>5</sup>;

<sup>1</sup>University Hospital Strasbourg, France, <sup>2</sup>LMC Diabetes and Endocrinology, Thornhill, Canada, <sup>3</sup>Sanofi-aventis Deutschland GmbH, Frankfurt am Main, Germany, <sup>4</sup>Sanofi, Paris, France, <sup>5</sup>LMC Endocrinology Centres, Toronto, Canada.

**Background and aims:** Lixisenatide is a once-daily glucagon-like peptide-1 (GLP-1) receptor agonist for the treatment of Type 2 diabetes mellitus (T2DM). The aim of the GetGoal-P study was to evaluate the efficacy and safety of lixisenatide (LIXI) as add-on therapy in patients with T2DM insufficiently controlled by ≥30 mg/day pioglitazone ± metformin.

**Materials and methods:** GetGoal-P was a randomized, double-blind, placebo-controlled, multicentre study comparing the efficacy and safety of lixisenatide 20 µg once daily versus placebo (PBO). The primary objective was the absolute HbA<sub>1c</sub> reduction with LIXI versus PBO at Week 24 (main treatment period).

**Results:** At baseline, mean age was 55.8 years old, mean diabetes duration 8.1 years, mean HbA<sub>1c</sub> 8.1% and mean BMI 33.9 kg/m<sup>2</sup>. LIXI once daily produced a significantly greater HbA<sub>1c</sub> reduction versus placebo (Table) and a greater proportion of patients achieved HbA<sub>1c</sub> <7.0% (52% LIXI vs 26% PBO; p<0.0001). Significantly fewer patients receiving LIXI required rescue therapy (3.8 vs 11.3% PBO). Overall, LIXI was well tolerated, with a similar proportion of adverse events and serious adverse events (72.4 and 2.5% in the LIXI group versus 72.7 and 1.9% in the placebo group). Only 6.5% of LIXI and 5.0% of PBO-treated patients discontinued due to adverse events at Week 24, mainly related to gastrointestinal events (Table). Symptomatic hypoglycaemia rates were low in both groups (Table). There were no cases of severe hypoglycaemia in either group.

**Conclusion:** In conclusion, in patients with T2DM insufficiently controlled on pioglitazone ± metformin, LIXI 20 µg once daily significantly improved glycaemic control with a low risk of hypoglycaemia and was well tolerated over 24 weeks.

**Cardioprotective effect of chronic treatment with lixisenatide in an *in vivo* rat model of myocardial ischaemia/reperfusion-induced injury**P. Wohlfart<sup>1</sup>, W. Linz<sup>1</sup>, D. Linz<sup>2</sup>, T. Hübschle<sup>1</sup>, U. Werner<sup>1</sup>, H. Ruetten<sup>1</sup>;<sup>1</sup>Sanofi-Aventis Deutschland GmbH, Translational Medicine, Frankfurt am Main, <sup>2</sup>Saarland University – Faculty of Medicine, Homburg/Saar, Germany.

**Background and aims:** Effects of glucagon-like peptide-1 receptor (GLP-1R) agonists on the cardiovascular system have been described recently. In isolated rat hearts, the GLP-1R agonist lixisenatide significantly reduced infarct size after ischaemia reperfusion (I/R) *ex vivo*. In this study, the effect of chronic lixisenatide treatment versus placebo on cardiovascular outcome after ischaemia (30 minutes) and long-term reperfusion of the left coronary artery was investigated *in vivo*.

**Materials and methods:** Male Wistar rats (250–300 g) were randomized into four groups: 1) sham-operated controls without I/R (Sham); 2) I/R placebo; 3) I/R ramipril (1 mg/kg/day in chow); 4) I/R lixisenatide (10 µg/kg/day subcutaneously via osmotic mini-pump). After 10 weeks of treatment, heart function was investigated via tip catheter, an autopsy performed and the lungs were weighed. Plasma brain natriuretic peptide (BNP) was determined as a marker of chronic heart failure.

**Results:** Lixisenatide significantly attenuated I/R-induced deterioration of diastolic function (left ventricular end-diastolic pressure) and Tau Weiss, a measure of myocardial relaxation (Figure). Lung weight was significantly increased with placebo (a measure of congestion), but was normalized by lixisenatide and ramipril (Figure). Moreover, BNP levels were significantly ( $p<0.05$ ) reduced by either agent. Thus, deterioration of left ventricular function following I/R was significantly prevented by chronic lixisenatide treatment.

**Conclusion:** In conclusion, lixisenatide has shown, in a rat model of myocardial I/R-induced injury, cardioprotective effects comparable with the angiotensin-converting enzyme inhibitor ramipril.

## 812

**Absence of calcitonin response in GLP-1R knock-out mice after treatment with lixisenatide**T. Kissner<sup>1</sup>, L. Essermeant<sup>2</sup>, J.-F. Gallas<sup>2</sup>, G. Hadour<sup>2</sup>;<sup>1</sup>Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany, <sup>2</sup>Sanofi, Montpellier, France.

**Background and aims:** Proliferative C-cell findings in rodent thyroid have been reported in long-term pre-clinical studies with glucagon-like peptide-1 receptor (GLP-1R) agonists. The association between calcitonin level and thyroid C-cell proliferation has been recently debated. Plasma calcitonin is increased in association with C-cell proliferation in rodents at very high doses and also in shorter-term studies without C-cell proliferation. Using GLP-1R knockout (KO) mice, we investigated the hypothesis that calcitonin release at high lixisenatide doses is mediated via GLP-1R activation.

**Materials and methods:** Male and female CD-1 (wild-type) mice and GLP-1R (-/-) KO mice based on CD-1 genetic background were given high subcutaneous (SC) doses of lixisenatide 1000 µg/kg twice daily or control vehicle for 14 days (n=8/group). Plasma calcitonin concentration was measured by immune-radiometric assay 2 hours after last administration on Day 14. As 50% of calcitonin values were under the lower limit of quantification (10 pg/mL), an exact pairwise Wilcoxon's test was used to analyse between-group differences.

**Results:** In CD-1 mice, lixisenatide treatment resulted in statistically significant higher mean plasma calcitonin concentrations versus control (Table;  $p<0.001$  for pooled male/female animals). No lixisenatide-induced calcitonin release was noted in GLP-1R (-/-) KO mice ( $p$ =non-significant). In this group, the plasma calcitonin concentration remained low and similar to values observed in CD-1 and control GLP-1R (-/-) KO mice. Moreover, at this dose level, no C-cell proliferation was seen in studies up to 3 months in CD-1 mice.

**Conclusion:** The absence of lixisenatide-induced calcitonin release in GLP-1R (-/-) KO mice, in contrast to wild-type mice, suggests that the GLP-1R is involved in the rodent thyroid pathway of C-cell activation and causes calcitonin release. In addition, in this study calcitonin increase was not associated with thyroid C-cell proliferation.

Mean calcitonin levels in CD-1 (wild-type) and GLP-1R (-/-) KO mouse plasma on Day 14

Animal strain and treatment	Gender	Calcitonin concentration (pg/mL) on Day 14 (Mean ± SD)
CD-1 (wild-type), Control vehicle	Female (n=6)	<16.6 ± NA
	Male (n=2)	<15 ± NA
CD-1 (wild-type), Lixisenatide 1000 µg/kg twice daily	Female (n=5)	99.8 ± 50.9
	Male (n=3)	86.6 ± 29.8
GLP-1R (-/-) KO, Control vehicle	Female (n=6)	10.7 ± NA
	Male (n=2)	<18.8 ± NA
GLP-1R (-/-) KO, Lixisenatide 1000 µg/kg twice daily	Female (n=5)	<10.1 ± NA
	Male (n=3)	<16.5 ± 8.7

For values below the lower limit of quantification (LLOQ), LLOQ was used to calculate the maximum bound for the mean; NA=not applicable, as either all values or more than 50% of values were below the LLOQ; GLP-1R=glucagon-like peptide-1 receptor; KO=knockout; SD=standard deviation

**Restitution of glucose disposition with lixisenatide in subjects with type 2 diabetes**R.H. Becker<sup>1</sup>, C. Kapitza<sup>2</sup>, J. Stechl<sup>1</sup>, P. Ruus<sup>1</sup>, J. Msihid<sup>3</sup>;<sup>1</sup>Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany, <sup>2</sup>Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany, <sup>3</sup>Sanofi, Paris, France.

**Background and aims:** Restitution of glucose disposition is a therapeutic goal in Type 2 diabetes mellitus (T2DM). We compared insulin secretion (IS) and glucose disposition with lixisenatide (LIXI) in early-stage T2DM and non-diabetic healthy subjects.

**Materials and methods:** In two single-centre, two-period, two-treatment, two-sequence, single-dose, crossover studies, healthy subjects (14 male/six female, mean age 36 years old, BMI 25 kg/m<sup>2</sup>) and patients with T2DM (13 male/nine female, mean age 55 years old, BMI 30 kg/m<sup>2</sup>) received LIXI 20 µg subcutaneously or placebo (PBO) 2 hours prior to an intravenous glucose challenge (IVG; 0.3 g/kg over 30 seconds). Integration of IS rate (ISR) by C-peptide deconvolution was used to determine first- (ISR-AUC<sub>0-10min</sub>) and second- (ISR-AUC<sub>10-120min</sub>) phase insulin secretion. Insulin, C-peptide and glucagon concentration-time curves and glucose disposition rate ( $K_{glu}$ ) were determined for 2 hours.

**Results:** LIXI enhanced first-phase insulin secretion in T2DM to PBO levels in healthy subjects, while second-phase insulin secretion was greater and elevated for >2 hours in subjects with T2DM, in both PBO and LIXI groups (Figure). Insulin and C-peptide were correspondingly greater.  $K_{glu}$  was accelerated twofold by LIXI, but did not fully recover to values in healthy subjects. When insulin levels changed, glucagon levels followed inversely and glucose was brought to normal levels.

**Conclusion:** A single dose of LIXI 20 µg quantitatively restored first-phase insulin release to IVG in subjects with T2DM, enlarged second-phase insulin secretion and enhanced glucose disposition towards normal values, without impairing counter-regulation by glucagon.

### Augmentation of first-phase insulin release with lixisenatide in non-diabetic subjects

J. Stechl<sup>1</sup>, R.H. Becker<sup>1</sup>, C. Kapitza<sup>2</sup>, J. Msihid<sup>3</sup>;

<sup>1</sup>Sanofi, Frankfurt am Main, Germany, <sup>2</sup>Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany, <sup>3</sup>Sanofi, Paris, France.

**Background and aims:** Lixisenatide restores insulin release and accelerates glucose disposition in Type 2 diabetes. We investigated the physiological response in non-diabetic subjects.

**Materials and methods:** In a two-period, two-treatment, two-sequence, single-centre, single-dose, crossover study, subjects (14 male, six female, mean age 36 years old, BMI 24 kg/m<sup>2</sup>) received single doses of lixisenatide 20 µg subcutaneously (SC) or matching placebo 2 hours prior to an intravenous glucose challenge (IVG; 0.3 g/kg over 30 seconds). First- (AUC<sub>0-10min</sub>) and second- (AUC<sub>10-120min</sub>) phase insulin secretion was integrated from the insulin secretion rate (based on C-peptide measurement).

**Results:** Maximum plasma lixisenatide concentration ( $C_{max}$  145 pg/mL; coefficient of variance [CV%] 44) occurred 2 hours (range 1–3 hours) after injection, with weak transient effects on fasting blood glucose and pre-IVG insulin levels. Lixisenatide enhanced first-phase insulin secretion 2.4-fold (90% confidence interval [CI]: 2.1–2.6), while second-phase release was unchanged overall, 0.9-fold (90% CI: 0.8–1.0), but was elevated up to 30 minutes and subsequently dropped sharply to baseline, differing significantly from placebo, which remained elevated. First- and second-phase insulin concentration increased 3.2-fold (90% CI: 2.7–3.8) and 3.4-fold (90% CI: 2.7–4.2), followed by 2.3-fold (90% CI: 1.9–3.0) accelerated glucose disposition, reducing blood glucose below counter-regulatory thresholds (<3.9 mmol/L) in some subjects.

Glucagon suppression was initially augmented and recovered faster in those with blood glucose <3.9 mmol/L.

**Conclusion:** A single dose of lixisenatide 20 µg SC boosts insulin release to IVG and accelerates glucose disposition in non-diabetic subjects without affecting the counter-regulatory interplay of insulin and glucagon release, thus maintaining euglycaemia.

### Efficacy and safety of lixisenatide in elderly (≥65 years) and very elderly (≥75 years) patients with type 2 diabetes: an analysis from the GetGoal Phase 3 programme

D. Raccach<sup>1</sup>, P. Miossec<sup>2</sup>, V. Esposito<sup>2</sup>, E. Niemoeller<sup>3</sup>, M. Cho<sup>4</sup>, J. Gerich<sup>5</sup>;

<sup>1</sup>Hôpital Sainte Marguerite, Marseille, France, <sup>2</sup>Sanofi R&D, Paris, France, <sup>3</sup>Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany, <sup>4</sup>Sanofi, Bridgewater, USA, <sup>5</sup>Department of Medicine, University of Rochester School of Medicine, Rochester, USA.

**Background and aims:** The number of elderly people with Type 2 diabetes mellitus (T2DM) is increasing due to improved life expectancy, and managing elderly patients with T2DM can be challenging. The effect of age on the pharmacokinetics of lixisenatide was assessed in a study that included 18 elderly healthy subjects (age range 65–79 years) and 18 young healthy subjects (age range 24–44 years). The mean exposure after a 20 µg single dose was ~30% higher in elderly than in young subjects and the terminal half-life was prolonged ~1.6 times.  $C_{max}$  and  $t_{max}$  were comparable in both groups. The aim of this analysis was to compare clinical outcomes for lixisenatide across age groups in the Phase III clinical trial programme.

**Materials and methods:** To date, 612 elderly patients (aged ≥65 years) overall have been exposed to lixisenatide in Phase II/III clinical trials (567.9 patient-years), including 59 very elderly (aged ≥75 years) patients (58.3 patient-years). This analysis of six randomized, placebo-controlled Phase III trials assessed the efficacy (HbA<sub>1c</sub>) and safety (overall adverse events, gastrointestinal events, hypoglycaemia) of 20 µg once-daily lixisenatide in 379 patients aged ≥65 years, including 48 patients aged ≥75 years (436.5 and 49.1 patient-years' exposure, respectively) during the main 12-week (GetGoal-Mono) or 24-week (GetGoal-M, -F1, -S, L, -L-Asia) treatment periods.

**Results:** The efficacy profiles were similar regardless of age, with comparable HbA<sub>1c</sub> decreases in patients aged ≥65 years versus patients aged <65 years for lixisenatide in all six studies, and significantly greater decreases versus placebo in both age categories. In a pooled analysis of the six studies, the lixisenatide safety profile was also comparable regardless of age, with overall adverse events and gastrointestinal event incidences in lixisenatide-treated patients of 72 and 43% in patients aged ≥65 years versus 69 and 41% in patients aged <65 years, and 73 and 46% in patients aged ≥75 years versus 69 and 41% in patients aged <75 years. The incidence of symptomatic hypoglycaemic events varied depending on the background treatment and was usually comparable between lixisenatide and placebo and no relevant difference between age categories was observed.

**Conclusion:** In conclusion, in this analysis, lixisenatide was shown to be effective and well tolerated in elderly and very elderly patients.

**C-peptide response to glucagon challenge predicts improvement by liraglutide of both early insulin secretion and glucose tolerance**T. Matsuda<sup>1</sup>, M. Takabe<sup>1</sup>, Y. Hirota<sup>1</sup>, N. Hashimoto<sup>1</sup>, T. Nakamura<sup>1</sup>, K. Sakaguchi<sup>1</sup>, W. Ogawa<sup>1</sup>, S. Seino<sup>1,2</sup>;<sup>1</sup>Division of Diabetes and Endocrinology, <sup>2</sup>Division of Cellular and Molecular Medicine, Kobe University Graduate School of Medicine, Kobe, Japan.

**Background and aims:** Liraglutide, a glucagon-like peptide-1 (GLP-1) receptor agonist, provides effective treatment for glycaemic control in type 2 diabetes mellitus (T2DM). The beneficial effects of liraglutide vary by individual, but little knowledge of clinical parameters to predict its effect is available. In this study, we investigated predictive factors for the effects of liraglutide on insulin secretion and glucose excursion in patients with T2DM.

**Materials and methods:** Patients with T2DM (N=24) were hospitalised and treated for glucose toxicity with oral hypoglycaemic agents and/or insulin. After achieving the target level of glycaemic control (fasting plasma glucose <130 mg/ dL, postprandial plasma glucose <180 mg/ dL), liraglutide treatment was started at a dose of 0.3 mg/day, and was gradually increased to 0.9 mg/day (the maximum dose approved in Japan) if tolerated. The final dose and treatment duration of liraglutide was  $0.79 \pm 0.19$  mg/day and  $17.5 \pm 1.7$  days (mean  $\pm$  SD), respectively. A 75g-oral glucose tolerance test (OGTT) and a glucagon challenge test (in which 1mg of glucagon was administered intravenously and the serum levels of CPR before and 6 min after the challenge were measured) were performed before treatment; a second OGTT was performed after treatment to assess the effects of liraglutide. The long-term effect of the drug also was assessed by the change in HbA1c level.

**Results:** Liraglutide improved glucose excursion without significant increase in total insulin secretion [area-under-the curve of plasma insulin (AUC insulin)] during OGTT [before treatment (before),  $4920 \pm 4735$   $\mu$ U/ml; after treatment (after),  $5958 \pm 3866$   $\mu$ U/ml,  $P=0.16$ ]. On the other hand, Insulinogenic Index (I.I.) (before,  $0.16 \pm 0.36$ ; after,  $0.57 \pm 0.55$ ,  $P=0.001$ ) and serum insulin level at 30 min (before,  $27.9 \pm 27.9$   $\mu$ U/ml; after,  $37.6 \pm 35.3$   $\mu$ U/ml,  $P=0.01$ ) and 60 min (before,  $40.5 \pm 38.6$   $\mu$ U/ml; after,  $63.9 \pm 65.1$   $\mu$ U/ml,  $P=0.02$ ) during OGTT were significantly increased by liraglutide. Serum CPR levels 6 min after glucagon administration (CPR 6min) showed the greatest correlation coefficient ( $r=0.92$ ) among the various parameters of insulin secretion obtained before treatment, including HOMA-beta index, fasting serum CPR level, ratio of fasting serum CPR to plasma glucose level, insulinogenic index, AUC insulin during OGTT, difference of serum CPR level before and after glucagon challenge test, and serum CPR after 6 min after glucagon challenge test (CPR 6min). When the effect of liraglutide in patients was categorised into tertiles by CPR 6min, the highest responders to the glucagon challenge test showed the greatest improvement in terms of early insulin response and glucose excursion during OGTT, and also in reduction of HbA1c level.

**Conclusion:** Improvement of glucose tolerance by liraglutide in T2DM patients is associated with increased early insulin secretion but not total insulin secretion (AUC insulin). Glucagon-stimulated CPR secretion may be a useful predictor for the effects of liraglutide in T2DM.

## 817

**Discovery of a novel potent and selective TGR5 agonists with anti-diabetic effect**

M. Ning, H. Duan, S. Huang, J. Shen, Y. Leng;

Shanghai Institute of Material Medica, Chinese Academy of Sciences, Shanghai, China.

**Background and aims:** TGR5 is a member of G-protein coupled receptor which coupled to the formation of cAMP that mediates various cellular and physiological effects. Activation of this receptor will promote the production of glucagons-like peptide (GLP-1) and upregulate genes which involved in the control of energy expenditure. Those advantages made TGR5 as an attractive target for the treatment of diabetes, obesity, and metabolic syndrome. In the present study, a novel potent and selective TGR5 agonist was discovered and its *in vivo* anti-diabetic effect was evaluated.

**Materials and methods:** The *in vitro* activation of human and mouse TGR5 was determined by cell based reporter gene assay in hTGR5/CRE/HEK293 and mTGR5/CRE/HEK293 cell lines. Glucose tolerance test and GLP-1 secretion was performed on ICR mice. The acute and chronic anti-diabetic effect was investigated in db/db and ob/ob mice.

**Results:** MN6 was discovered as a potent and selective TGR5 agonist with  $EC_{50}$  of 1.55 nM on human TGR5 and 17.8 nM on mouse TGR5, but no activation of FXR. Single oral dose of 50 mg/kg MN6 significantly decreased blood glucose levels following an OGTT in ICR mice, and caused 44.8% reduction of the area under the curve ( $AUC_{0-120min}$  Glu). Moreover, an acute administration of MN6 also enhanced both basal or glucose induced GLP-1 release in ICR mice. Single oral dose of 25 or 50 mg/kg MN6 decreased blood glucose levels in db/db mice, and the chronic administration of MN6 could significantly decrease the HbA1c levels in ob/ob mice.

**Conclusion:** MN6 is a novel and selective TGR5 receptor agonist, which showed good potency in both *in vitro* and *in vivo* assays. It might be a therapeutic candidate for the treatment of T2DM and metabolic syndrome.

## 818

**Glucagon receptor antagonist LY2409021 does not delay recovery from insulin induced hypoglycaemia in patients with type 2 diabetes mellitus**R. Kelly<sup>1</sup>, C.N. Lim<sup>1</sup>, E. Pratt<sup>1</sup>, M.T. Loh<sup>1</sup>, M. Deeg<sup>2</sup>, H. Fu<sup>2</sup>, S. Cui<sup>3</sup>, P. Garhyan<sup>2</sup>;<sup>1</sup>Eli Lilly, Singapore, <sup>2</sup>Eli Lilly, Indianapolis, USA, <sup>3</sup>Pharmanet/i3, Ann Arbor, USA.

**Background and aims:** In patients (pts) with type 2 diabetes mellitus (T2DM), glucagon receptor antagonism improves hyperglycaemia by inhibiting hepatic glucose output. It has not been studied whether an appropriate physiologic response to hypoglycaemia is preserved in the presence of a glucagon receptor blockade. LY2409021 (LY) is a selective and potent glucagon receptor antagonist. Our primary aim was to determine if recovery from hypoglycaemia in pts with T2DM is impeded by administration of LY vs. placebo (PB). Our secondary aim was to examine responses of counter-regulatory hormones under these conditions.

**Materials and methods:** Thirteen Asian pts (21 to 65 years) with T2DM ( $HbA_{1c} \leq 11.0\%$ ), half of whom were taking metformin (Met) (n=7), were enrolled in this single-site, single-dose, subject-blind study. Pts were randomised to 1 of 2 treatment sequences and received PB or 1 dose of 90 mg LY (a dose expected to achieve near maximal glucagon receptor antagonism) 12 hours before insulin infusion to achieve hypoglycaemia (blood glucose  $\approx 40$  mg/dL).

**Results:** With LY vs. PB, the LS mean insulin load required to achieve hypoglycemia was 1920 pmol/kg vs. 2170 pmol/kg. Mean time to recovery from hypoglycaemia to a blood glucose  $\geq 63$  mg/dL was similar between LY and PB, and among pts taking Met and not taking Met (Table). During hypoglycaemia, mean glucagon levels were 2- to 3-fold higher after LY than after PB. The AUC and  $C_{max}$  of epinephrine, norepinephrine, cortisol, and growth hormone responses to hypoglycaemia were comparable between groups. No deaths or serious adverse events occurred during the study.

**Conclusion:** LY does not hamper recovery from insulin-induced hypoglycaemia in pts with T2DM.

## Mean time to recovery from hypoglycaemia

	Overall		Met*		No Met	
	LY N=12	PB N=12	LY N=6	PB N=6	LY N=6	PB N=6
<b>LS mean time to recovery</b>	58.19	53.45	51.40	52.65	65.87	54.26
<b>Mean Ratio</b>	1.09		0.98		1.21	
<b>90% CI</b>	0.88, 1.35		0.71, 1.33		0.90, 1.64	
<b>P-value</b>	0.4928		0.8916		0.2720	

**Abbreviations:** LS=least squares, LY=LY2409021, Met=metformin, PB=placebo.

\*One patient taking Met was not included in the analysis due to lack of post-baseline data.

## Functional characterisation of a mouse-selective small molecule agonist of TGR5

M.D. Michael<sup>1</sup>, X. Ruan<sup>1</sup>, C.C. Cheng<sup>1</sup>, A.M. Siesky<sup>1</sup>, C. Dominguez<sup>2</sup>, S.G. Sanfeliciano<sup>2</sup>, C. Montero<sup>2</sup>, C.S. Suen<sup>1</sup>, Y. Xu<sup>1</sup>, D.A. Briere<sup>2</sup>;

<sup>1</sup>Lilly Research Laboratories, Indianapolis, <sup>2</sup>Lilly Research Laboratories, Alcobendas, Spain.

**Background and aims:** TGR5 (also called GPR109A and GPR131) is a G-protein coupled receptor that is expressed in intestine, brown adipose tissue (BAT), and gallbladder and is activated by bile acids. Activation of TGR5 in intestine stimulates cyclic AMP (cAMP) resulting in release of glucagon-like peptide-1 (GLP-1) from enteroendocrine cells, whereas activation of TGR5 in BAT has been reported to increase energy expenditure. In addition, activation of TGR5 has been recently shown to increase gallbladder filling with bile. Currently, the only published agonists of TGR5 are bile acids or bile acid analogs, which have demonstrated small increases on acute GLP-1 secretion, little to no effects on acute glucose tolerance, and small increases in gallbladder volume *in vivo*. Here we present the effects of a novel, non-steroidal small molecule agonist of TGR5 on GLP-1 and peptide YY (PYY) secretion, glucose tolerance, and gallbladder filling.

**Materials and methods:** cAMP and GLP-1 production were measured in compound 8440 stimulated STC-1 and NCI-H716 cells using Cisbio HTRF cAMP and Mesoscale GLP-1 kits. Wild-type C57BL/6 mice or TGR5 knock-out mice were orally dosed for 1–3 days with compounds with and without glucose, followed by timed measurements of glucose, insulin, and/or GLP-1. Gallbladder filling was measured by weighing bile from the gallbladder.

**Results:** In mouse enteroendocrine STC-1 cells, compound 8440 demonstrated potent cAMP production (580 nM EC<sub>50</sub>, 25-fold stimulation) and GLP-1 secretion (307 nM EC<sub>50</sub>, 5.7-fold stimulation). In human enteroendocrine NCI-H716 cells, compound 8440 demonstrated weak cAMP production (3095 nM EC<sub>50</sub>, 3.2-fold stimulation) and GLP-1 secretion (2656 nM EC<sub>50</sub>, 1.5-fold stimulation). Together, these data demonstrate that compound 8440 is a mouse-selective TGR5 agonist. In C57BL/6 mice, compound 8440 dose-dependently and time-dependently increased GLP-1 and PYY secretion. When dosed to C57BL/6 mice 15 min prior to an oral glucose tolerance test, compound 8440 caused a lowering of the glucose excursion, as well as superior and prolonged increases in GLP-1 and PYY, as compared to the dipeptidyl peptidase-4 inhibitor, sitagliptin. In addition, compound 8440 showed a dose-dependent increase in bile weight that could not be separated from doses that induced significant effects on GLP-1 secretion, PYY secretion, or lowering of glucose excursions in an oral glucose tolerance test. Lastly, compound 8440 failed to show any effects on GLP-1, PYY, and bile weight in TGR5 knockout mice.

**Conclusion:** These results demonstrate that compound 8440, a mouse-selective, non-steroidal TGR5 agonist, acutely induces significant GLP-1 and PYY secretion which leads to a lower glucose excursion in an oral glucose tolerance test. Importantly, the doses that reduce glucose excursion cannot be separated from doses that induce gallbladder filling. Overall, these data highlight the benefits and risks of using TGR5 agonists to treat diabetes and metabolic diseases.

## 820

## Effects of bile acid enemas on GLP-1 and PYY secretion in healthy humans

M.J. Bound<sup>1</sup>, T. Wu<sup>1</sup>, B. Gedulin<sup>2</sup>, M. Horowitz<sup>1</sup>, C.K. Rayner<sup>1</sup>;

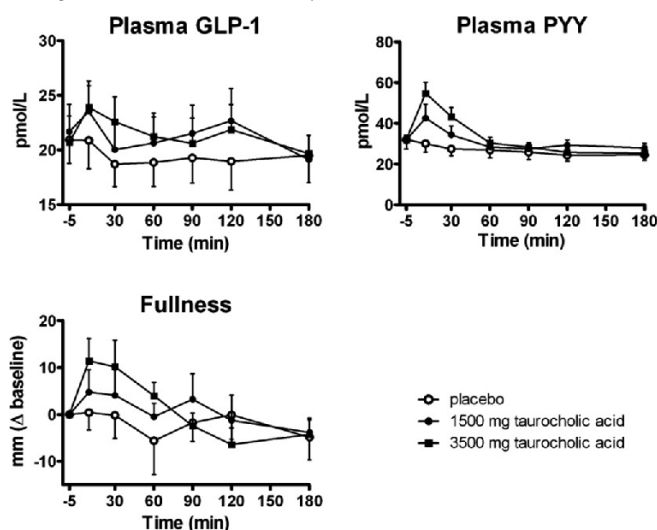

<sup>1</sup>Discipline of Medicine, University of Adelaide, Australia, <sup>2</sup>Satiogen Pharmaceuticals, San Diego, USA.

**Background and aims:** Glucagon like peptide-1 (GLP-1) and peptide YY (PYY) are secreted by enteroendocrine L-cells found most densely in the colon and rectum, and are of fundamental importance in blood glucose and appetite regulation. In vitro and animal studies suggest that bile salts can stimulate GLP-1 and PYY secretion by TGR5 receptor activation. We sought to evaluate the effects of rectal infusion of taurocholic acid (TCA) on the release of GLP-1 and PYY in healthy humans.

**Materials and methods:** 10 healthy males were studied after an overnight fast on 3 occasions each, in double-blind, randomised fashion. On each day, 20 mL of 1% carboxymethyl cellulose gel containing 1500 mg or 3500 mg of TCA, or vehicle only (placebo), was infused into the rectum (T = 0 min). Blood was sampled at intervals for 180 min for total GLP-1 and PYY, and gastrointestinal sensations were evaluated by 100 mm visual analogue scales. Data are mean  $\pm$  SEM. Hormone secretion was analysed as incremental area under the curve (iAUC).

**Results:** TCA enemas stimulated secretion of both GLP-1 (1500 mg TCA: 233.4  $\pm$  116.3 pmol/L  $\times$  min, 3500 mg TCA: 390.2  $\pm$  84.7 pmol/L  $\times$  min vs placebo: 61.4  $\pm$  23.4 pmol/L  $\times$  min, P = 0.019) and PYY (1500 mg TCA: 452.8  $\pm$  192.2 pmol/L  $\times$  min, 3500 mg TCA: 827.2  $\pm$  199.2 pmol/L  $\times$  min vs placebo: 4.8  $\pm$  3.2 pmol/L  $\times$  min, P = 0.0005), and the iAUC for each demonstrated a dose-dependent relationship (r = 0.48, P = 0.004 for GLP-1, and r = 0.56, P = 0.001 for PYY). Fullness was greater after 3500mg TCA than placebo (P < 0.05), without a significant difference between 1500mg TCA and placebo.

**Conclusion:** Rectal infusion of TCA stimulates GLP-1 and PYY, and increases fullness, in a dose-dependent manner in healthy humans, establishing the concept that topical application of bile acids has therapeutic potential for the management of diabetes and obesity.

## Safety, pharmacokinetics, and pharmacodynamics of a single subcutaneous dose of VRS-859 in patients with type 2 diabetes

J. Cleland<sup>1</sup>, R. Aronson<sup>2</sup>, E. Humphris<sup>1</sup>, C.R. Shore<sup>1</sup>, G. Bright<sup>1</sup>, R. Zhou<sup>3</sup>, M.S. Kipnes<sup>4</sup>;

<sup>1</sup>Diartis Pharmaceuticals, Redwood City, <sup>2</sup>LMC Endocrinology Center, Toronto, Canada, <sup>3</sup>Medpace, Cincinnati, <sup>4</sup>DGD Clinic, San Antonio, USA.

**Background and aims:** VRS-859, a GLP-1 analog XTEN fusion protein, was compared to placebo in a single ascending dose (SAD) study in patients with type 2 diabetes mellitus (T2DM) using concurrent metformin monotherapy.

**Materials and methods:** The study used a randomized, multi-centre, placebo-controlled, double blind, SAD design to evaluate the safety/tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of subcutaneous (SC) VRS-859. The study group included patients with T2DM currently treated with metformin. After screening, subjects received placebo (PBO) or VRS-859 (12.5, 25, 50, 100, 150 or 200 mg) as a single SC dose. In each dosing group, 8 patients received VRS-859 and 3 patients received PBO. PK and PD measurements (fasting glucose (FG), insulin, and oral glucose tolerance test (oGTT)) were performed on Days -1, 4, 8, 11, 15, 18, 22, 25, and 30. Safety assessments including calcitonin, lipase, and amylase levels as well as QTc analyses were performed through Day 30. Anti-VRS-859 antibody analyses are performed at Day -1, Day 30 and on follow-up at Day 60. HbA<sub>1c</sub> and body weight were measured at Day -1 and Day 30.

**Results:** 70 patients (56% M) were randomized in the study (mean values: 52 y, 93 kg, 8.2% HbA<sub>1c</sub>, 171 mg/dL FG). 52 T2DM patients were treated with VRS-859 and 18 T2DM patients were treated with PBO. No serious adverse events were reported and no patients dropped out of the study. No changes in QTc interval were observed. 8 of 52 patients had a low titer (<25) anti-VRS-859 antibody response at Day 60 that was specific to exenatide. No systematic or significant individual changes in lipase, amylase, and calcitonin levels were observed through Day 30. VRS-859 was well tolerated at all dose levels including the maximum dose, 200 mg. GI adverse events were generally mild, transient, occurred prior to C<sub>max</sub> and resolved in <24 hrs. VRS-859 PK was dose linear with an average T<sub>max</sub> of 90 hr, and an average t<sub>1/2</sub> of 128 hr. VRS-859 normalized fasting glucose (<7.2 mM) in 7 of 8 patients after a single dose of 200 mg without hypoglycemia. There was a strong correlation between VRS-859 plasma concentrations and FG ( $r = -0.63$ ,  $P < 0.0001$ ). Reductions in glucose excursions post-OGTT also correlated with VRS-859 plasma concentrations. A single dose of 200 mg VRS-859 resulted in mean reductions in HbA<sub>1c</sub> and body weight of 0.61% and 0.89 kg, respectively, at Day 30. Patients with an HbA<sub>1c</sub> above 7% (n=5) in the 200 mg VRS-859 dose group had a mean HbA<sub>1c</sub> reduction of 1.06% at Day 30 after a single dose.

**Conclusion:** VRS-859 was well tolerated and provided glycemic control in T2DM patients, and monthly doses may provide sustained reductions in HbA<sub>1c</sub> and body weight.

Clinical Trial Registration Number: Eudract number: 2010-019182-29

## 822

### KRP-104, a uniquely prandial-targeted DPP4 inhibitor

D.J. Plotkin<sup>1</sup>, A. Lewin<sup>2</sup>, D. Logan<sup>3</sup>, T. Kato<sup>4</sup>, J. Kozarich<sup>1</sup>, X. Wei<sup>3</sup>, J. Vest<sup>3</sup>, D. Orloff<sup>3</sup>

<sup>1</sup>ActivX Biosciences, Inc, La Jolla, USA, <sup>2</sup>National Research Institute, Los Angeles, USA, <sup>3</sup>Medpace, Cincinnati, USA, <sup>4</sup>Kyorin Pharmaceutical Co, Ltd, Tokyo, Japan.

**Background and aims:** Dipeptidyl peptidase4 inhibitors (DPP4i) used to treat hyperglycemia exhibit differential potency depending on incretin release stimulated by glucose intake. Unlike currently available DPP4i that are continuous inhibitors of DPP4 due to their PK/PD profiles, in Phase (P)1, KRP-104 (KRP) had a PK/PD profile with a unique dose by duration response enabling either continuous or daytime, i.e. prandial-specific, DPP4 inhibition depending on dose. The aim of the KRP P1-P2 clinical develop-

ment program was to test and compare the glycemic effects of these contrasting inh profiles.

**Materials and methods:** Glycemic efficacy of continuous (Con) vs prandial (prand) only DPP4 inh was assessed in 3 studies in type 2 diabetics. P1b: 2-period open-label, balanced cross-over, 7days/period, KRP vs 100mg daily sitagliptin (sita), 14 pts/group. Group 1, KRP 80mg twice daily; Group 2, KRP 70mg daily (60mg in AM, 10mg with dinner). P2a: 12 week (wk) randomized (R), double-blind (DB), KRP 120mg once daily, 60mg twice daily, or placebo (PBO)(1:1:1) on stable metformin, n=213. P2b: 24 wk R, DB, KRP 20/120mg (dose up titrated at wk 12), 40mg, 80mg, 100mg or PBO once daily (1:1:1:1:1) on stable metformin, n=403.

**Results:** P1b KRP vs Sita. Group1: KRP at 80mg twice daily produced Con-inh of ~90-95% and glycemic efficacy similar to sita at =>80% Con-inh assessed by fasting plasma glucose (FPG), 7 point glucose (G), or Con G monitoring. No increase in glycemic effect was seen with higher inh (Table). Group2: Prand-only inhibition by KRP (70mg) achieved comparable glycemic efficacy to sita (Table). P2a Diurnal Profile Assessment: KRP 120mg once daily (prand-inh); 60mg twice daily (=>80% Con-inh). After 12 wks, there was a statistically significant change from baseline compared to PBO for both KRP groups for HbA<sub>1c</sub> and FPG, but no significant difference between KRP groups (Table). Safety parameters were comparable among all 3 groups. P2b Dose Finding. As predicted by PK/PD modeling, after 12 and 24 wks treatment, 80mg was the lowest dose that achieved the maximum HbA<sub>1c</sub> reduction (LS mean, LOCF, -0.7% 24 wk) (Table).

**Conclusion:** In all 3 studies, KRP was well tolerated with a safety profile similar to controls. KRP demonstrated similar glycemic efficacy when dosed to inhibit DPP4 continuously or only during prandial hrs, and had comparable efficacy to sita even when dosed for only prand-inh or at higher levels of Con-inh. Thus, clinical studies with KRP demonstrated that the clinically meaningful glycemic benefit of DPP4i is mediated primarily during the prandial hours and inh =>80% is sufficient for maximal effect. Thus the KRP development dose of 80 mg once daily provides a diurnal on/off inh cycle; inh DPP4 during daytime for maximal glycemic control but releases DPP4 for other functions at night (when the impact on glycemic efficacy was negligible) to potentially boost chronic safety.

### KRP-104 diurnal effects on glycemic response

#### P1b: KRP-104 vs Sitagliptin

	KRP-104 n=14	Sitagliptin n=14

## 823

**The novel GLP-1-gastrin dual agonist ZP3022 improves glycaemic control in ZDF rats**

J. Skarbaliene, J.L. Tolborg, T.S.R. Neerup, K. Fosgerau;  
Zealand Pharma A/S, Glostrup, Denmark.

**Background and aims:** Combination treatment with exendin-4 and gastrin has been shown to improve diabetes and preserve  $\beta$ -cell mass by stimulating  $\beta$ -cell growth and differentiation in diabetic mice. Here we investigated the anti-diabetic effects of a novel GLP-1-gastrin dual agonist ZP3022 in Zucker Diabetic Fatty (ZDF) rats.

**Materials and methods:** ZDF rats aged 11 weeks were dosed s.c., bid for 8 weeks with either vehicle, ZP3022 (10, 40 nmol/kg), liraglutide (40 nmol/kg), exendin-4 (30 nmol/kg), gastrin17 (80 nmol/kg), or exendin-4 + gastrin17 (30 + 80 nmol/kg). HbA1c was measured at treatment start and at termination, an oral glucose tolerance test (OGTT) was performed after 5 weeks of treatment, and non-fasting blood glucose (BG) was measured every other week.

**Results:** The changes in HbA1c levels, BG AUCs during the OGTT, and non-fasting BG at the end of the study can be seen in Table 1. ZP3022 clearly improved glycaemic control as did all treatments, except gastrin17. Notably, ZP3022 caused a significantly greater reduction in HbA1c levels than liraglutide at equimolar dose. Only ZP3022 high dose, exendin-4 and exendin-4 + gastrin17 significantly improved glucose tolerance after an OGTT. Moreover, ZP3022 BG lowering effect was already present after 2-weeks of treatment and persistent throughout the study ( $P < 0.001$  vs. vehicle). Other treatments, except gastrin17, also had a significant BG lowering effect. However, the effect of liraglutide was transient.

**Conclusion:** In conclusion, treatment with ZP3022 markedly improved glycaemic control in diabetic ZDF rats, which indicate GLP-1-gastrin dual agonism as a possible target for the treatment of diabetes.

Table 1

Treatments	$\Delta$ HbA1c (%) termination- baseline	OGTT (mM) AUC <sub>0-240 min</sub> <sup>a</sup> Y=0	Non-fasting BG(mM) termination

## 824

**Incretin hormones in patients with type 2 diabetes are increased by diet-oil, a pro-drug for the GPR 119 receptor agonist, 2-oleoyl-glycerol**

M.J. Mandoe<sup>1</sup>, K.B. Hansen<sup>2</sup>, F.K. Knop<sup>3</sup>, J.J. Holst<sup>1</sup>, H.S. Hansen<sup>4</sup>;

<sup>1</sup>Department of Biomedical Sciences, NNF Center for Basic Metabolic Research, Copenhagen, <sup>2</sup>Department of Internal Medicine, Amager Hospital, Copenhagen, <sup>3</sup>Department of Internal Medicine, Gentofte Hospital,, <sup>4</sup>Department of Drug Design and Pharmacology, University of Copenhagen, Denmark.

**Background and aims:** Diet-oil (1,3-di-butyl-2-oleoyl-glycerol) is a precursor for the naturally occurring 2-oleoyl-glycerol (2-OG), which is a li-

gand for the G protein-coupled receptor GPR119, and causes release of the insulinotropic and glucagonostatic hormone, glucagon-like peptide-1 (GLP-1) from L cells in healthy subjects. The liberation of 2-OG from diet-oil is thought to occur more distally in the gut than 2-OG from olive oil (trioleoylglycerol). Because the density of L cells increases in the distal gut, diet-oil might generate a greater GLP-1 response than olive oil. 2-OG also stimulates release of glucose-dependent insulinotropic polypeptide (GIP).

**Materials and methods:** Diet-oil (and olive oil) were administered orally to 13 Caucasian patients with type 2 diabetes (8 males, age: 62±3 years (mean±SEM), body mass index: 30.4±2.5 kg/m<sup>2</sup>, fasting plasma glucose: 8.9±1 mmol/l, HbA<sub>1c</sub>: 6.9±0.4%) in a randomised, single-blinded cross-over study. The subjects were given the following meals on 3 different days: 200 g grated carrot, 200 g grated carrot + 20 g olive oil, or 200 g grated carrot +10.7 g diet-oil. Theoretically, the two oil regimes both result in formation of 7.7 g 2-OG during digestion. Primary outcomes were total GLP-1 and GIP measured in plasma.

**Results:** Olive oil and diet-oil resulted in significantly ( $p \leq 0.01$ ) greater post-prandial GLP-1 and GIP responses [GLP-1: incremental area under curve 845 and 710 pmol/l×180 min,  $p=0.41$ ; GIP: 4337 and 2926 pmol/l×180 min,  $p=0.08$ ] compared to the carrot meal (386 pmol/l×180 min and 874 pmol/l×180 min).

**Conclusion:** Diet-oil enhanced secretion of GLP-1 and GIP (compared to carbohydrate alone) to almost the same extent as olive oil, although olive oil liberates not only 2-OG, but in addition two oleic acid molecules, which may also stimulate incretin secretion. Thus, diet oil is more effective as incretin releaser than olive oil per unit of energy content and could be useful for dietary intervention.

**Pharmacokinetics and pharmacodynamics of a new exenatide formulation, exenatide suspension**

L. Porter, S. Flore, B. Cirincione, M. Zierhut, C. Biwald, W. Huang, T. Booker Porter, L. MacConell;

Amylin Pharmaceuticals, Inc., San Diego, USA.

**Background and aims:** Exenatide, a GLP-1 receptor agonist, has been shown to improve glycaemic control and body weight with twice-daily or once-weekly subcutaneous injections in patients with T2DM. Exenatide suspension uses the exact same drug substance and drug load (5% by mass) in extended-release microspheres as exenatide once weekly (EQW) but is reformulated with a medium chain triglyceride (MCT) vehicle that has a history of safe use in humans. This formulation was developed to 1) yield a presuspended product not requiring reconstitution of microspheres just prior to injection as with EQW, 2) be compatible with an easier-to-use pen device, 3) further reduce the initial exenatide release that appears to affect gastrointestinal tolerability.

**Materials and methods:** An in vitro assay performed at 37°C was used to compare the profiles of exenatide release from the microspheres when suspended in the different vehicles used for EQW and exenatide suspension. The pharmacokinetics (PK), safety, and efficacy of exenatide suspension were assessed in a Phase 2, two-cohort study. Subjects in Cohort 1 (30 healthy volunteers) received a single 10mg dose of exenatide suspension; subjects in Cohort 2 (35 subjects with T2DM (31% female, 52±11 y, WT 105±22 kg, HbA1c 8.0±0.9%, FPG 9.28±1.93 mmol/L, [mean±SD] treated with diet/exercise, metformin [MET], pioglitazone [PIO] or MET+PIO) were randomized to exenatide once weekly suspension (EQWS, 2 mg, N=23) or MCT vehicle control (N=12) for 12 weeks, with primary analyses performed at week 12.

**Results:** Using the in vitro method to compare release profiles, exenatide suspension demonstrated a blunted initial release compared to EQW but a similar overall release profile. Administration of a single 10-mg dose in healthy volunteers confirmed the in vitro profile; exenatide concentrations increased gradually over time, peaked at week 6–7, and approached lower level of detection after ~week 10. While initial early release was reduced relative to EQW (as observed during the first day post-dose), the extent and duration of exposure following a single dose of EQWS was similar to that of EQW. Nonparametric superpositioning simulations of the singledose data predicted similar steady-state concentrations (C<sub>ss</sub>) with 2 mg EQWS compared to 2 mg EQW. These simulations were confirmed with Cohort 2, where EQWS achieved mean C<sub>ss</sub> by ~week 8 that were in the range of C<sub>ss</sub> previously seen with EQW. At week 12, the LS mean (SE) change from baseline was significantly greater with EQWS than MCT for HbA1c (0.9 [0.2] vs. +0.1 [0.2]%,  $P=0.0013$ ) and

FPG (1.78 [0.55] vs. +0.44 [0.67] mmol/L,  $P=0.0035$ ) and was associated with weight loss (-1.4 [0.6] vs. -0.4 [0.7] kg,  $P=0.2285$ ). No unique safety findings were observed with EQWS relative to EQW.

**Conclusion:** EQWS was well tolerated, with improvements in glycaemic control and weight loss in patients with T2DM comparable to EQW. The similarities in the overall PK, safety, and efficacy profiles of EQWS compared to EQW confirm the appropriateness of the 2-mg weekly dose. These findings support the further development of this once-weekly presuspended product as a formulation that has the opportunity to improve the overall patient experience with their course of treatment by simplifying the drug preparation and administration process.

## 826

### Safety, tolerability, pharmacokinetics (PK) / pharmacodynamics (PD) of single escalating doses of semaglutide, a unique once weekly GLP-1 analogue, in healthy male subjects

C. Kapitza<sup>1</sup>, J. Lyng<sup>2</sup>, M. Düring<sup>2</sup>, C. Jensen<sup>2</sup>;

<sup>1</sup>Profil Institut, Neuss, Germany, <sup>2</sup>Novo Nordisk, Søborg, Denmark.

**Background and aims:** Medications administered once-weekly have the potential to improve patient compliance and thereby treatment outcomes. The aim of this first-in-man trial was to investigate safety, tolerability, PK and PD of the acylated, human GLP-1 analogue, semaglutide, aiming to establish the maximum tolerated single dose (MTSD).

**Materials and methods:** This was a randomised, double-blind, placebo-controlled, single-dose, dose escalation trial in healthy males. We randomised 56 subjects (active 6; placebo 2). Semaglutide doses: 0.625, 1.25, 2.5, 5, 10, 15 or 20 µg/kg. PK was assessed up to 19 days post-dose. Dosing day is Day 1. PD assessments included fasting plasma glucose (FPG), fasting insulin and glucagon (pre-dose, Day 2, Day 8), 14-h profiles of glucose, insulin and glucagon (Day 2), appetite ratings (Visual Analogue Scores, VAS) during a standard lunch meal, and energy intake (EI) during an *ad lib* dinner meal (pre-dose, Day 2, Day 8), and body weight (pre-dose and at multiple time points post-dose). MTSD was the dose at which less than 50% of subjects in a cohort had moderate or severe adverse events (AEs) related to trial product.

**Results:** MTSD was 15 µg/kg body weight (1.2 mg in an 80 kg subject). There were no serious AEs; all AEs were mild or moderate, and no subjects were withdrawn due to AEs. Most common AEs were nausea, dyspepsia and vomiting (10, 15, 20 µg/kg doses), headache, and decreased appetite (15, 20 µg/kg doses only). No treatment effect was observed on safety lab parameters (including calcitonin), vital signs, physical examination and ECG. No hypoglycaemia was reported. Plasma mean elimination half-life was 155–173 h (10, 15, 20 µg/kg doses). Median  $t_{max}$  was 16–20 h (10, 15, 20 µg/kg doses). Dose proportionality was shown for  $AUC_{0-48h}$ ,  $AUC_{0-168h}$ ,  $AUC_{0-inf}$  and  $C_{max}$  (10, 15, 20 µg/kg doses). There was an overall treatment effect on FPG ( $p=0.013$ ), fasting insulin ( $p<0.001$ ) and fasting glucagon ( $p=0.04$ ) on Day 2, and on fasting glucagon on Day 8 ( $p=0.011$ ). Further, there was an overall treatment effect on  $AUC_{0-14h \text{ post-dose}}$  for these parameters on Day 2 ( $p<0.001$ ,  $p<0.001$ ,  $p=0.038$ ). Mean VAS profiles indicated reduced hunger and prospective food consumption, and increased fullness and satiety, during the standard lunch meal at doses  $\geq 10$  µg/kg compared to placebo on Day 2, but not on Day 8 (statistical testing not done). Mean energy intake during the *ad lib* dinner meal on Days 2 and 8 appeared reduced at doses  $\geq 10$  µg/kg compared to placebo (statistical testing not done). Mean body weight decreased from baseline to follow-up (4 weeks post-dose) in most groups, incl. placebo, ranging from 0.9 kg with placebo to 1.2–2.8 kg for doses  $\geq 5$  µg/kg.

**Conclusion:** No safety concerns were identified; single s.c. doses of semaglutide were safe and well tolerated, and the PK profile was compatible with once-weekly administration. The observed effects on appetite, food intake and body weight may translate into significant clinical benefits with chronic treatment.

### Consistency of HbA<sub>1c</sub>-lowering effects of sitagliptin vs glipizide in patients with type 2 diabetes and chronic renal insufficiency across a variety of baseline characteristics

S. Engel, J.C. Arjona Ferreira, H. Guo, G. Golm, A.O. Johnson-Levonas, K. Kaufman, B.J. Goldstein; Merck Sharp & Dohme, Whitehouse Station, USA.

**Background/Synopsis:** In a 54-week, randomized, double-blind study conducted in patients with type 2 diabetes mellitus (T2DM) (n=423) with moderate or severe chronic kidney disease (CKD) (estimated glomerular filtration rate 30 to <50 or <30 mL/min/1.73 m<sup>2</sup>, respectively) sitagliptin (SITA) was previously shown to be non-inferior to glipizide (GLIP) in lowering A1C in the prespecified per protocol (PP) population (n=277).

**Methods:** Eligible patients for the study were ≥30 years of age with T2DM and moderate to severe CKD not on dialysis with A1C ≥7.0 and ≤9.0% on diet/exercise alone. Patients were randomized (1:1) to SITA or GLIP, and randomization was stratified by CKD status (moderate or severe). Doses of SITA for patients with moderate and severe CKD were 50 mg/d and 25 mg/d, respectively; the dose was adjusted downward (from 50 to 25 mg/d) if CKD status changed from moderate to severe during the study. The initial GLIP dose was 2.5 mg/d and could be titrated up to 10 mg BID as needed for glycemic control; the dose could also be reduced or interrupted to prevent hypoglycemia. The present analysis assessed the consistency of the A1C-lowering effects of SITA vs GLIP across prespecified subgroups of the PP population (baseline A1C, age, body mass index, diabetes duration, gender, race and severity of CKD).

**Results:** For the overall PP population, least squares (LS) mean changes from baseline in A1C were -0.76% (SITA) and -0.64% (GLIP), with a between-group difference (95% CI) of -0.11% (-0.29, 0.06). The between-group differences were generally consistent across the prespecified subgroups (Figure).

**Conclusion:** In patients with T2DM and CKD, treatment with SITA produced A1C reductions similar to those observed with GLIP, irrespective of baseline A1C, age, body mass index, diabetes duration, gender, race or severity of CKD.

### Islet-independent mechanisms contribute to glucose-lowering effect of sitagliptin after mixed meal and oral glucose in non-diabetic subjects

L. Ohlsson<sup>1</sup>, W. Alsalm<sup>1</sup>, R.D. Carr<sup>2</sup>, G. Pacini<sup>3</sup>, A. Mari<sup>4</sup>, B. Åhrén<sup>1</sup>; <sup>1</sup>Dept of Clinical Sciences, Lund, Sweden, <sup>2</sup>Merck A/S, Glostrup, Denmark, <sup>3</sup>ISIB-CNR Corso Stati Uniti, Biomedical Engineering, Padova, Italy, <sup>4</sup>Biomedical Engineering, Padua, Italy.

**Background and aims:** DPP-4 inhibitors improve glycemia by increasing the levels of glucagon-like peptide-1 (GLP-1) which stimulates insulin secretion and inhibits glucagon secretion at elevated glucose levels. We explored whether DPP-4 inhibition affects islet function at physiological glucose levels, and if DPP-4 inhibition differently affects islet GLP-1 and islet hormones after intake of mixed meal, oral glucose and oral lipid.

**Materials and methods:** Twelve healthy non-obese males ingested either a standardized mixed meal (560 kcal), glucose (2g/kg) or fat (olive oil; 0.9g/kg) together with DPP-4 inhibitor sitagliptin (100mg) or placebo. Blood samples were taken for analyses of glucose, intact GLP-1, insulin, C-peptide and glucagon; C-peptide deconvolution was used to estimate insulin secretory rate (ISR). Paracetamol test was used for determining gastric emptying. Suprabasal AUC were estimated.

**Results:** All three challenges increased plasma intact GLP-1 levels with augmented effects of sitagliptin. Fat was most potent in increasing GLP-1. Thus, the 120 min AUC being 863±123 (fat), 572±129 (glucose) and 220±80 pmol/l x min (meal) after placebo, increased to 2593±466 (fat), 1324±237 (glucose) and 502±113 pmol/l x min (meal) by sitagliptin (P<0.005 for all challenges). Fig. 1 shows that sitagliptin almost completely suppressed the raise in glucose after meal (AUC 46±16 vs 70±15 mmol/l x min; P=0.03). This was associated with reduced insulin levels (AUC 16±1 nmol/l x min vs 21±2 nmol/l x min P=0.02). ISR (20-60 min) was lower with sitagliptin than placebo (AUC 11±1 vs 15±2 nmol/min, m2, p=0.02), although sitagliptin increased ISR when compared at similar glucose levels. Also after glucose, sitagliptin prevented the increase in glucose with a reduction of insulin levels and ISR, similarly as after meal. After fat, glucose levels were reduced, insulin and ISR were not changed, and no additional effect of sitagliptin. Glucagon levels were increased after meal, reduced after glucose and not affected after fat, without statistically significant effects of sitagliptin. Gastric emptying was not altered by sitagliptin.

**Conclusion:** The increased glycemia after meal and glucose is prevented by sitagliptin without preceding increase in insulin, ISR, or reduction in glucagon in non-diabetic subjects, yet, when compared at identical glucose levels, insulin secretion is stimulated by sitagliptin. This suggests that extra-islet effects contribute to the glucose-lowering effect by sitagliptin, that an insulino-tropic effect of sitagliptin is manifested at as low glucose levels as 5 mmol/l. Also, the high GLP-1 after sitagliptin and fat does not affect islet hormone secretion at low glucose levels. Finally, fat is more powerful to raise GLP-1 than equicaloric glucose, and this effect is enhanced by sitagliptin.

**Conclusion:** The increased glycemia after meal and glucose is prevented by sitagliptin without preceding increase in insulin, ISR, or reduction in glucagon in non-diabetic subjects, yet, when compared at identical glucose levels, insulin secretion is stimulated by sitagliptin. This suggests that extra-islet effects contribute to the glucose-lowering effect by sitagliptin, that an insulino-tropic effect of sitagliptin is manifested at as low glucose levels as 5 mmol/l. Also, the high GLP-1 after sitagliptin and fat does not affect islet hormone secretion at low glucose levels. Finally, fat is more powerful to raise GLP-1 than equicaloric glucose, and this effect is enhanced by sitagliptin.

**Figure 1.** Plasma glucose and insulin levels and insulin secretory rate (ISR) calculated by deconvolution from C-peptide data after ingestion of mixed meal in non-diabetic healthy subjects with concomitant administration of sitagliptin (●-●) or placebo (○-○). Means±SEM are shown.

### Sitagliptin added to previously taken anti-diabetic agents on insulin-resistance and lipid profile: a two years study evaluation

P.D. Ragonesi<sup>1</sup>, P. Maffioli<sup>2</sup>, A.F.G. Cicero<sup>3</sup>, M.A. Ferraro<sup>4</sup>, A. Bonaventura<sup>2</sup>, L. Bianchi<sup>2</sup>, D. Romano<sup>2</sup>, E. Fogari<sup>2</sup>, G. Derosa<sup>2</sup>;

<sup>1</sup>Diabetes Care Unit, S. Carlo Hospital, Milano, Italy, <sup>2</sup>Internal Medicine and Therapeutics, University of Pavia, IRCCS Policlinico S. Matteo, Italy,

<sup>3</sup>"G. Descovich" Atherosclerosis Study Center, University of Bologna, Italy,

<sup>4</sup>Diabetologia, PST Gallico, Reggio Calabria, Italy.

**Background and aims:** Sitagliptin was the first DPP-4 inhibitor to be released for the use in the clinical practice; it is actually licensed at the recommended dose of 100 mg once daily either as monotherapy or in combination for the treatment of type diabetes mellitus in patients who have an inadequate glycaemic control. Sitagliptin already proved to be safe and effective in relatively short term studies, giving also a greater durability of β-cell compared to sulfonylureas. The aim of this study is to evaluate if the positive effects of sitagliptin on glycaemic control, insulin resistance and β-cell function are maintained also after 2 years of therapy, and if sitagliptin can be effective also in improving lipid profile.

**Materials and methods:** In this randomised, double-blind, placebo-controlled trial 205 type 2 diabetic patients in therapy with different anti-diabetic

drugs were randomised to add sitagliptin 100 mg once a day or placebo to their current therapy for 24 months. We evaluated at the baseline and after 6, 12, 18, and 24 months: body mass index (BMI), glycated hemoglobin (HbA<sub>1c</sub>), fasting plasma glucose (FPG), post-prandial glucose (PPG), fasting plasma insulin (FPI), homeostasis model assessment insulin resistance index (HOMA-IR), total cholesterol (TC), high density lipoprotein-cholesterol (HDL-C), low density lipoprotein-cholesterol (LDL-C), triglycerides (Tg). Continuous variables were compared by analysis of variance (ANOVA). Intervention effects were adjusted for additional potential confounders using analysis of covariance (ANCOVA). ANOVA was also used to assess the significance within and between groups. The statistical significance of the independent effects of treatments on the other variables was determined using ANCOVA. A 1-sample *t* test was used to compare values obtained before and after treatment administration; 2-sample *t* tests were used for between-group comparisons. For all statistical analyses, *p*<0.05 was considered statistically significant. **Results:** Sitagliptin, added to previously taken anti-diabetic agents, proved to be more effective in improving glycaemic profile, reducing HbA<sub>1c</sub> of -13.2% (*p*<0.01), FPG of -12.7% (*p*<0.05), PPG of -20.5% (*p*<0.01) compared to placebo. Regarding insulin resistance, sitagliptin decreased FPI of a -8.3% (*p*<0.05 vs placebo) and HOMA-IR of a -20.0% (*p*<0.01 vs placebo), confirming that what have been already reported in short term studies can be applied also after two years of treatment. Sitagliptin also reduced body weight of -4.3% (*p*<0.05 vs placebo). Our study also showed the positive effect of sitagliptin on lipid profile, in particular, sitagliptin decreased TC of a -13.3%, LDL-C of -20.4%, and Tg of -32.3%, and also increased HDL-C of +13.6% (*p*<0.05 vs placebo for all).

**Conclusion:** Sitagliptin proved to be effective on glycaemic profile, and insulin resistance even after 2 years of therapy, and to be effective in improving body weight, and lipid profile.

## 830

### Sitagliptin vs saxagliptin in decompensated type 2 diabetes mellitus patients

A. Asti, A. D'Alessandro, G. D'Alessandro, G. Fertuso, G. Perrone, S. Nardi, G. Maresca, P. Bellis; Loreto Mare Hospital, Naples, Italy.

**Background and aims:** Sitagliptin and saxagliptin are oral hypoglycemic agents inhibitors of DPP-4, indicated in the treatment of type 2 diabetes mellitus in combination with metformin, thiazolidinediones, sulfonylureas and insulin, in patients who have not achieved adequate glycemic control.

**Materials and methods:** In our study we enrolled 128 patients (67 F and 61 M), mean age 64.3 years (SD +/- 8.4), with an average duration of diabetes of 6.5 years (SD +/- 4.5), who, already taking metformin maximum dosage, presented themselves to our observation with glycated hemoglobin > 7.5% and fasting blood glucose > 140 mg / dl. At time 0' we have detected, moreover, weight, BMI, total cholesterol, HDL and LDL, triglycerides, transaminases and pancreatic amylase; patients were randomized to receive sitagliptin 100 mg/day (64 pts., 33 F and 31 M) or saxagliptin 5 mg/day (64 pts., 34 F and 30 M); follow-up was performed after 4 months with the revaluation of the same variables and adverse events.

**Results:** In sitagliptin group we observed a reduction in fasting glucose from 187 mg/dl to 138 mg/dl, glycated hemoglobin from 8.2% to 7.1%, weighing from 88 kg to 85.4 kg, BMI from 32.2 to 31, triglycerides from 192 mg/dl to 156 mg/dl; these reductions were statistically significant, while the reduction in total cholesterol and LDL cholesterol and a slight increase in HDL cholesterol did not reach statistical significance, there were no changes in pancreatic amylase. In saxagliptin group we observed a reduction in fasting glucose from 191 mg/dl to 160 mg/dl, glycated hemoglobin from 8.1% to 7.5%, body weight from 86.5 kg to 84.4 kg, BMI from 28 to 27.5, triglycerides from 178 mg/dl to 154 mg/dl, with statistical significance; also in this group the reduction of total cholesterol, LDL cholesterol did not reach statistical significance, HDL cholesterol appeared virtually unchanged, as well as pancreatic amylase. There were no suspension of therapy, adverse events appeared minor and temporary: in sitagliptin group we observed three cases of nausea and one case of nasopharyngitis, which resolved after ten days, in the saxagliptin group two cases of nausea and one case of headache which resolved quickly.

**Conclusion:** In conclusion, our observations highlight the almost identical efficacy of sitagliptin and saxagliptin in reducing blood glucose and glycated hemoglobin, with a favorable impact on weight and plasma lipids, in the presence of insignificant side effects: these data reinforce even more the idea that should think about this class of drugs as the next step in patients failing therapy with metformin.

## 831

### Combination therapy with low dose glimepiride and sitagliptin is effective for poorly controlled Japanese patients with type 2 diabetes

H. Ishii, M. Takei, S. Nisio, Y. Sato, S. Suzuki, M. Komatsu; Department Aging Medicine and Geriatrics, Shinshu University School of Medicine, Matsumoto, Japan.

**Background and aims:** The committee of Japan Association for Diabetes Education and Care has recommended that the dose of glimepiride should be decreased to at least 2 mg/day in case of combination therapy of sitagliptin and glimepiride to patients with higher doses of glimepiride in order to prevent unexpected hypoglycemia. Based on our preliminary clinical experiences, we suppose that the dose of glimepiride could be decreased to 1 mg/day without reducing its efficacy given 50 mg/day sitagliptin is added.

**Materials and methods:** To assess the efficacy and safety of the combination therapy with low dose glimepiride and sitagliptin for poorly controlled type 2 diabetes patients, we studied 34 patients with poorly controlled type 2 diabetes who are taking high dose of glimepiride at several hospitals or clinics in Nagano Prefecture, Japan. We decreased the dose of glimepiride to 1 mg/day and added 50mg/day of sitagliptin in all 34 patients. We divided 34 patients into three groups, the first one was low dose group (the dose of glimepiride was decreased from 2mg to 1mg), the second was moderate dose group (the dose of glimepiride was decreased from 3mg or 4mg to 1mg) and the third was high dose group (the dose of glimepiride was decreased from 6 mg to 1 mg). Other oral hypoglycemic agents except sulfonylureas were continued. We monthly checked HbA<sub>1c</sub>, casual plasma glucose, 1,5-AG, body weight and subjective symptoms in each group for 6 months.

**Results:** The mean age of patients was 68.2 years old and body mass index (BMI) was 25.8 kg/cm<sup>2</sup>. The average daily dose of glimepiride was 3.9mg. HbA<sub>1c</sub> was efficiently decreased during study period with combination therapy. (Before study; 8.3±0.6%, 4weeks; 7.7±0.5, 12weeks; 7.0±0.5, 24weeks; 7.0±0.5%). The average rate of decrease of HbA<sub>1c</sub> was 1.3% in low dose glimepiride group, 1.5% in moderate dose group and 1.2% in high dose group. Casual plasma glucose, 1,5-AG, BMI have not showed statistically significant changes. The combination therapy was well tolerated except that two patients temporarily had mild abdominal symptoms. Any hypoglycemic episodes did not occur during study period. The some of the patients (n=8) were followed up for a year without apparent deterioration of HbA<sub>1c</sub> (Figure 1).

**Conclusion:** In combination therapy with glimepiride and sitagliptin, reducing the dose of glimepiride to 1mg/day from any dose has showed a sufficient antihyperglycemic effect. This efficacy has lasted for at least 1 year. In the case of the combination therapy with glimepiride and sitagliptin for poorly controlled Japanese type 2 diabetes patients, we propose that it would be appropriate to reduce the dose of glimepiride to 1mg/day from the aspect of both the efficacy and the safety.

### Change of HbA<sub>1c</sub> for 12 months

## 832

# Efficacy and safety of exenatide once weekly vs sitagliptin in patients with type 2 diabetes mellitus: a post hoc analysis of pooled data from DURATION-2 and -4 clinical trials

K. Herrmann, J. Han, A. Meloni, M. Wintle, J. Malloy;  
Amylin Pharmaceuticals, Inc., San Diego, USA.

**Background and aims:** Therapies that leverage the glucagon-like peptide-1 (GLP-1) pathway are generally not associated with hypoglycaemia or weight gain and have been recommended for use in type 2 diabetes mellitus patients unable to achieve glycaemic control. This post hoc analysis compared the effects of 2 GLP-1-based therapies, exenatide once weekly (EQW), a GLP-1 receptor agonist, and sitagliptin (Sita), a dipeptidyl peptidase-4 inhibitor, on glucose control, body weight, tolerability, and safety.

**Materials and methods:** Data from DURATION-2 and -4 randomized, controlled, double-blind, clinical trials examining EQW and Sita on background therapies of diet and exercise and/or metformin for 26 weeks, were pooled and stratified by baseline HbA1c. Data were analyzed using the analysis of covariance (ANCOVA) model with the last observation carried forward (LOCF) method for missing data imputation.

**Results:** Baseline characteristics were 45% female, and mean age 52 years, weight 88 kg, and HbA1c 8.5%. Changes in HbA1c, fasting plasma glucose (FPG), and body weight, and the incidence of adverse events (AEs) including hypoglycaemia were examined. Significantly greater reductions in HbA1c and FPG occurred with EQW compared to Sita across all baseline strata of HbA1c, and significantly more patients in the EQW group attained the HbA1c targets of <7% and ≤6.5% compared to the Sita group (Table). Patients treated with EQW lost significantly more body weight than patients treated with Sita (LS mean [±SE] -2.16 [0.18] kg EQW; -0.84 [0.20] kg Sita;  $P<0.0001$ ). No major hypoglycaemia and a low incidence of minor hypoglycaemia were seen in both groups (1.7% EQW; 1.5% Sita). Serious AEs were observed with similar incidence in both groups (2.2% EQW; 2.4% Sita) and more AEs led to withdrawal in the EQW group compared to the Sita group (4.2% EQW; 1.8% Sita). The incidences of the most frequent AEs of nausea (18.6% EQW; 6.7% Sita) and diarrhea (14.7% EQW; 7.6% Sita) were higher in EQW compared to Sita patients. Incidence of these AEs decreased over time to reach similar levels by study end, with nausea (0.3% EQW; 0.0% Sita) and diarrhea (0.3% EQW; 0.7% Sita) having similar incidences by >24 to 26 weeks of treatment. A similarly low percent of patients discontinued due to nausea (0.5% EQW; 0.3% Sita) or diarrhea (0.7% EQW; 0.6% Sita).

**Conclusion:** In summary, significantly greater improvements in HbA1c, FPG, and body weight were observed in patients treated with EQW compared to Sita, regardless of baseline glycaemic control. No major hypoglycaemia and equally low rates of minor hypoglycaemia were observed across the treatment groups. EQW and Sita were both generally well tolerated.

\* $P<0.05$ , \*\* $P<0.005$ ;  $P$  value compares EQW with Sita.

Baseline data are mean (±SD); Δ from baseline and treatment difference data are LS mean (±SE).

Intent-to-treat population: EQW N=408; Sita N=329; n=2 patients had HbA1c <6.5% at baseline in the Sita group and were not included in the HbA1c subpopulations.

Clinical Trial Registration Number: NCT00637273; NCT00676338

## 833

# Optimisation of glycaemic control with the addition of sitagliptin in type 2 diabetic patients inadequately controlled with insulin

A. Marco, A. Luque, A. Vicente, I. Luque, E. Castro, B. Cánovas, J. Sastre, E. Maqueda, V. Peña, O. Llamazares, J. López;  
Department of Endocrinology and Nutrition, Complejo Hospitalario Toledo, Spain.

**Background and aims:** Several clinical trials have shown a reduction in HbA1c when DPP-IV inhibitors are added to insulin therapy in patients with type 2 diabetes.

**Objectives:** To evaluate the efficacy of sitagliptin when added to different regimens of insulin therapy in patients with type 2 diabetes.

**Materials and methods:** A total of 46 type 2 diabetic patients inadequately controlled (HbA1c >7%) with insulin (alone or in combination with other oral antidiabetic agents), were studied prospectively during 24 weeks once sitagliptin was added. Data regarding demographic characteristics, cardiovascular risk factors, diabetic complications and metabolic control parameters were collected. Comparison of categorical variables was performed using the chi-square test, paired t-test was used for comparison of continuous variables prior and after sitagliptin addition. Comparative differences were considered as statistically significant when  $p<0.05$  (SPSS v 16).

**Results:** 41,3% of the 46 patients studied were men, mean age 66,4±10,7 years, mean diabetes duration 17,3±11,8 years. 41,3 % received basal insulin, 47,8% premixed insulin, 4,3% bolus-basal and 6,5% basal plus regimen, 80,4% received metformin, 26,1% sulfonylureas, 13% repaglinide. 47,8% had retinopathy, 26,1% nephropathy, 30,4% polyneuropathy, 15,2% ischemic heart disease, 8,7% cerebrovascular disease, 8,7% peripheral vascular disease. 67,4% obesity 58,7% arterial hypertension, 65,2% hyperlipidemia, 69,6% antiagregant therapy. The addition of sitagliptin reduced significantly HbA1c from 8,3±0,8 to 7,3±0,9% ( $p<0.001$ ) and fasting plasma glucose (FPG) from 169,8±47,1 to 135,2±42,5 mg/dl ( $p<0.001$ ). When assessed by initial HbA1c stratum (<8%, 8–9%, >9%) the HbA1c reduction was 0,6%, 1,2% and 2,0% respectively. The proportion of patients with HbA1c <7% was 44,4% of the entire cohort (57,9%, 35% and 33% in each stratified group). The HbA1c response was similar in all insulin regimens and no differences were found considering the duration of the diabetes. There was no significant change from baseline in body weight (80,9±13,2 to 80,8±12,7), total daily insulin dose/body weight (0,51±0,3 to 0,52±0,3 UI/kg), systolic pressure (142,4±20,7 to 139,0±16 mmHg), diastolic pressure (76,9±12,3 to 76,3±9,5 mmHg) and lipid parameters (LDL cholesterol 94,23±31,2 to 81,53±18,4 mg/dl).

**Conclusion:** The addition of sitagliptin to ongoing insulin therapy provided significant reduction in HbA1c without weight gain after 24 weeks of treatment and enabled a great proportion of patients to achieve the HbA1c target, even in patients with a long diabetes duration.

## 834

# Sitagliptin provides similar glycaemic improvement with less hypoglycaemia in the elderly with type 2 diabetes mellitus compared to sulphonylurea

R. Shankar, S.S. Engel, L. Xu, G.T. Golm, M.J. Davies, K.D. Kaufman, B.J. Goldstein;  
Merck Sharp & Dohme, Whitehouse Station, USA.

**Background and aims:** The global burden of type 2 diabetes mellitus (T2DM) in the elderly (≥65 years), who present unique therapeutic challenges due to comorbidities, is estimated to increase by 134% in 2030 compared to 2000. Sulphonylurea use is associated with greater risk for hypoglycaemia in the elderly and its use increases with age. Hypoglycaemia and its consequences may be more pronounced in the elderly. Sitagliptin, a DPP-4 inhibitor, improves glycaemic control, with a low risk of hypoglycaemia when used alone or with metformin. The present *post hoc* analyses compared the efficacy and safety of sitagliptin versus sulphonylurea in elderly patients with T2DM.

**Methods:** The data of patients ≥65 years of age were pooled from 3 double-blind studies to compare the effects of sitagliptin (100 mg/day) or sulphonylurea (in titrated doses) on change from baseline in HbA<sub>1c</sub>, fasting plasma glucose (FPG), and body weight and incidence of symptomatic hypoglycaemia. Patients on diet alone or metformin were randomized to sitagliptin or glipizide for 104 weeks (Studies 1-2) or glimepiride for 30 weeks (Study 3); hence, the analyses included 373 elderly patients who completed trials through 30 weeks.

**Results:** Both HbA<sub>1c</sub> and FPG decreased with sitagliptin and sulphonylurea, with no statistical difference between treatments (Table). The proportion of

patients with an  $\text{HbA}_{1c} < 6.5\%$  was similar between treatments. Significantly lower incidence of symptomatic hypoglycaemia was observed with sitagliptin relative to sulphonylurea. Body weight decreased significantly from baseline with sitagliptin. Significantly more patients on sitagliptin than sulphonylurea achieved the composite endpoint of  $>0.5\%$   $\text{HbA}_{1c}$  reduction with no hypoglycaemia or body weight gain at 30 weeks.

**Conclusion:** Sitagliptin provided similar glycaemic efficacy, with less hypoglycaemia and with body weight loss compared to sulphonylurea in elderly patients, suggesting that sitagliptin is an effective and well-tolerated treatment option for elderly patients with T2DM.

### China type 2 diabetes treatment status survey of treatment pattern of oral drugs users (China DiaSTAGE)

L. Ji<sup>1</sup>, J. Lu<sup>2</sup>, J. Weng<sup>3</sup>, W. Jia<sup>4</sup>, H. Tian<sup>5</sup>, D. Zhu<sup>6</sup>, X. Xing<sup>7</sup>, L. Guo<sup>8</sup>,  
<sup>1</sup>Peking University People's Hospital, <sup>2</sup>Chinese PLA General Hospital, Beijing, <sup>3</sup>The Third Affiliated Hospital Of Sun Yat-sen University, Guangzhou, <sup>4</sup>Shanghai 6th Hospital, Shanghai, <sup>5</sup>West China Hospital, Chengdu, <sup>6</sup>Nanjing Drum Tower Hospital, Jiangsu, <sup>7</sup>Peking Union Medical College Hospital, Beijing, <sup>8</sup>Beijing Hospital, Beijing, China.

**Background and aims:** Diabetes is a serious threat to public health. It is very important and cost effective to implement diabetes management guidelines strategically and systematically. This study provides valuable basic data of oral antidiabetic drug (OAD) therapy status for type 2 diabetes (T2D) patients in clinical practice which can contribute to future popularisation and implementation of Chinese T2D management guidelines.

**Materials and methods:** The China DiaSTAGE, a non-interventional, cross-sectional study, was conducted at 103 hospitals across the country. The study included outpatients with T2D who have received treatment for T2D for  $\geq 6$  months, have visited the investigated hospital for  $\geq 3$  months, have taken OADs (monotherapy or combined therapy) for  $\geq 3$  months; and who completed the study questionnaire. The first 5 patients who fulfilled the inclusion criteria were enrolled every day. Demography, medical history, current antidiabetic treatment regimen, treatment alteration within the last year, status of glycaemic control, frequency of hypoglycaemia within last month, presence of oedema and change in body weight were studied.

**Results:** The study included 9872 Chinese T2D patients of which 50.9% were males. Mean age was  $60.0 \pm 11.3$  years and BMI  $24.6 \pm 3.2 \text{ kg/m}^2$ . Medical history included hypertension (52.2%), dyslipidaemia (43.5%), coronary heart disease (16.7%), diabetic neuropathy (15.6%), diabetic retinopathy (13.9%), diabetic nephropathy (6.7%), stroke (6.0%) and diabetic foot (3.1%). Physician suggested diet control and exercise as a treatment regimen in 87.0% and 77.8% patients, respectively. Use of insulin secretagogues (70.2%), such as sulphonylureas (SU; 42.7%) or glinides (27.5%), was most common followed by metformin (53.7%), glucosidase inhibitors (35.9%), thiazolidinediones (17.2%) and DPP-IV inhibitors (0.8%). Dual-drug combination therapy was more common (45.4%) than monotherapy (35.8%) and combination therapy of  $\geq 3$  drugs (17.0%). Metformin/SU was the most common dual-drug com-

bination. Among monotherapies, 45.6% patients received insulin secretagogues (SU or glinides) and 30% received metformin. Within the past year, 31.9% of patients altered their treatment regimen, mostly once (70.6%), citing poor effectiveness as the main reason. Glycaemic targets of  $\text{FPG} \leq 7 \text{ mmol/L}$ ,  $\text{PPG} \leq 10 \text{ mmol/L}$ ,  $\text{HbA}_{1c} \leq 6.5\%$  and  $\text{HbA}_{1c} \leq 7\%$  were achieved in 51.4%, 53.5%, 27.8% and 39.6% patients, respectively. The last reported mean  $\text{HbA}_{1c}$  was  $7.22 \pm 1.49\%$ . Presence of hypoglycaemia within last month was reported by 14% patients. Overall, 3% patients reported severe hypoglycaemia, 5% reported oedema and 8.2% reported weight gain ( $2.8 \pm 2.6 \text{ kg}$ ).

**Conclusion:** In China, insulin secretagogues are the first choice of OADs which may be the reason for observed high incidence of hypoglycaemia and maybe limit glucose control. Poor effectiveness is reported as the main reason for the alteration of treatment regimen. These observations may serve as guidance for future diabetes management guidelines in China.

### Glucose control and oral hypoglycaemic agents in eight regions across China

T. Chen<sup>1</sup>, H. Tian<sup>1</sup>, L. Ji<sup>2</sup>, China DiaSTAGE group;

<sup>1</sup>Department of Endocrinology and Metabolism, West China Hospital of Sichuan University, Chengdu, <sup>2</sup>Department of Endocrinology and Metabolism, Peking University People's Hospital, Beijing, China.

**Background and aims:** Due to economic factors, physician's preference and so on, the regimens of OHA might be different in different region of China, which might affect blood glucose (BG) control. To better address these issues, the Chinese Diabetes Association conducted a survey on the OHA regimens and its association with BG control in different regions across China.

**Materials and methods:** In this multi-center, non-intervention, cross-sectional survey, 10 000 type 2 diabetes patients at more than 100 medical centers were investigated. Oral hypoglycemic regimens (OHA, e. g. the types of drugs, the combination of drugs), and the frequencies of hypoglycemia and severe hypoglycemia etc were evaluated. FBG less than  $7 \text{ mmol/L}$ , 2hPBG less than  $10 \text{ mmol/L}$  and  $\text{HbA}_{1c}$  less than 7% were defined as good BG control. The regions were divided into eight conventionally, that is, Northwest (Gansu), Northeast (Liaoning, Jilin, Heilongjiang), Northern coastal region (Beijing, Tianjin, Shandong), Middle reaches of the Yellow River (Shaanxi), Eastern coastal region (Shanghai, Jiangsu, Zhejiang), Middle reaches of the Yangtze River (Hunan, Hubei, Jiangxi), Southwest (Sichuan, Chongqing, Guizhou, Guangxi), and Southern coastal areas (Fujian, Guangdong and Hainan).

**Results:** 1. The levels of FBG, 2hPBG and  $\text{HbA}_{1c}$  of patients from Southern coast, Northern coast, East coast and Middle reaches of the Yangtze River, were lower than those from the Middle reaches of the Yellow River, Northeast and Northwest regions. The good control rates FBG, 2hPBG and  $\text{HbA}_{1c}$  were ranged from 49.9% to 56.5%, from 50.8 to 59.2%, and from 43.6 to 50.6% respectively. While in Northwest, Northeast and Middle Yellow River regions, the rates ranged from 26.8% to 36.0%, from 24.7% to 46.3%, from 20.1% to 35.8% respectively. Good control rates of FBG and 2hPBG in Southwest were about 50%, but that of  $\text{HbA}_{1c}$  was only 33.7%. 2. The incidence of hypoglycemia and severe hypoglycemia were significantly higher in Middle reaches of the Yellow River. 3. Further analysis indicated that in regions with bad BG control, the rates of diet and/or physical exercise were relatively lower, the rates of OHA combination therapy were relatively infrequent, the rates of sulphonylureas, glinides, glucosidase inhibitor medication were lower, and the rates of other drugs (traditional Chinese medicine, the mixture of Chinese and Western medicine, fixed formula compound preparation) were higher.

**Conclusion:** The overall status of blood glucose control in China was not optimistic, and which were even worse in regions of Northwest, Northeast and Middle reaches of the Yellow River. Relatively poor diet and physical exercise and the different choices of OHA regimen were potential contributing factors. Clinical practitioners should pay more attention to such issues in the future.

## PS 066 DPP-4 inhibitors: clinical studies

### Efficacy and safety of saxagliptin (SAXA) in patients with type 2 diabetes and a history of cardiovascular disease

W. Cook<sup>1</sup>, B. Bryzinski<sup>2</sup>, J. Slater<sup>3</sup>, M. Donovan<sup>3</sup>, E. Allen<sup>3</sup>;<sup>1</sup>Medical Affairs, AstraZeneca, Wilmington, DE, USA, <sup>2</sup>Research & Development, AstraZeneca, Wilmington, <sup>3</sup>Bristol-Myers Squibb, Princeton, Bristol-Myers Squibb, Princeton, USA

**Background and aims:** To determine the efficacy and safety of SAXA in patients (pts) with T2D and a history of CV disease, we conducted a subgroup analysis of pooled data from 5 phase 3 placebo-controlled 24-week studies: 2 studies of SAXA as monotherapy in drug-naïve pts and 1 study each of SAXA as add-on therapy to metformin, glyburide, or a thiazolidinedione.

**Materials and methods:** Pooled efficacy (glycated hemoglobin [HbA<sub>1c</sub>], fasting plasma glucose [FPG], 120-min postprandial glucose [PPG]) and safety data (adverse events [AEs], body weight) for SAXA 5 mg and placebo were analyzed in pts with a history of CV disease (previous event or diagnosis of CV disease) or no history of CV disease using analysis of covariance.

**Results:** In total, 882 pts received SAXA 5 mg and 799 received placebo. At week 24, improvements in HbA<sub>1c</sub>, FPG, and PPG were greater and more pts achieved a glycemic target (HbA<sub>1c</sub> <7%) with SAXA compared with placebo irrespective of CV disease history. There were no important treatment-by-subgroup interactions for SAXA. Differences in adjusted mean±SE reductions in HbA<sub>1c</sub> with SAXA were greater than placebo in pts with a history of CV disease (−0.64±0.14 [95% CI, −0.90 to −0.38]; Table). Similar results were seen in pts without CV disease (−0.68±0.05 [95% CI, −0.78 to −0.58]). Differences in adjusted mean change in body weight with SAXA vs placebo were +0.7 kg (CV disease history) and +0.5 kg (no CV disease history). The incidences of ≥1 AE with SAXA vs placebo were 70.3% vs 72.2%, respectively, in pts with CV disease history and 72.3% vs 70.2% in those without, and the incidences of ≥1 treatment-related AE were 18.9% vs 14.4% and 18.7% vs 17.0%, respectively. The rates of discontinuations for AEs for SAXA vs placebo were 2.7% vs 2.1% in those with and 3.4% vs 1.7% in those without CV disease history. Serious AEs were reported by 4.5% of SAXA-treated pts vs 7.2% of those receiving placebo in pts with and 3.1% vs 2.9% in pts without CV disease history. Two pts without CV disease history (n=1, SAXA 5 mg; n=1, placebo) experienced ≥1 treatment-related serious AE. There were 2 deaths in pts receiving placebo, 1 in each subgroup. The incidence of all reported hypoglycemic AEs was similar in pts with and without CV disease history (7.2% with SAXA vs 6.2% with placebo and 7.8% vs 6.7%, respectively). Confirmed hypoglycemia (fingerstick glucose ≤50 mg/dL and associated symptoms) was reported by 0 pts treated with SAXA and 2.1% of pts receiving placebo in subgroups with CV disease history and 0.5% vs 0.1%, respectively in those without CV disease history.

**Conclusion:** In this pooled analysis of phase 3 placebo-controlled trials, SAXA 5 mg was similarly effective with an adverse event rate similar to placebo in pts with T2D regardless of CV disease history. Glycemic efficacy at 24 weeks with SAXA 5 mg in patients with and without CV disease history

### Efficacy and safety of saxagliptin (SAXA) in patients with type 2 diabetes stratified by cardiovascular risk factors

E. Allen<sup>1</sup>, J. Slater<sup>1</sup>, B. Bryzinski<sup>2</sup>, M. Donovan<sup>3</sup>, W. Cook<sup>4</sup>;<sup>1</sup>Medical Affairs, Bristol-Myers Squibb, Princeton, <sup>2</sup>Research & Development, AstraZeneca, Wilmington, <sup>3</sup>Biostatistics, Bristol-Myers Squibb, Princeton, <sup>4</sup>Medical Affairs, AstraZeneca, Wilmington, USA.

**Background and aims:** Patients (pts) with T2D have elevated risk of CV disease, are likely to have other comorbidities, and receive concomitant medications for those conditions. To determine if there is a difference in SAXA efficacy in T2D pts with vs without hypertension (HTN), statin use, or multiple CV risk factors, we conducted a subgroup analysis of pooled data from 5 phase 3 placebo (PBO)-controlled 24-week studies: 2 studies of SAXA as monotherapy in drug-naïve pts and 1 study each of SAXA as add-on therapy to metformin, glyburide, or a thiazolidinedione.

**Materials and methods:** Pooled efficacy (glycated hemoglobin [HbA<sub>1c</sub>], fasting plasma glucose [FPG], 120-min postprandial glucose [PPG]) and safety data (adverse events [AEs], serious AEs, hypoglycemia, body weight) for SAXA 5 mg and PBO were analyzed in subgroups defined by the presence of HTN/no HTN, statin use/no statin use, and multiple (≥2 or 0-1) CV risk factors (HTN, dyslipidemia, smoking, family history of CV disease) using analysis of covariance.

**Results:** In total, 882 pts received SAXA 5 mg and 799 received PBO. At week 24, improvements in glycemic control were greater with SAXA vs PBO in all subgroups (Table). There were no important treatment-by-subgroup interactions for SAXA (Table). In all subgroups, glycemic target of HbA<sub>1c</sub> <7% was achieved by more pts treated with SAXA vs PBO (difference in proportions vs PBO [95% CI], using Mantel-Haenszel rate difference estimate: HTN, 16.7% [10.6%-22.7%]; no HTN, 16.3% [9.6%-23.0%]; statin use, 18.2% [9.0%-27.3%]; no statin use, 15.8% [10.6%-20.9%]; ≥2 CV risk factors, 16.7% [10.4%-23.0%]; 0-1 CV risk factor, 16.2% [9.8%-22.6%]). Overall incidence of ≥1 AE with SAXA vs PBO was as follows in each subgroup: 71.0% vs 72.5% (HTN), 73.7% vs 67.9% (no HTN), 77.1% vs 75.5% (statin use), 70.7% vs 68.8% (no statin use), 75.4% vs 73.0% (≥2 CV risk factors), and 68.6% vs 67.9% (0-1 CV risk factor). Incidence of ≥1 serious AE was similar for SAXA vs PBO in subgroups with HTN (3.6% vs 4.5%), no HTN (3.1% vs 2.0%), with statin use (4.7% vs 3.8%), no statin use (3.0% vs 3.2%), with ≥2 CV risk factors

(3.8% vs 4.1%), and with 0–1 CV risk factor (2.9% vs 2.6%). There were no deaths in the SAXA groups and 2 deaths in the PBO group (HTN subgroup [n=2]; no statin use subgroup [n=2];  $\geq 2$  CV risk factors subgroup [n=2]). Incidences of all reported hypoglycemia ranged from 6.7%–11.2% with SAXA vs 6.3%–7.2% with PBO. Symptomatic confirmed hypoglycemia (glucose  $\leq 50$  mg/dL) was  $<1\%$  in all subgroups. Differences in adjusted mean change in body weight with SAXA vs PBO ranged from 0.4–0.7 kg.

**Conclusion:** SAXA 5 mg was effective with an AE rate profile similar to PBO in pts with T2D irrespective of concomitant HTN, statin use, or number of CV risk factors. Concomitant statin use was not associated with a lower HbA<sub>1c</sub> reduction. Glycemic efficacy at 24 weeks with SAXA 5 mg in 5 pooled studies.

### An integrated, multi study analysis of alogliptin safety

M. Hisada, M. Munsaka, J. Streit, N. Smith;  
Takeda Global Research & Development Center, Inc., Deerfield, USA.

**Background and aims:** Alogliptin (ALO) is a selective inhibitor of dipeptidyl peptidase-4 for the treatment of type 2 diabetes mellitus. We performed an integrated analysis of controlled phase 2 and 3 studies to evaluate the safety of ALO.

**Materials and methods:** Subjects who received at least one dose of study drug were included in the analysis of 11 pooled studies and were categorized by treatment assignment as ALO (n=4162) or comparator (including placebo) (Com; n=1855).

**Results:** Demographics were similar between groups. The majority of subjects were aged  $<65$  years (ALO, 78%; Com, 72%), female (both 51%), and white (ALO, 73%; Com, 71%), with BMI  $\geq 30$  kg/m<sup>2</sup> (ALO, 55%; Com, 53%), and had mild renal impairment (MDRD: eGFR  $\geq 60$  -  $< 90$  mL/min/1.73 m<sup>2</sup> criteria) (both 68%); mean baseline A1c was 8.3% (both). A lower proportion of ALO vs Com subjects required hyperglycemic rescue (11% vs 21%). Similar proportions of subjects in both groups experienced  $\geq 1$  adverse event (AE) (ALO, 65%; Com, 64%). The only AEs occurring at  $\geq 5\%$  in either group were urinary tract infection (ALO, 4.9%; Com 5.2%) and headache (both 5.0%). Serious AEs were reported by 4% of subjects in each group and deaths attributed to AEs occurred at 0.1% for both groups. A lower proportion of ALO vs Com subjects experienced a major adverse cardiovascular event (MACE: 0.3% ALO vs 0.5% Com); the hazard ratio for MACE for ALO vs Com was 0.65 (upper bound of 1-sided 97.5% CI = 1.41). Incidence of hepatic enzyme elevation (ALO, 0.4%; Com, 0.3%) was low in both groups. Rare events of rash and pruritus were reported with ALO. Four subjects in the ALO group (0.1%) reported acute pancreatitis as compared to 0 in the Com group.

**Conclusion:** This analysis suggests that ALO is safe and well tolerated with a safety profile similar to that of other DPP-4 inhibitors.

### Similar glucose control over 52 weeks with alogliptin vs glipizide in older, mildly hyperglycaemic patients with type 2 diabetes

P. Fleck<sup>1</sup>, C. Wilson<sup>1</sup>, J. Rosenstock<sup>2</sup>;

<sup>1</sup>Takeda Global Research & Development Center, Inc., Deerfield, <sup>2</sup>Dallas Diabetes and Endocrine Center, Dallas, USA.

**Background and aims:** Most studies on the effects of DPP-4 inhibitors in older people with type 2 diabetes mellitus (T2DM) have been post-hoc analyses. This study prospectively evaluated the efficacy and safety of alogliptin (ALO) vs glipizide (GLIP) in a well-defined older population with T2DM over 1 year of treatment.

**Materials and methods:** Eligible subjects with T2DM had to be aged 6590 years who had failed diet/exercise therapy alone (A1c 6.5% - 9.0%) or were inadequately controlled despite oral antidiabetic monotherapy (A1c 6.5% - 8.0%). The study comprised a screening period (2 wks), treatment period (52 wks), and visits at end-of-study (or early termination) and follow-up (2 wks later). Those on oral antidiabetic monotherapy underwent a washout period (4 wks) prior to randomization. Subjects (441 total) were randomized to once-daily ALO 25 mg (n=222) or GLIP 5 mg titrated to 10 mg, if needed (n=219). Hypoglycemic episodes were identified via stringent predefined criteria and procedures.

**Results:** Baseline characteristics were similar between the groups (mean A1c, 7.5%; diabetes duration, 6.1 years; BMI, 29.8; weight, 78.7 kg). In the primary analysis, A1c least squares (LS) mean changes from baseline to week 52 were 0.14% with ALO and 0.09% with GLIP, demonstrating noninferiority of ALO relative to GLIP (LS mean difference = -0.05%; 1-sided 97.5% confidence interval [CI]: infinity, 0.13%). More substantial A1c reductions were observed among subjects who completed the study: 0.42% with ALO and -0.33% with GLIP, with noninferiority again confirmed (LS mean difference = 0.09%; 1-sided 97.5% CI: infinity, 0.07%). A1c decreases were greater among subjects with baseline A1c  $\geq 8.0\%$  (0.32% with ALO and 0.34% with GLIP) vs those whose baseline A1c was  $<8.0\%$  (0.07 and -0.04%, respectively). Overall, alogliptin was safe and well tolerated. Hypoglycemic episodes were notably less frequent with ALO (5.4% of subjects reporting 31 episodes) vs GLIP (26.0% of subjects reporting 232 episodes). Most episodes were mild or moderate (BG  $<70$  mg/dL); severe hypoglycemia (BG  $<70$  mg/dL, requiring assistance) occurred in 3 subjects (all GLIP). ALO also resulted in significant weight decrease vs GLIP (0.62 vs 0.60 kg, respectively, at week 52;  $P<0.001$ ).

**Conclusion:** Alogliptin maintains comparable glucose control to glipizide but with substantially lower risk of hypoglycemia and without weight gain over 1 year of treatment in older patients with T2DM.

### Alogliptin plus metformin combination therapy vs alogliptin or metformin monotherapy for type 2 diabetes mellitus

R. Pratley<sup>1</sup>, C. Wilson<sup>2</sup>, P. Fleck<sup>2</sup>;

<sup>1</sup>Florida Hospital Diabetes and Translational Research Institute and Sanford|Burnham Institute, Orlando, <sup>2</sup>Takeda Global Research & Development Center, Inc., Deerfield, USA.

**Background and aims:** The efficacy and safety of alogliptin (ALO) plus metformin combination therapy (ALO+MET) in doses of 12.5/500 and 12.5/1000 mg BID vs monotherapy with ALO 12.5 mg BID (ALO12.5) or MET 500 or 1000 mg BID (MET500 or MET1000) was evaluated in a 7-arm study of 784 subjects with type 2 diabetes mellitus inadequately controlled with diet and exercise alone; 2 arms, placebo and ALO 25 mg QD, were included for the purposes of secondary analyses.

**Materials and methods:** In the primary efficacy analysis, the 2 combination therapy regimens were compared with their monotherapy regimens (ALO+MET 12.5/500 vs ALO12.5 and MET500, and ALO+MET 12.5/1000 vs ALO12.5 and MET1000).

**Results:** The majority of subjects were white (72%), women (52%), mean age of 54 years, body mass index of 31, diabetes duration of 4 years, and baseline A1c of 8.4%. Reductions in A1c at week 26 (primary endpoint) were 1.22% and 1.55% with ALO+MET 12.5/500 and 12.5/1000, vs 0.56%, 0.65%, and 1.11% with ALO12.5, MET500, and MET1000 ( $P<0.001$  for all comparisons). Significantly more subjects achieved A1c  $<7\%$  with ALO+MET (47.1% and 59.5% with 12.5/500 and 12.5/1000) vs monotherapy with ALO12.5, MET500, or MET1000 (20.2%, 27.2%, and 34.3%) ( $P<0.01$  for all comparisons). Reductions in FPG were -31.7 and 45.9 mg/dL with ALO+MET

12.5/500 and 12.5/1000, vs 9.7, 11.5, and 31.9 mg/dL with ALO12.5, MET500, and MET1000 ( $P<0.05$  for all comparisons). Significantly fewer ALO+MET subjects were rescued for hyperglycemia: 12.3% and 2.6% with 12.5/500 and 12.5/1000, vs 17.3%, 22.9%, 10.8% with ALO12.5, MET500, and MET1000 ( $P<0.05$  for all comparisons). Greater reductions in proinsulin/insulin ratios and increases in HOMA-BCF (beta cell function) with ALO+MET vs ALO or MET monotherapy were observed. Modest weight decreases were observed with ALO+MET and MET, while ALO monotherapy was weight neutral. ALO and MET alone demonstrated the expected safety profiles, and the combination doses were well tolerated, having safety profiles similar to that of the monotherapy regimens. Overall, few subjects reported hypoglycemic events.

**Conclusion:** In summary, ALO+MET combination therapy provided significantly better glycemic control than ALO or MET monotherapy, with a safety profile consistent with its individual components.

### Effect of alogliptin in combination with pioglitazone on glycaemic control by baseline HbA<sub>1c</sub>

C. Wilson, P. Fleck;

Takeda Global Research & Development Center, Inc., Deerfield, USA.

**Background and aims:** This phase 3, randomised, double-blind, placebo-controlled, 12-treatment arm study assessed the efficacy and safety of alogliptin (ALO) alone or combined with pioglitazone (PIO) in patients with type 2 diabetes on metformin with inadequate glycemic control.

**Materials and methods:** Treatment arms included ALO alone at doses of 12.5 or 25 mg QD; PIO alone at doses of 15, 30, or 45 mg QD; combinations of each ALO dose with each PIO dose; and a placebo arm. The primary analysis compared PIO alone (doses pooled; 387) with ALO 12.5 mg + any dose of PIO ( $n=390$ ) or ALO 25 mg + any dose of PIO ( $n=390$ ). The change from baseline A1C at week 26 by baseline A1C was determined using 2 subgroups:  $<8.5\%$  and  $\geq 8.5\%$ .

**Results:** Subjects in the combination groups achieved significantly larger decreases from baseline in A1C levels at week 26 compared with subjects in the PIO alone group ( $P<0.001$ ); greater reductions were observed for subjects with higher baseline A1C levels. Similarly, the majority of the ALO + PIO arms exhibited a statistically significant decrease in A1C levels at week 26 compared with corresponding doses of ALO alone and PIO alone ( $P<0.05$ ), regardless of baseline A1C; however, decreases were larger in subjects with higher baseline A1C levels (Figure). The incidence of adverse events (AEs) was similar across all 12 arms, ranging from 54.3% (placebo) to 69.2% (ALO 25 mg + PIO 15 mg); serious AEs ranged from 0.8% (PIO 15 mg and ALO 25 mg + PIO 15 mg) to 7.8% (PIO 45 mg). Few subjects discontinued due to an AE, with the most occurring in the PIO 45 mg arm (7/129; 5.4%). Overall, few subjects reported hypoglycemic events.

**Conclusion:** In conclusion, ALO + PIO was significantly more effective than either monotherapy, with greater reductions being achieved in patients with higher baseline A1C levels in all active treatment groups.

### Differential effects of vildagliptin and glimepiride on the glucose fluctuation in patients with type 2 diabetes mellitus assessed with continuous glucose monitoring

Y.-L. He<sup>1</sup>, G. Foteinos<sup>1</sup>, S. Neelakantham<sup>2</sup>, D. Mattapalli<sup>2</sup>, K. Kulmatycki<sup>1</sup>, T. Forst<sup>3</sup>, A. Taylor<sup>1</sup>;

<sup>1</sup>Translational Science, Novartis, Cambridge, USA, <sup>2</sup>Novartis, Hyderabad, India, <sup>3</sup>Institute for Clinical Research and Development, Mainz, Germany.

**Background and aims:** Vildagliptin is a potent, selective and orally active inhibitor of dipeptidylpeptidase-IV (DPP-4), which is approved for the treatment of type 2 diabetes mellitus (T2DM). Vildagliptin has demonstrated a low risk of hypoglycaemia, a major safety concern with glucose lowering therapy. Although it is well known that hyperglycaemia is closely related to the development of macro- and microvascular complications of diabetes, an increasing number of studies have shown that glucose fluctuation or variability is more important than chronic sustained hyperglycaemia in generating oxidative stress and contributing to the diabetes complications. The objective of this study was to assess whether or not there is a difference in the effects of vildagliptin and glimepiride on glucose fluctuation in patients with T2DM using continuous glucose monitoring (CGM).

**Materials and methods:** This was an open-label, randomised, crossover study in patients with T2DM. A total of 24 patients (Age:  $56.6 \pm 5.76$  yrs, baseline HbA<sub>1c</sub>:  $7.55 \pm 0.50\%$ ) were enrolled and all completed the study. Each patient received two 5-day treatments (vildagliptin 50 mg bid or glimepiride 2 mg qd) in a cross-over manner with ~14 day washout period. Blood glucose concentrations were measured using a CGM device during baseline and 5 day treatment, and glucose fluctuation parameters [standard deviation (SD) of the rate of change, interquartile range (IQR), rate of change in the median curve (RCMC), mean amplitude of glucose excursion (MAGE)] were estimated at baseline and day 5. The relationship between the ratio of urinary excretion rate of 8-iso-prostaglandin F<sub>2a</sub> and creatinine and MAGE was also explored.

**Results:** Both vildagliptin and glimepiride reduced postprandial glucose levels by ~15%, based on both CGM data and plasma glucose concentrations, which is consistent with the magnitude of effects for both agents reported in previous studies. When comparing the effects of vildagliptin and glimepiride on the glucose fluctuation, vildagliptin showed 26% lower RCMC ( $P = 0.0082$ ), 19% lower MAGE ( $P = 0.1076$ ) and 23% lower IQR ( $P = 0.0462$ ) than glimepiride. It is interesting to note that vildagliptin led to statistically significant lower RCMC and IQR, however, the reduction in MAGE did not reach statistical significance. MAGE is a parameter derived from the glucose profiles and the variability of MAGE parameter tends to be higher due to the derivative nature. The inability to demonstrate a statistically significant difference could be attributed to the small sample size. There was no apparent association between the ratio of 8isoprostaglandin F<sub>2a</sub> and creatinine and MAGE detected. Both vildagliptin and glimepiride were generally safe and well tolerated. Only one subject receiving treatment with glimepiride had a symptomatic hypoglycaemia event which required treatment.

**Conclusion:** Vildagliptin treatment is associated with significant lower glucose fluctuation than Glimepiride in patients with T2DM. These results suggest that vildagliptin may have the potential to offer long term beneficial effects for patients with T2DM in preventing the development of macro- or microvascular complications of diabetes.

### Comparison of glycaemic variability in patients with type 2 diabetes given sitagliptin or voglibose: a continuous glucose monitoring (CGM)-based pilot study

C. Seo, M. Sakamoto, R. Nishimura, D. Tsujino, K. Andou, A. Morimoto, K. Utsunomiya;

Diabetes, Metabolism and Endocrinology, Jikei University School of Medicine, Minato-ku, Nishishinbashi, Tokyo, Japan.

**Background and aims:** To compare glycemic variability in patients with type 2 diabetes given sitagliptin (S) or voglibose (V).

**Methods:** The study included a total of 15 type 2 diabetic patients aged 20 years old or older but younger than 80 years of age. These patients were randomly allocated to S 50 mg/day or V 0.9 mg/day as monotherapy or as addition to a sulfonylurea, thiazolidinedione or biguanide and were hospitalized

for evaluation by CGM for a 4-day period after 2 months of treatment with either regimen. At hospital discharge, the patients were crossed over to the other regimen, and were hospitalized again after 2 months of treatment for evaluation by CGM for a 4-day period. They were given the same meals on days 2 and 3 during both hospitalizations and were not allowed to take any other additional oral hypoglycemic agent during the study. Variables compared by using the CGM data available from day 2 of either hospitalization with the Wilcoxon signed-rank test included: 1) 24-hour mean glucose levels; 2) standard deviations (SD) of 24-hour; 3) mean amplitude of glycemic excursions (MAGE); 4) preprandial glucose levels; 5) postprandial peak glucose levels; 6) range of glucose increase from preprandial to postprandial peak glucose levels; 7) time from preprandial to postprandial peak glucose levels; and 8) postprandial glucose increase gradients. All statistical analyses were performed by using SPSS ver. 19. The present study was conducted with the approval of the Ethics Committee of Jikei University School of Medicine.

**Results:** The median age of the patients was 59 years (25–75 percentiles, 43–70), their median HbA<sub>1c</sub> (international standards value) 7.1% (6.8–8.1), and their median BMI 26.6 kg/m<sup>2</sup> (25.2–30.3). Their 24-hour mean glucose levels with S and V were significantly ( $P = 0.020$ ) different at 128 and 143 mg/dL, respectively, with their glucose levels being 119 and 130 before breakfast ( $P = 0.035$ ), 108 and 116 before lunch, and 105 and 112 mg/dL before dinner, respectively. The time from preprandial to postprandial peak glucose levels was significantly longer after dinner with V than with S, with that after breakfast, lunch and dinner being 65 and 90, 100 and 140, and 90 and 120 minutes ( $P = 0.013$ ), respectively. The postprandial glucose increase gradient was significantly lower with V after breakfast and dinner, with that after breakfast, lunch and dinner being 1.07 and 0.84 ( $P = 0.047$ ), 0.53 and 0.35, 1.00 and 0.68 ( $P = 0.036$ ) mg/dL/min, respectively. However, no difference was seen between S and V with regard to 24hSD (24.9 and 27.1), MAGE (72.3 and 65.3), postprandial peak glucose levels (morning, 193 and 208; lunch, 157 and 178; and dinner, 188 and 197 mg/dL), and range of postprandial glucose increase (after breakfast, 91 and 80; after lunch, 54 and 42; and after dinner, 87 and 90 mg/dL).

**Conclusion:** A CGM-based study of glycemic variability with S and V revealed that S significantly lowered 24-hour mean glucose levels and glucose levels before breakfast compared to V, while the time from preprandial to postprandial peak glucose levels was significantly longer, and the glucose increase gradient significantly lower after breakfast and dinner, with V compared to S.

**Real life evaluation of DPP4-inhibitors versus other oral antidiabetics in elderly patients with type 2 diabetes mellitus treated with metformin: results from the HYPOCRAS study**

A. Penforis<sup>1</sup>, I. Bourdel-Marchasson<sup>2</sup>, S. Quéré<sup>3</sup>, S. Dejager<sup>3</sup>;

<sup>1</sup>University of Franche-Comté, CHU of Besançon, <sup>2</sup>University Bordeaux, CHU of Bordeaux, <sup>3</sup>Biostatistics & Clinical Research departments, Novartis Pharma SAS, Rueil Malmaison, France.

**Background and aims:** The risk of hypoglycaemia is likely the major complicating factor of antidiabetic treatment in elderly patients and diabetes management is more challenging, although it has received little attention resulting in a paucity of data regarding the use of pharmacological agents in this age group. In this prospective observational study, we evaluated the real life use of DPP4-i vs other oral anti-diabetic drugs (OAD) in elderly patients with T2DM which was not optimally controlled on metformin alone.

**Materials and methods:** Between Sep 2009 and March 2011, 1317 patients  $\geq 65$  years and with HbA<sub>1c</sub>  $\geq 6.5\%$  on metformin were recruited by 663 general practitioners (GP) in France. 2 cohorts were constituted on the basis of the GP decision at the 1<sup>st</sup> visit: to add a DPP4-i or an OAD, and criteria of choice were collected. All patients were followed at 3 (M3) and 6 months (M6) to assess glycaemic control and the rate of reported hypoglycaemic events (HEs). 1188 completed the 6 months follow-up.

**Results:** 78% of patients received a DPP4-i ( $n = 931$ ) vs 22% an OAD ( $n = 257$ ); among these, 63.5% received a SU/glinide, 30% a TZD and 6.6% an  $\alpha$ -glucosidase inhibitor. Demographic characteristics were comparable at baseline (BL) between the 2 cohorts, with 61% of men, mean age of 71 yrs, 7 yrs of disease duration, 5.5 yrs of metformin use and mean BL HbA<sub>1c</sub> of 7.9%. 39% of patients were obese, 13% were smokers, 58% had hypertension, 58% dyslipidemia and about 44% of patients had at least one micro- or macrovascular complication. Despite the lack of difference in the populations

included in the 2 cohorts, GP declared significant differences in the criteria of choice for the second OAD, suggesting that this choice is essentially based on GP's beliefs and experience rather than on actual patients' characteristics. The proportion of patients reporting  $\geq 1$  HE over 6 months was significantly higher in the OOAD cohort: 20.1% vs 6.4% of patients in the DPP4i cohort ( $P < 0.001$ ). While severe HEs were rare in both cohorts, there were significantly more frequent with OOAD (2.4%) vs DPP4-i (0.1%;  $P = 0.001$ ). Further, among patients experiencing  $\geq 1$  HE, patients in the OOAD cohort were more likely to report multiple events with 16% reporting  $\geq 4$  HEs vs 5.5% of the DPP4i patients. Glucose control improved similarly in both cohorts, with HbA<sub>1c</sub> decreasing from a mean BL of 7.9% to 7.1% at M3 (in both cohorts) and to 7.0% (OOAD) and 6.9% (DPP4i) at M6 ( $P = 0.03$ ). However "Success of bitherapy" predefined as reaching the 7% target without any HE at M6, was significantly higher in the DPP4i cohort (59.7%) vs the OOAD cohort (45.5%;  $P < 0.001$ ). Over the course of 6 months, more patients discontinued from the OOAD treatment (6.6%) vs DPP4i (1.6%;  $P < 0.001$ ).

**Conclusion:** The population included in this large cohort study has similar characteristics than the representative sample of the French elderly population described in ENTRED study. While adding a DPP4i or OOAD to elderly patients with T2DM poorly controlled on metformin leads to a similar HbA<sub>1c</sub> decrease at M6, the percentage of patients reaching 7% target without HE is significantly greater with DPP4i. In ENTRED, 5% of patients taking SU or glinides reported  $\geq 1$  severe HE over a 1-year period, which is well consistent with the 2.4% rate seen in HYPOCRAS over 6 months.

## 846

**Contributing factors for initiation of GLP-1 agonist, DPP-4 inhibitor or insulin after metformin or sulfonylurea in US**

S. Schwartz<sup>1</sup>, M. Fournier<sup>2</sup>, H. Wang<sup>3</sup>;

<sup>1</sup>R&D, Main line Health System, Wynnewood, USA, <sup>2</sup>R&D, Sanofi, Paris, France, <sup>3</sup>R&D, Sanofi, Bridgewater, USA.

**Background and aims:** Therapeutic options for Type 2 diabetes after metformin (MET) or sulfonylurea (SU) include GLP-1 agonist (GLP-1), DPP-4 inhibitor (DPP-4) or Insulin. Contributing factors to the choice of therapy are not well understood.

**Materials and methods:** Patient cohorts stable on MET or SU ( $\geq 6$  months) in 2008 and 2009, as baseline (BL), were identified from the IMPACT<sup>TM</sup> claims database and evaluated for the initiation of GLP-1, DPP-4 or insulin in the subsequent year of 2009 and 2010, respectively.

**Results:** Stable MET or SU users were identified in 2008 ( $n=153,582$ ) and 2009 ( $n=148,704$ ). Rate of GLP-1 use was 1.3% to 1.8% and DPP-4 use was 5.4% to 6.1% from 2009 to 2010. Yearly insulin initiation rate remained stable at 3.5%. Mean A1c at BL was 8.1% in those who initiated insulin in 2009 and 8.4% in 2010. Mean A1c at BL was 7.5% for GLP-1 and 7.6% for DPP-4 initiators. At BL, insulin initiators were 85% on MET, 75% on SU and 3 out of 4 on  $\geq 2$  oral agents while GLP-1 and DPP-4 were initiated with 90% BL MET use, less with SU (60%) and two thirds on  $\geq 2$  oral agents. Insulin and DPP-4 initiators had a similar mean age of 57 years, while GLP-1 initiators were about 5 years younger, with more female (51% versus 40% and 43% for DPP-4 and Insulin, respectively) and nearly twice as many medical claims for obesity (21% vs 11% and 13%, respectively). In comparison with DPP-4, insulin initiators had more BL comorbidities, e.g. twice as many renal disease (8% for insulin vs 4% for DPP-4), 30% higher cardiovascular disorders (20% vs 15%) and over 70% more hospital admissions (16% vs 9%). GLP-1 initiators had the least BL comorbidity burden with 3% renal disease, 10% cardiovascular disorder and 8% hospital admissions.

**Conclusion:** Compared to GLP-1 or DPP-4 therapies, insulin is initiated in patients with a high A1c value. GLP-1 is more likely to be initiated in patients with younger age, female gender, lower comorbidity and more obesity.

#### Linagliptin added to sulphonylurea or $\alpha$ -glucosidase inhibitor therapy provides similar long-term safety and efficacy to metformin in Japanese patients with type 2 diabetes

N. Inagaki<sup>1</sup>, H. Watada<sup>2</sup>, M. Murai<sup>3</sup>, T. Kagimura<sup>3</sup>, A. Emser<sup>4</sup>, Y. Gong<sup>4</sup>, S. Patel<sup>5</sup>, H.-J. Woerle<sup>4</sup>;

<sup>1</sup>Department of Diabetes and Clinical Nutrition, Kyoto University Graduate School of Medicine, Kyoto, Japan, <sup>2</sup>Department of Metabolism and Endocrinology, Juntendo University Graduate School of Medicine, Tokyo, Japan, <sup>3</sup>Boehringer Ingelheim, Tokyo, Japan, <sup>4</sup>Boehringer Ingelheim, Ingelheim, Germany, <sup>5</sup>Boehringer Ingelheim, Bracknell, UK.

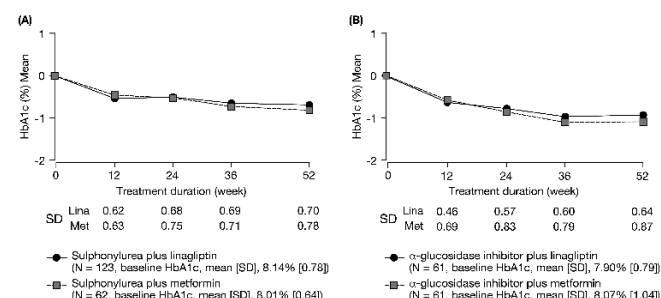

**Background and aims:** To evaluate the long-term safety and efficacy of oral linagliptin 5 mg once daily (Lina) vs metformin (Met), in patients with type 2 diabetes (T2DM) and insufficient glycaemic control despite background monotherapy with an approved oral antidiabetic drug (OAD).

**Materials and methods:** In total, 574 patients with HbA1c  $\geq 7\%$  to  $\leq 10\%$  entered this 52-week, open-label, multicenter, parallel-group trial. After a 2-week placebo run-in, patients on sulphonylurea (SU) or  $\alpha$ -glucosidase inhibitor (A-GI) were randomised to receive either Lina (once daily, 5mg) or Met (twice- or three-times daily, up to 2250 mg/day) as add-on therapy. Additionally, patients on biguanide, glinides, or glitazone received Lina add-on therapy.

**Results:** At week 52, add-on therapy with Lina and Met significantly reduced mean HbA1c levels, from a baseline of 7.9% through 8.1%, in all groups. Add-on therapy with Lina was as effective as Met after 52 weeks: adjusted mean change from baseline HbA1c was  $-0.66\%$  (95% confidence interval, CI,  $-0.81$ ,  $-0.51$ ) for Lina + SU ( $n=123$ ) vs  $-0.84\%$  (CI,  $-1.02$  to  $-0.65$ ) for Met + SU ( $n=62$ ), resulting in a non-significant treatment difference of  $0.18\%$  (CI,  $-0.03$  to  $0.39$ ); corresponding results were  $-0.92\%$  (CI,  $-1.10$  to  $-0.73$ ) for Lina + A-GI ( $n=61$ ) vs  $-1.00\%$  (CI,  $-1.17$  to  $-0.83$ ) for Met + A-GI ( $n=61$ ), resulting in a non-significant treatment difference of  $0.09\%$  (CI,  $-0.13$  to  $0.30$ ). Descriptive statistics demonstrate the consistent and sustained HbA1c decline over the 52-week treatment period (Figure). Adverse events (AE) were mostly mild or moderate and the rates were comparable across all groups: in SU-treated patients, AEs were reported in 82% of the Lina group and 70% of Met group, whilst in A-GI-treated patients, rates were 80% and 85%, respectively. The occurrence of hypoglycaemic events was similar for Lina and Met, and all were mild in intensity, except one event in the SU + Met group (moderate). In the A-GI group, hypoglycaemic events were reported in 2% (1/61) in the Lina add-on group, and 3% (2/61) receiving Met add-on. For those on SU background, corresponding rates were increased to 14% (17/124) of patients receiving add-on Lina vs 16% (10/63) receiving add-on Met.

**Conclusion:** Once-daily linagliptin provides well-tolerated, effective add-on therapy leading to significant HbA1c reductions, similar to metformin, over 52 weeks in Japanese patients with inadequately controlled T2DM despite monotherapy with an approved OAD.

Change from baseline HbA1c over time in patients receiving background therapy with sulphonylurea (A) or  $\alpha$ -glucosidase inhibitor (B) plus add-on linagliptin or metformin

Clinical Trial Registration Number: NCT01204294

Supported by: Boehringer Ingelheim

### 848

#### Safety and efficacy of linagliptin plus basal insulin combination therapy in a vulnerable population of elderly patients (age $\geq 70$ years) with type 2 diabetes

H.-J. Woerle<sup>1</sup>, D. Neubacher<sup>2</sup>, S. Patel<sup>3</sup>, M. von Eynatten<sup>1</sup>;

<sup>1</sup>Boehringer Ingelheim, Ingelheim, Germany, <sup>2</sup>Boehringer Ingelheim, Biberach, Germany, <sup>3</sup>Boehringer Ingelheim, Bracknell, UK.

**Background and aims:** Elderly patients with type 2 diabetes (T2D) are commonly characterised by longer disease duration and diminished  $\beta$ -cell capacity, which often requires combination therapy with basal insulin. Increasing the insulin dose is one option to improve glycaemic control, but this often presents a higher risk of hypoglycaemia, which increases overall safety concerns in this vulnerable population. Elderly patients may therefore benefit from an alternative option, such as an additional oral antidiabetic drug that can be administered safely in combination with their background basal insulin. Linagliptin is a recently approved oral DPP-4 inhibitor that has shown clinically meaningful efficacy and an overall safety profile similar to placebo in commonly used oral antidiabetic treatment regimens. It also has a once-daily, single-dose strength posology without the need for dose adjustment in patients with hepatic and/or renal impairment, which allows for convenient dosing and may support patient adherence.

**Materials and methods:** Two Phase 3 studies evaluating linagliptin vs. placebo as add-on therapy to basal insulin and as T2D management in elderly patients were eligible for a pre-specified pooled analysis exploring its safety and efficacy in combination with basal insulin in elderly patients (age  $\geq 70$  years) with T2D. The primary efficacy endpoint was change from baseline to week 24 in HbA1c. Safety and tolerability based on adverse events (AEs) were also assessed.

**Results:** A total of 247 patients inadequately controlled on insulin glargine, insulin detemir, or NPH insulin received either linagliptin 5 mg once daily ( $n=126$ ) or placebo ( $n=121$ ). Mean insulin doses were 35.0 IU and 36.6 IU, respectively. Baseline age and HbA1c were 74.3 years and 8.2% in both groups. Overall, 95.1% of all individuals had a diabetes duration  $>5$  years. At week 24, the placebo-adjusted mean change in HbA1c with linagliptin was  $-0.77\%$  (95% CI:  $-0.95$ ,  $-0.59$ ;  $P < 0.0001$ ). AE rates were generally lower with linagliptin than placebo. The overall incidence of AEs was 75.4% with linagliptin and 81.0% with placebo. Drug-related AE rates were 16.7% with linagliptin and 20.7% with placebo. The majority of AEs with either linagliptin or placebo were mild-to-moderate in intensity (severe AE rates: 5.6% vs. 7.4%, respectively) and most were non-serious in nature (serious AE rates: 9.5% vs. 18.2%, respectively). Hypoglycaemia occurred in 28.6% on linagliptin and 37.2% on placebo. The frequency of premature discontinuation was lower with linagliptin than with placebo (7.1% vs. 14.0%, respectively). The most common reasons for occurrence of an AE (4.0% on linagliptin vs. 3.3% on placebo) and refusal to continue trial medication (1.6% on linagliptin vs. 5.0% on placebo).

**Conclusion:** In this vulnerable elderly population, linagliptin in combination with basal insulin was well tolerated and achieved clinically meaningful improvements in glycaemic control without excessive risk of hypoglycaemia.

Clinical Trial Registration Number: NCT00954447 & NCT01084005

### 849

#### Efficacy and safety of linagliptin as add-on therapy to sulphonylurea (SU) in type 2 diabetes patients with moderate or severe renal impairment (RI)

M. von Eynatten<sup>1</sup>, A.H. Barnett<sup>2</sup>, S. Patel<sup>3</sup>, D. Neubacher<sup>4</sup>, H.-J. Woerle<sup>1</sup>;

<sup>1</sup>Boehringer Ingelheim, Ingelheim, Germany, <sup>2</sup>University of Birmingham and Heart of England NHS Foundation Trust, Birmingham, UK, <sup>3</sup>Boehringer Ingelheim, Bracknell, UK, <sup>4</sup>Boehringer Ingelheim, Biberach, Germany.

**Background and aims:** Since metformin is not recommended in patients with type 2 diabetes mellitus (T2DM) and more advanced forms of RI, combination therapy with a DPP-4 inhibitor and a SU may be a viable alternative. In contrast to other DPP-4 inhibitors, linagliptin has a primarily non-renal route of excretion and a one-strength, once-daily dose. We evaluated the efficacy and safety of linagliptin as add-on to SU in T2DM patients with moderate or severe RI based on estimated GFR.

**Materials and methods:** A post-hoc analysis was conducted that included data from three Phase 3, randomised, double-blind, placebo-controlled studies of linagliptin 5 mg once daily for treatment of T2DM. Only patients in which linagliptin was added to background SU were eligible for the analysis.

Study 1 was conducted over 24 weeks in elderly patients ( $\geq 70$  years;  $\pm$  insulin  $\pm$  oral antidiabetes background therapy), Study 2 over 18 weeks in patients with insufficient glycaemic control on SU monotherapy, and Study 3 over 12 weeks (primary efficacy endpoint; full study was 52 weeks) in patients with severe chronic RI ( $\pm$  insulin  $\pm$  oral antidiabetes background therapy).

**Results:** Across the studies, 91 patients were identified with moderate or severe RI who had previously received SU; of these 58 received linagliptin and 33 received placebo. Baseline values for linagliptin versus placebo were: age (SD), 69 (10.2) vs 70 (8.3) years; male sex, 67% vs 55%; and HbA1c (SD), 8.2% (1.1) vs 8.1% (0.6). Overall, 91.2% of patients had diabetes duration  $> 5$  years and 62.6% were receiving  $\geq 2$  antidiabetes drugs at enrolment. Significantly greater ( $P < 0.05$ ) decreases in HbA1c compared with placebo (adjusted mean [SE]) were observed in Study 1 ( $-0.68\%$  [0.25]) and 2 ( $-1.08\%$  [0.43]), and a trend for a numerically greater decrease in Study 3 ( $-0.62\%$  [0.31];  $P = 0.06$ ) (Table). Across all studies, adverse events (AEs) and serious AEs were similar between linagliptin and placebo: 46 (79.3%) and 13 (22.4%) compared with 25 (75.8%) and 9 (27.3%), respectively. The overall incidence of hypoglycaemia was slightly lower in patients on linagliptin (22/58; 37.9%) compared with placebo (13/33; 39.4%). Hypoglycaemic events with linagliptin were mostly of mild intensity; 12 patients (20.7%) experienced a mild episode while only 1 patient (1.7%) experienced a severe episode. There was no difference between the two groups with regards to changes in body weight in any of the studies.

**Conclusion:** In patients with moderate or severe RI, linagliptin as an add-on treatment to SU resulted in clinically important reductions in HbA1c without an unacceptable risk of AEs. In particular, the incidence of hypoglycaemia was not further increased with linagliptin. Our data support the use of linagliptin as add-on to SU in this difficult to treat population in which treatment alternatives are scarce.

Table							
Study (duration)	Treatment	N	Baseline mean (SD)	Adjusted mean change from baseline (SE)	Difference to placebo		
					Adjusted mean (SE)	95% CI	P-value
HbA1c, %							
1 (24 weeks)	Placebo	10	7.77 (0.60)	-0.05 (0.23)	-0.68 (0.25)	-1.19, -0.17	0.01
	Linagliptin	26	7.96 (0.76)	-0.73 (0.14)			
2 (18 weeks)	Placebo	8	8.34 (0.57)	0.29 (0.31)	-1.08 (0.43)	-2.02, -0.14	0.03
	Linagliptin	9	8.62 (0.48)	-0.79 (0.29)			
3 (12 weeks)	Placebo	15	8.15 (0.56)	-0.25 (0.24)	-0.62 (0.31)	-1.25, 0.01	0.06

### Safety and efficacy of linagliptin in elderly patients with type 2 diabetes: evidence from 1331 individuals aged $\geq 65$ years

S. Patel<sup>1</sup>, G. Scherthaner<sup>2</sup>, A.H. Barnett<sup>3</sup>, A. Emser<sup>4</sup>, M. von Eynatten<sup>4</sup>, H.-J. Woerle<sup>4</sup>;

<sup>1</sup>Boehringer Ingelheim Ltd, Bracknell, UK, <sup>2</sup>Department of Medicine I Rudolfstiftung Hospital, Vienna, Austria, <sup>3</sup>University of Birmingham and Heart of England NHS Foundation Trust, Birmingham, UK, <sup>4</sup>Boehringer Ingelheim, Ingelheim, Germany.

**Background and aims:** The treatment of type 2 diabetes mellitus (T2DM) in elderly patients can be challenging because of safety and tolerability concerns, such as associated co-morbidities and higher risk of treatment-related complications, including hypoglycaemia and gastrointestinal (GI) side-effects. Using pooled data from the large, international linagliptin Phase 3 program, we investigated the safety and efficacy of linagliptin in elderly patients.

**Materials and methods:** Data ( $n = 1331$ ) were pooled from 7 randomised, double-blind, placebo-controlled Phase 3 trials of linagliptin 5 mg once daily as monotherapy or add-on to various glucose-lowering therapies of at least 24 weeks duration. This post-hoc sub-analysis comprised all patients aged  $\geq 65$  years. Safety and efficacy parameters for this analysis were assessed up to week 24.

**Results:** In total, 841 patients received linagliptin and 490 received placebo. Mean (SD) baseline characteristics were similar in the linagliptin vs placebo

groups: age, 71.1 (4.5) vs 70.9 (4.7) years; BMI, 29.5 (5.0) vs 30.0 (4.9) kg/m<sup>2</sup>; HbA1c, 8.0% (0.8) vs 8.1% (0.8). Overall, 21% of patients had renal function decline (eGFR  $< 60$  mL/min), more than 80% of patients had diabetes duration  $> 5$  years and more than 60% of patients were receiving  $\geq 2$  glucose-lowering drugs. Median exposure to linagliptin and placebo was 173.0 and 176.5 days, respectively. The placebo-adjusted mean (95% CI) change in HbA1c from baseline to week 24 was  $-0.62\%$  ( $-0.73, -0.51$ ;  $P < 0.0001$ ) for patients who received linagliptin (Figure). A significantly greater reduction in fasting plasma glucose (FPG) from baseline to week 24 was noted for linagliptin (placebo-adjusted mean [95% CI] change:  $-14.8$  mg/dL [ $-20.7, -8.9$ ];  $P < 0.0001$ ;  $-0.82$  mmol/L [ $-1.15, -0.49$ ]). Adverse events (AEs) were experienced by 71.3% and 73.3% of patients who received linagliptin and placebo, respectively, and drug-related AEs were less frequent with linagliptin treatment (18.1%) than with placebo (19.8%). The incidence of hypoglycaemia was slightly lower in patients who received linagliptin (21.4%) compared with placebo (25.7%). Severe hypoglycaemic events requiring assistance were rare in both groups (1.0% and 1.8%, respectively). Overall AE reporting for GI disorders was comparable between both groups (14.1% and 15.5%, respectively). At least one adjudicated cardiovascular event was experienced by 0.8% and 1.0% of linagliptin- and placebo-treated patients, respectively.

**Conclusion:** Although this patient population is frequently compromised in renal function and is at high risk for hypoglycaemia, linagliptin is well tolerated and an efficacious treatment option in elderly patients without the need for dose adjustment.

**Figure:** Mean change in HbA1c over time. Full analysis set (LOCF analysis)

<sup>1</sup>Korea University Guro Hospital, Republic of Korea, <sup>2</sup>Eulji Medical Center Medical Corporation, Seoul, Republic of Korea, <sup>3</sup>Asan Medical Center, Asan Public Welfare Foundation, Seoul, Republic of Korea, <sup>4</sup>Kangdong Sacred Heart Hospital, Seoul, Republic of Korea, <sup>5</sup>Inha University Hospital, Incheon, Republic of Korea, <sup>6</sup>MV Hospital and Research Centre, Lucknow, India, <sup>7</sup>RHIDEM, Mumbai, India, <sup>8</sup>Pitale Diabetes and Hormone Center, Nagpur, India, <sup>9</sup>Hormone care and research centre, Ghaziabad, India, <sup>10</sup>Diacon Hospital, Diabetes Care and Research Centre, Bangalore, India, <sup>11</sup>Bangalore Endocrinology and Diabetes Research Centre, Bangalore, India, <sup>12</sup>Gandhi Research Institute, Nagpur, India, <sup>13</sup>Madras Diabetes Research Foundation, Chennai, India, <sup>14</sup>LG Life Sciences, Seoul, Republic of Korea.

**Background and aims:** This study was designed to assess the efficacy and safety of a DPP IV inhibitor, gemigliptin (LC15-0444) 50mg versus placebo in patients with type 2 diabetes.

**Materials and methods:** We conducted a 24-week, randomized, double-blind, placebo-controlled phase III trial in 182 patients (74 from Korea and 108 from India) with type 2 diabetes. After initial 2 weeks of exercise/diet program followed by another 2 weeks of single-blind placebo run-in period, eligible patients were randomized to gemigliptin 50mg or placebo group and received the assigned treatment for 24 weeks. HbA1c and fasting plasma glucose (FPG) were measured periodically, and oral glucose tolerance tests were performed at baseline, week 12 and week 24.

**Results:** At week 24, gemigliptin treatment led to significant reductions in HbA<sub>1c</sub> compared with placebo in HbA<sub>1c</sub> (-0.71%). A significantly greater proportion of patients achieved an HbA<sub>1c</sub> <7% with gemigliptin than with placebo. The placebo-subtracted FPG change from baseline at week 24 was -19.80 mg/dL. The overall incidence rate of adverse events in the gemigliptin and in the placebo was similar between the two groups.

**Conclusion:** In conclusion, this study demonstrated the efficacy and safety of gemigliptin 50mg administered once daily as a monotherapy in type 2 diabetes patients.

<sup>1</sup>Kangbuk Samsung Medical Center, Seoul, Republic of Korea, <sup>2</sup>Eulji Medical Center Medical Corporation, Seoul, Republic of Korea, <sup>3</sup>Seoul National University Bundang Hospital, Gyeonggi, Republic of Korea, <sup>4</sup>Wonju Christian Hospital, Gangwon, Republic of Korea, <sup>5</sup>Ulsan University Hospital, Ulsan, Republic of Korea, <sup>6</sup>Chosun University Hospital, Gwangju, Republic of Korea, <sup>7</sup>Samsung Medical Center, Seoul, Republic of Korea, <sup>8</sup>Korea University Guro Hospital, Seoul, Republic of Korea, <sup>9</sup>RHIDEM, Mumbai, India, <sup>10</sup>Diacon Hospital, Diabetes Care and Research Centre, Bangalore, India, <sup>11</sup>Bangalore Endocrinology and Diabetes Research Centre, Bangalore, India, <sup>12</sup>Gandhi Research Institute, Nagpur, India, <sup>13</sup>M V Hospital and Research Centre, Lucknow, India, <sup>14</sup>LG Life Sciences, Seoul, Republic of Korea

**Background and aims:** This study was designed to assess the efficacy and safety of a DPP IV inhibitor, gemigliptin (LC15-0444) 50mg versus sitagliptin 100mg in patients with type 2 diabetes continuing metformin treatment.

**Materials and methods:** We conducted a 24-week, double-blind, randomized, active-controlled trial in 425 patients (296 from Korea, 129 from India) with type 2 diabetes inadequately controlled with metformin alone. Eligible patients were randomized to one of 3 treatment groups and gemigliptin 50mg qd or gemigliptin 25mg bid or sitagliptin 100mg qd was added to ongoing metformin treatment for 24 weeks. HbA<sub>1c</sub> and fasting plasma glucose (FPG) were measured periodically, and oral glucose tolerance tests were performed at baseline, and week 24.

**Results:** At week 24, gemigliptin 50mg/day added to ongoing metformin therapy resulted significant improvement of glycemic control supported by the followings. Reduction in HbA<sub>1c</sub> of gemigliptin 50mg qd (-0.77%) was non-inferior to those once daily sitagliptin 100mg (-0.83%). Proportion of patients achieving HbA<sub>1c</sub> <7% or 6.5% in gemigliptin 25mg bid (50%) and gemigliptin 50mg qd (54.07%) was comparable to the results with once daily sitagliptin 100 mg (48.87%). There was decrease in FPG, postprandial glucose, AUC<sub>0-2h</sub> glucose, DPP 4 activity and increase in GLP-1, sensitivity of beta cells to glucose (supported by HOMA-β, HOMA-IR, postprandial (2h) c-peptide, insulinogenic index, and postprandial proinsulin to insulin ratio) in patients who were administered with gemigliptin 50mg/day added to ongoing metformin therapy. There was no increased risk of adverse experience with gemigliptin 50mg/day compared with sitagliptin 100mg qd.

**Conclusion:** In conclusion, gemigliptin 50mg/day as an add-on therapy to metformin was efficacious and well tolerated in type 2 diabetes mellitus patients.

### DPP-4 inhibitor vildagliptin reduces postprandial RLP-cholesterol and RLP-triglycerides in type 2 diabetes

N. Matikainen, M.-R. Taskinen;

Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland.

**Background and aims:** Pharmacological inhibition of DPP-4 has been shown to reduce triglyceride (TG)-rich lipoproteins in experimental studies, suggesting that DPP-4 inhibitors may improve postprandial diabetic dyslipidemia. If Vildagliptin (VILDA) reduces postprandial atherogenic remnant

particles is unknown. Therefore, we assessed the effects of VILDA on remnant like-particle cholesterol (RLP-Chol), RLP-TG, apolipoprotein (apo) A5, and apoCIII concentrations in a randomized clinical trial in subjects with T2DM.

**Materials and methods:** Current data represent a substudy of our previous study with twenty-three drug-naïve T2DM patients (age 39-69 years), who participated in this single-centre, randomized, double-blind, placebo-controlled, parallel-group study of 4-week duration. Entry criteria included HbA<sub>1c</sub> of 6.5-10.0%, fasting plasma glucose of <13.3 mmol/L, fasting TG of 1.7-5.0 mmol/L and BMI of 25-40 kg/m<sup>2</sup>. Subjects with an apo E2-allele or lipid-lowering therapy within 3 months prior to screening were excluded from the study. We measured RLP-cholesterol, RLP-TG, apoA5 and apoCIII before and 3, 4, 6 and 8 hrs after an oral fat load (72 g fat, 50 g carbohydrates, 35 g protein) at week 0 and 4 during VILDA 50 mg bid.

**Results:** At baseline, subjects receiving VILDA (n=11) and PBO (n=12) had comparable age, BMI, glycemic control and fasting TG. Treatment with VILDA produced significant reduction by -35.4 mg/dL\*h (p=0.035), in postprandial RLP-cholesterol area under the curve (AUC) from week 0 to 4, while no change occurred with PBO (RLP-cholesterol AUC change +5.2 mg/dL\*h, NS). Plasma TG AUC decreased in VILDA group, but not in PBO group. In accordance, RLP-TG AUC decreased by -339 mg/dL\*h with VILDA (p=0.011) from week 0 to 4 but remained unchanged with PBO (+121 mg/dL\*h, NS). Furthermore, treatment with VILDA produced borderline-significant reduction in postprandial apoA5 AUC from week 0 to 4 (p=0.082 for VILDA, NS for PBO). We detected no changes in postprandial apoCIII AUC in either group. HbA<sub>1c</sub> at baseline averaged 6.9±0.7% and 6.8±0.7% in patients treated with VILDA and PBO, respectively. In patients randomized to VILDA HbA<sub>1c</sub> decreased by 0.5% from week 0 to 4 (p<0.01), while it remained unchanged in PBO group. **Conclusion:** Treatment with VILDA reduces postprandial RLP-cholesterol and RLP-TG i.e. atherogenic RLP remnant particles. These changes may contribute to an improved cardiovascular risk profile in patients with T2DM.

### Persistence of treatment with DPP-4 inhibitors and sulfonylureas in primary care practices in Germany and France: a retrospective analysis

J. Rex<sup>1</sup>, K. Kostev<sup>1</sup>, J.-B. Gruenberger<sup>2</sup>, G. Bader<sup>2</sup>, M. Dworak<sup>3</sup>, W. Rathmann<sup>4</sup>, G. Giani<sup>4</sup>;

<sup>1</sup>TMS Health, Epidemiology, Frankfurt, <sup>2</sup>Novartis Pharma AG, Basel, Switzerland, <sup>3</sup>Novartis Pharma GmbH, Nuernberg, <sup>4</sup>Institute of Biometrics and Epidemiology, Düsseldorf, Germany.

**Background and aims:** Persistence with medications is essential for therapeutic success in chronic diseases such as type 2 diabetes mellitus (T2DM). The persistence, i.e. the extent to which patients continue treatments and regularly take their medications, was compared for dipeptidyl peptidase-4 inhibitors (DPP-4s) and sulfonylureas (SUs) in primary care practices in Germany and France.

**Materials and methods:** Non-persistence was defined as a period of ≥90 days without prescriptions (DPP-4s, SUs). Longer intervals were considered as treatment gaps and the anti-diabetic therapy of patients was classified as no longer persistent (maximum follow-up duration: 2 years). New prescriptions (index date) of DPP-4 and SU (ATC codes) in patients with T2DM without additional anti-diabetic agents except for metformin in primary care practices in Germany (n=1,201 physicians) and in France (n=682 physicians) were retrospectively analysed (Disease Analyser database, 04/2007-08/2011). The lack of persistence (DPP-4s vs. SUs) was compared using Cox regression models after adjusting for age, sex, diabetes duration, episodes of hypoglycaemia, health insurance (private), practice region, and Charlson Comorbidity Index.

**Results:** After two years, 61% of patients treated with DPP-4s (n=17,312) and only 51% of patients treated with SUs (n=30,382) in German practices persisted with their anti-diabetic treatment. Similar results were found in France where 59% of patients treated with DPP-4s (n=8,675) vs. 51% with SUs (n=11,150) persisted with their treatments. In the adjusted Cox model, prescriptions of DPP-4s compared to SUs were associated with a lower risk of discontinuation of therapy in Germany (hazard ratio: 0.74 [95% CI: 0.71, 0.76]; p<0.001). A similarly reduced risk of discontinuation was found in patients in France (HR: 0.79 [95% CI: 0.75, 0.83]; p<0.001).

**Conclusion:** Lack of persistence with anti-diabetic therapy is a common problem in patients with T2DM treated in primary care practices in Germany and France. A larger proportion of patients on DPP-4 inhibitors persisted with

treatment compared to sulfonylureas. The potential reasons for this difference including hypoglycaemia and weight gain must be investigated in further studies.

### Clinical outcome of treatment with DPP-4-inhibitors or GLP-1-analogues in patients with type 2 diabetes treated in diabetes specialised medical practices in Germany

G. Hess, winDiab;  
winDiab, Düsseldorf, Germany.

**Background and aims:** In many patients with Type 2 diabetes treated in daily life in Diabetes Specialized Medical Practices (DSP) a treatment with a DPP-4-inhibitor (DPP-4) or GLP-1-analog (GLP-1) is started. We analysed the outcome of this treatment in 907 patients treated in 38 DSPs for a maximal period of 1 year with respect to factors that have an impact on the success of incretin-based treatment in an observational study.

**Materials and methods:** After the decision for an incretin based therapy was made in a mutual conclusion between the patient and the diabetologist they were included in this study independent of their pre-treatment. A number of parameters was documented at start of therapy and was evaluated again after 3, 6 and 12 months (also if treatment with an incretin-based drug was stopped before). The patients were analysed according to the incretin drug they were treated with: DPP-4: 437 patients, female 44.4%, age 59±12 years, duration of diabetes 8.4±6.7 years, HbA1c 8.4±1.5%, BMI 34.2±6.9 kg/m<sup>2</sup>; GLP-1: 470 patients, female 50.2%, 56±10 years, 9.1±5.8 years, 8.4±1.4%, 39.3±7.2 kg/m<sup>2</sup>. These groups were further subdivided in the analysis according to pre-established insulin therapy.

**Results:** In both groups one drug was used most often: DPP-4: Sitagliptin n= 327 patients (75%; related to the 437 patients/100% in this group), Vildagliptin 76 (17%), Saxagliptin 34 (8%); GLP-1: Liraglutid 402 (86%; related to the 470 patients in this group), Exenatide 68 (14%). From those treated with DPP-4 223 patients (51%) were still treated with such a drug after 12 months, from those treated with GLP-1 262 (56%). In the other patients treatment was stopped (105, 24% vs. 142, 30%) or they did not come back to the follow-up visits (109, 24% vs. 66, 14%). Main reasons for stopping treatment were: Insufficient effect (60, 57% of 105 vs. 115, 81% of 109), side effects (24, 23% vs. 28; 20%) or patient's wish (27, 26% vs. 18, 13%). Treatment with a DPP-4 for 12 months induced a reduction in BMI by 0.4 kg/m<sup>2</sup> (median difference; from 32.8 to 32.2 kg/m<sup>2</sup> (median)); with GLP-1 the decline was 1.5 kg/m<sup>2</sup> (from 39.1 to 37.2 kg/m<sup>2</sup>; p<0.001). HbA1c was lowered by 0.6% (from 7.8% to 7.2%) by DPP-4 and by 0.1% (from 8.2% to 7.8%) in patients treated with GLP-1 that were previously treated with insulin and by 1.1% (from 8.3% to 7.1%; p<0.001) in those without previous insulin. A reduction in HbA1c by more than 1.0% was observed in 61 (37%) of 164 patients treated with DPP-4 without insulin at start of therapy and in 17 (29%) of 59 with insulin. In the patients treated with GLP-1 such a reduction was observed in 70 (51%) of 137 patients without insulin at start, but in only 28 (22%) of the 125 with insulin.

**Conclusion:** In a considerable number of patients treated with either of these new drugs the treatment ended within 12 months despite being treated in a DSP. GLP-1 induced a more pronounced improvement in metabolic control (depending on the therapy before) and also lowering of body weight as DPP-4 (starting at different levels). However, in individual patients a considerable improvement in both parameters (metabolic control and body weight) was observed without having clear predictive parameters for treatment success.

## PS 068 DPP-4 inhibitors II

### 856

#### Vildagliptin efficacy and safety in patients with type 2 diabetes inadequately controlled on dual metformin plus sulfonylurea therapy

V. Lukashevich<sup>1</sup>, M. Wang<sup>1</sup>, S. Del Prato<sup>2</sup>, M. Araga<sup>3</sup>, W. Kothny<sup>1</sup>;

<sup>1</sup>Novartis Pharmaceutical Corporation, East Hanover, USA, <sup>2</sup>University of Pisa, Italy, <sup>3</sup>Novartis Pharma AG, Basel, Switzerland.

**Background and aims:** The combination of metformin (MET) plus a sulfonylurea (SU) is broadly used for the treatment of type 2 diabetes (T2DM). However, many patients on dual therapy still do not achieve glycaemic control. Adding a third oral agent can be an option for patients before initiating insulin therapy. Vildagliptin (VILDA), a potent and selective dipeptidyl peptidase-4 inhibitor with proven efficacy with either MET or an SU, was assessed in such a triple therapy setting.

**Materials and methods:** The efficacy and safety of VILDA 50 mg bid as add-on therapy to a stable dose of MET (≥ 1500 mg) plus glimepiride (≥ 4 mg) was assessed in a multi-center, double-blind, randomised, placebo-controlled 24-week study in 318 T2DM patients (N=158 on VILDA and N= 160 on placebo) with inadequate glycaemic control (HbA1c ≥7.5 and ≤11%). The HbA1c change versus placebo was the primary study endpoint.

**Results:** The study population had a mean age of 55.1 years, mean T2DM duration of 7.3 years, mean BMI of 28.0 kg/m<sup>2</sup>, mean fasting plasma glucose (FPG) of 9.4 mmol/L and mean HbA1c of 8.8%. VILDA demonstrated a clinically relevant and statistically significant reduction in HbA1c compared to placebo (Table 1). Approximately 30% of VILDA-treated patients reached HbA1c target <7% vs. 6% in the placebo group (p<0.001). The difference in FPG reduction between VILDA and placebo of 1.13 mmol/L (baseline FPG 9.34 mmol/L and 9.52 mmol/L, respectively) was also clinically and statistically significant (p<0.001). VILDA was well tolerated with an overall safety profile similar to placebo. The rate of hypoglycaemia was overall low but slightly higher with VILDA than with placebo (5.1% vs. 1.9%). There was no clinically relevant weight gain with VILDA.

**Conclusion:** VILDA 50 mg bid demonstrated robust glucose-lowering efficacy in patients with T2DM inadequately controlled on dual metformin plus glimepiride therapy. The triple combination with VILDA was safe and well tolerated with low risk of hypoglycaemia and weight gain. This makes vildagliptin an attractive treatment addition for patients failing on dual metformin and SU therapy.

# Vildagliptin added to once or twice daily insulin regimens improves glycaemic control without increasing risk of hypoglycaemia and weight gain in patients with type 2 diabetes

W. Kothny<sup>1</sup>, P. Kozlovski<sup>2</sup>, J. Foley<sup>1</sup>, Q. Shao<sup>1</sup>, V. Lukashevich<sup>1</sup>

<sup>1</sup>Novartis Pharmaceutical Corporation, East Hanover, USA, <sup>2</sup>Novartis Pharma AG, Basel, Switzerland.

**Background and aims:** Vildagliptin (Vilda) blocks dipeptidyl peptidase-4 (DPP-4) inhibition of glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) which extends their physiological effects, thereby increasing islet alpha- and beta-cell responsiveness to glucose. While both GLP-1 and GIP enhance glucose mediated insulin (INS) secretion GLP-1 reduces glucagon levels in hyperglycaemia and GIP increases glucagon in hypoglycaemia. We previously reported that Vilda 50 mg bid added to INS monotherapy in patients with type 2 diabetes mellitus (T2DM) provided 0.3% reduction in HbA1c vs. placebo (Pbo) with reduced risk of hypoglycaemia. The efficacy results were confounded by a high dose INS (>80 U/day) regimen with significant short acting INS usage suppressing endogenous insulin secretion. We now report a 24-week study to assess the efficacy and safety of Vilda in patients with T2DM inadequately controlled by stable basal, intermediate acting, or pre-mixed INS, with or without concomitant metformin, which is considered to be more reflective of current practice than the previous trial.

**Materials and methods:** In a 24-week, multicentre, randomised, double-blind, parallel-group, placebo controlled study 449 patients with T2DM on stable insulin therapy with long-acting, intermediate-acting or pre-mixed insulin were randomized to vildagliptin 50 mg bid (N=228) and placebo (N=221). Stable metformin background therapy was permitted. The primary endpoint was efficacy expressed as change in HbA1c versus placebo. Safety and tolerability were also evaluated.

**Results:** Patients in this trial were 59 years old with a T2DM duration of 13 years. 60.6% of patients were on premixed INS regimens, 23% on long-acting and 16.4% on intermediate acting INS. The mean dose of INS was 40.9 U/day and approximately 60% of patients were on stable metformin background therapy. Vilda significantly reduced HbA1c compared to Pbo in the overall population and sub-groups with or without metformin (Table 1). Overall Vilda was safe and well tolerated with no weight increase. Incidences of hypoglycaemia (8.4% vs 7.2%) and severe hypoglycaemia events (0.9% in both groups) were similarly low in Vilda and Pbo patients respectively despite the substantially greater HbA1c reduction with Vilda.

**Conclusion:** Usually increased hypoglycaemia limits the efficacy of oral hypoglycaemic agents in combination with INS. Vilda not only significantly lowered HbA1c without weight gain, but also did not increase hypoglycaemia incidence presumably due to a GIP mediated counter-regulatory glucagon effect. Thus, Vilda is an attractive combination partner with INS, with or without concomitant metformin therapy.

# Vildagliptin as add-on therapy to other oral antidiabetics in Japanese patients with type 2 diabetes

M. Suzuki<sup>1</sup>, I. Hamada<sup>2</sup>, M. Odawara<sup>3</sup>, LAF237A1308 Study Group;

<sup>1</sup>Primary Care Clinical Franchise Dept., Novartis Pharma KK, <sup>2</sup>IHC/RESP IIS Franchise Dept., Novartis Pharma KK, <sup>3</sup>The Third Department of Internal Medicine, Tokyo Medical University, Japan.

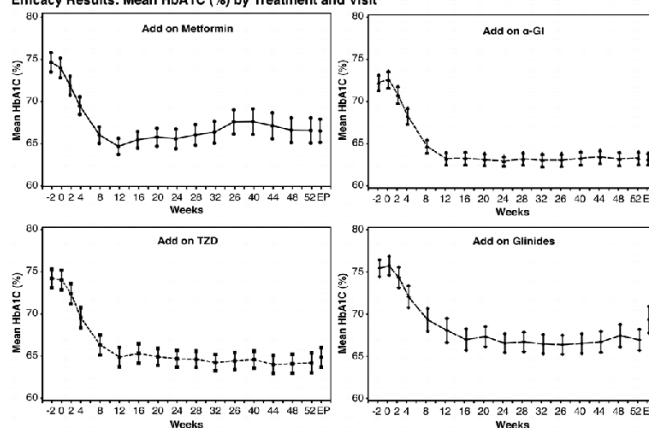

**Background and aims:** We report efficacy results from a long-term (52-week) safety and tolerability study in Japanese patients with vildagliptin as add-on therapy to approved oral antidiabetic drugs (OADs) including metformin, thiazolidinediones (TZD), alpha-glucosidase inhibitors (α-GI), or glinides. Efficacy variables included change from baseline to endpoint (week 52 or final study visit) in HbA1c and fasting plasma glucose (FPG), while safety analyses compared the incidence of adverse events (AEs) during the treatment period.

**Materials and methods:** Two hundred and forty five eligible patients (vildagliptin + metformin, n=58; vildagliptin + TZD, n=62; vildagliptin + α-GI, n=62; vildagliptin + glinide, n=63), uncontrolled on monotherapy, were included in this 52-week, multicentre, open-label study. All enrolled patients were included in the Safety and Full Analysis Set populations.

**Results:** Treatment groups were well-balanced for baseline demographic and background characteristics. Mean age of patients was 59.5 years (~65% were <65 years old). Mean baseline values of HbA1c (JDS unit), FPG and BMI were 7.41%, 161.3 mg/dL and 25.6 kg/m<sup>2</sup> respectively. Mean duration of diabetes was 6.5 years. Of the enrolled patients, 86.1% completed the study. Mean change in HbA1c was -0.81% (95% CI -0.91, -0.71). Overall, 62.2% patients achieved HbA1c <7.0% and 71.4% had HbA1c improved by ≥0.5% at endpoint. The figure shows change in mean HbA1c in each group over time. HbA1c change was lowest in the glinide group (-0.64% [95% CI -0.85, -0.43]) and highest in the α-GI group (-0.94% [95% CI -1.15, -0.74]). Furthermore, the glinide group had lower HOMA-B (25.663) and C-peptide (1.38 ng/mL), and higher HOMA-IR levels (3.259) at baseline than other groups. The percentage of patients reporting an AE (≥3%) was comparable in all groups; 86.5% experienced at least one AE. Infections (50.6%) were the most frequently occurring pre-defined risk, of which nasopharyngitis (30.6%) was most frequently reported. All cases of infections were mild or moderate. Overall 19 serious AEs occurred in 15 patients (6.1%). No deaths were reported. Percentage of patients discontinuing from the study was more in the glinide group (23.8%) than other groups (6.5%-16.1%). One patient experienced mild hypoglycaemia in the metformin add-on group.

**Conclusion:** Vildagliptin (50 mg bid) was generally safe, well tolerated, and resulted in clinically significant reduction in HbA1c across treatment groups, when used as add-on therapy to other OADs in patients with T2DM, in a first of its kind study in Japan.

Efficacy Results: Mean HbA1C (%) by Treatment and Visit

Unadjusted means and standard errors (vertical bars) are given. Baseline measurement is obtained on Day 0 or sample obtained on an earlier visit (scheduled/unscheduled) closest to Day 0, if Day 0 measurement is missing. EP (Endpoint) is the final available post-baseline assessment up to the last regular scheduled visit. HbA1c is reported in JDS unit (%). HbA1c (NGSP, %) = HbA1c (JDS, %) + 0.4.

Clinical Trial Registration Number: NCT01159249

## 859

**Vildagliptin improves a chronic effect on beta cell function when added to insulin therapy**J. Foley<sup>1</sup>, P. Kozlovski<sup>2</sup>, V. Lukashevich<sup>1</sup>, W. Kothny<sup>1</sup>;<sup>1</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA, <sup>2</sup>Novartis Pharma AG, Basel, Switzerland.

**Background and aims:** Vildagliptin increases glucose (GLU) sensitive insulin (INS) secretion and decreases INS sensitive glucagon secretion; these effects are considered acute (i.e. direct drug effects). In a 24-week randomized, double-blind, placebo-controlled study, vildagliptin 50mg bid showed significant improvement in glycemic control in patients with type 2 diabetes inadequately controlled on stable dose of basal or premixed INS, with or without concomitant metformin (MET) treatment compared to placebo. One of the study objectives was to evaluate the chronic effect of vildagliptin on beta-cell function and INS sensitivity in this patient population; after 24 weeks of treatment these parameters were measured in the absence of INS, vildagliptin and MET.

**Materials and methods:** GLU and INS response were assessed during a 2 hour OGTT performed at baseline, and after 24 weeks of treatment. Patients did not take their study medication, INS injection, and MET (if applicable) on the morning of the OGTT. INS secretion rate relative to GLU (ISR/G), and oral GLU INS sensitivity (OGIS) index were determined, using the measurements of fasting (time 0), 15, 30, 60, 90 and 120 minute plasma GLU, C-peptide and INS levels. The change from baseline to study endpoint (data censored prior to major change in INS, up to week 24) in the full analysis set was analyzed using analysis of covariance (ANCOVA) model.

**Results:** The increase in ISR/G from baseline to study endpoint in the vildagliptin group was larger than in the placebo group with statistically significant difference between treatments (Table 1). Small increases from baseline to endpoint (approximately 5%) in OGIS were observed in both treatment groups with no difference between treatment groups.

**Conclusion:** Vildagliptin added to stable dose of basal or premixed INS, with or without concomitant MET treatment, improves a chronic effect on beta-cell function. This improved beta-cell function is presumably secondary to the known diverse acute pancreatic and non-pancreatic effects of vildagliptin. Table 1: ANCOVA results for change in ISR relative to glucose (0 - 2 hours) and change in OGIS index from baseline to study endpoint by treatment.

## 860

**Improved glycaemic control without increased hypoglycaemia incidence and weight gain with insulin-vildagliptin combination therapy in Asian patients with type 2 diabetes**P. Kozlovski<sup>1</sup>, J. Foley<sup>2</sup>, Q. Shao<sup>2</sup>, V. Lukashevich<sup>2</sup>, W. Kothny<sup>2</sup>;<sup>1</sup>Novartis Pharma AG, Basel, Switzerland, <sup>2</sup>Novartis Pharmaceutical Corporation, East Hanover, USA.

**Background and aims:** The diabetes epidemic in Asia is characterised by rapid growth, onset at a relatively young age and low BMI. Approximately 25% of patients are treated with insulin, however their glycaemic control remains unsatisfactory and the fear of hypoglycaemia remains a barrier for its improvement. Vildagliptin (VILDA) is a dipeptidyl peptidase-4 inhibitor with proven efficacy and low risk of hypoglycaemia in monotherapy and in com-

bination with oral antidiabetic drugs (OADs) and insulin (INS). Considering the specifics of the pathophysiology of type 2 diabetes (T2DM) in Asians, it is of interest to characterise the response to VILDA therapy when combined with insulin in this population.

**Materials and methods:** VILDA 50 mg bid added to INS with or without concomitant metformin therapy was studied in a 24-week, global, randomised, double-blind, placebo-controlled study. We present a post-hoc analysis of 173 Asian patients with T2DM who participated in this study (38.5% of the overall study population). Change in efficacy endpoints, HbA1c and fasting plasma glucose (FPG), from baseline to study endpoint were analysed using an analysis of covariance (ANCOVA) model. Change from baseline to endpoint in body weight was summarised by treatment. Safety and tolerability of VILDA were also evaluated.

**Results:** Patients were 54.5 years old, with T2DM duration of 11.6 years and BMI 26.4 kg/m<sup>2</sup>. They were treated with premixed INS (63.6%), long-acting INS (12.7%) and intermediate-acting INS (23.7%). The mean duration of INS use was 3.6 years and the mean dose was 39.5 U/day. Sixty percent of patients were also receiving stable metformin dose ≥1500 mg. Eighty-seven patients were receiving VILDA and 86 patients were receiving placebo. The between treatment difference in HbA1c was 0.82% (p<0.001) in favor of VILDA. There was no significant difference in the change in FPG between treatments (Table 1). The weight was stable in both treatment groups (change from baseline to endpoint 0.3 kg and -0.2 kg, for VILDA and placebo, respectively). Overall VILDA was safe and well tolerated. Incidences of hypoglycaemia were similarly low (8.0% vs 8.1%) and no severe hypoglycaemic events were experienced in either of the groups.

**Conclusion:** In Asian patients inadequately controlled with INS (with or without concomitant metformin), INS-VILDA combination treatment resulted in a significant reduction in HbA1c compared to placebo. This improvement in glycaemic control did not put patients at additional risk of hypoglycaemia or weight gain. These findings are in line with the results of the overall population in the study. INS-VILDA combination can be a suitable treatment regimen in Asian patients taking INS who do not achieve glycaemic target.

**Enhanced beta cell function after chronic treatment with the dipeptidyl peptidase-4 inhibitor Vildagliptin in an advanced age diet-induced obesity mouse model**

B. Omar, J. Vikman, M.S. Winzell, B. Åhrén;

Clinical Sciences, Lund University, Sweden.

**Background and aims:** Treatment of type 2 diabetes with dipeptidyl peptidase-4 (DPP-4) inhibitors has a potential for long-term effects on beta cell function, since DPP-4 inhibitors, as well as glucagon-like peptide-1 (GLP-1), the level of which is increased during this treatment, have been shown to increase beta-cell mass in various rodent models. However, these models have been of short duration allowing effects only during up to 10 weeks to be examined and treatment has usually commenced in young animals, which is far from the clinical situation. Therefore, more appropriate pre-clinical models are needed for the studies on long-term effects and for development of improved incretin based therapies.

**Materials and methods:** We have generated a diet induced obesity (DIO) model in advanced aged mice, to more accurately represent the time at which

hyperglycemia debuts in humans, and treated the mice with DPP-4 inhibition over a very long time. C57BL/6J mice were 10 months old at the start of high fat diet (HFD) feeding and received the high fat diet for 12 months. After one month of HFD alone, a subgroup of mice were treated with the DPP-4 inhibitor vildagliptin (3μmol/day in the drinking water), in addition to the HFD, for a period of 11 months. Control HFD mice were given normal drinking water, and the protocol also included a series of mice given normal chow throughout with or without treatment with vildagliptin. Oral glucose tolerance tests (OGTT) were administered at the start of and at 2, 5, 8 and 11 months after the start of vildagliptin treatment. At termination pancreata were excised for measurement of beta cell mass.

**Results:** Fasting glucose was reduced by vildagliptin treatment in HFD fed animals by the end of the 11 month study period ( $8.6 \pm 0.5\text{mM}$  at start v.  $6.8 \pm 0.5\text{mM}$  at 11 months after start of therapy,  $p < 0.05$ ) whereas no such reduction was observed in controls. Furthermore, HFD fed mice treated with vildagliptin had lower plasma glucose levels after an OGTT than untreated mice after two months of treatment ( $p < 0.05$ ) and glucose levels decreased continually thereafter until the end of the study period ( $p < 0.001$  at 5 and 11 months after start). Insulin secretion in response to the OGTT was increased in the HFD fed, vildagliptin treated mice after two months of treatment ( $p < 0.01$ ) and remained elevated during the 11 month study period ( $p < 0.001$  at 5 and 11 months). Beta cell function was improved by vildagliptin treatment in both diet groups at each time point throughout the course of the study ( $p < 0.001$  for all time points). In HFD fed mice, HOMA-IR was significantly lower in the vildagliptin treated group after 2 months of treatment compared to the untreated group ( $p < 0.05$ ), there were no significant differences between the groups at later time points. Despite increases in beta cell function, beta cell mass was not significantly altered by long-term vildagliptin treatment in advanced age mice in either diet group. Finally, there were no differences in weight gain between untreated and vildagliptin treated mice in either diet group.

**Conclusion:** In a unique advanced age DIO model with regular testing of islet function throughout the very old age of 21 months, insulin secretion, insulin sensitivity and beta cell function, but not mass, was improved by chronic vildagliptin treatment in HFD fed mice, and the improvements lasted over the lifetime of the experimental mice. This shows that DPP-4 inhibition has the potential of improve beta cell function over a long-term period.

**Vildagliptin more effectively achieves a composite endpoint of HbA<sub>1c</sub> <7% without hypoglycaemia or weight gain compared with SUs: a pooled analysis of clinical trials**

G. Bader, A. Schweizer;  
Novartis Pharma AG, Basel, Switzerland.

**Background and aims:** Previous studies have shown that vildagliptin as add-on therapy to metformin in patients with type 2 diabetes mellitus (T2DM) has similar efficacy on HbA<sub>1c</sub> as sulfonylureas (SUs). In this pooled analysis, we aimed to measure the overall clinical benefit of vildagliptin compared with SUs by assessing the number of patients reaching a composite endpoint of HbA<sub>1c</sub> <7%, no hypoglycaemia (symptoms and plasma glucose <3.1 mmol/L), and no weight gain (<3%). We also investigated whether there were differences in reaching the composite endpoint in relationship to age of patients and/or duration of diabetes.

**Materials and methods:** Data were pooled from two add-on to metformin studies ( $n = 3033$ ) comparing vildagliptin ( $n = 1541$ ) with SUs (glimepiride and gliclazide,  $n = 1492$ ). The relative success rate (SR) was calculated by taking the ratio of the number of patients achieving composite endpoint in vildagliptin and SU groups.

**Results:** The overall baseline HbA<sub>1c</sub> was 7.9% for both vildagliptin and SUs. After 52 weeks, a higher proportion of patients reached the composite endpoint in the vildagliptin group (32.3%) than in the SU group (21.9%). The overall SR of vildagliptin compared with SUs, along with the relative SR with respect to age of patients or duration of diabetes is presented in the table.

**Conclusion:** This pooled analysis shows that vildagliptin as add-on therapy to metformin demonstrated a better clinical benefit - as defined by the composite endpoint of reaching HbA<sub>1c</sub> <7%, with no hypoglycaemia and no weight gain - than SUs added to metformin after 52 weeks of treatment, regardless of age of patients or duration of diabetes.

Success rate (HbA <sub>1c</sub> <7%, no hypos, no weight gain)			
	Vildagliptin n/total (%)	SU n/total (%)	Vildagliptin vs. SU Relative SR (95% CI)

**Effectiveness and safety of vildagliptin compared with other oral antidiabetic drugs in patients with type 2 diabetes: results from a large worldwide cohort study (EDGE)**

C. Mathieu<sup>1</sup>, G. Bader<sup>2</sup>, N. Hagner on behalf of EDGE Steering Committee<sup>3</sup>;

<sup>1</sup>Experimental Medicine and Endocrinology Section, Catholic University of Leuven, Belgium, <sup>2</sup>Novartis Pharma AG, Basel, Switzerland, <sup>3</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA.

**Background and aims:** While metformin is an established first line treatment for patients with type 2 diabetes mellitus (T2DM), intensification of therapy with combinations is typically required over time. The purpose of the Effectiveness of Diabetes control with vildaGliptin and vildagliptin/mEtformin (EDGE) study is to compare prospectively the effectiveness and safety of vildagliptin with other oral antidiabetic drugs (OADs) in patients with T2DM inadequately controlled by monotherapy, in real life conditions across 5 regions worldwide (East Asia, Europe, Latin America, India, Middle East).

**Materials and methods:** Patients became eligible only after the add-on treatment was chosen by the physician based on the patient need and were assigned to one of two cohorts: (i) vildagliptin or (ii) other OADs including any sulfonylurea, thiazolidinedione, glinide, or α-glucosidase inhibitor or metformin but excluding any DPP-4 inhibitor or GLP-1 mimetics/analogues. The effectiveness was assessed by means of a composite endpoint including the proportion of patients responding to treatment (HbA<sub>1c</sub> drop >0.3%) without peripheral edema or proven hypoglycemic event or discontinuation due to gastrointestinal (GI) event or significant weight gain (≥5%) after 12 months of treatment.

**Results:** Overall, 45868 patients in 27 countries across the world were enrolled and assigned to a treatment cohort ( $N=29759$  in vildagliptin and  $N=16078$  in the comparator cohort), of which 31 patients were not assigned to any cohort. The mean baseline HbA<sub>1c</sub> was 8.2% in both cohorts. The probability of success [analysed using a multivariable logistic regression model to calculate odds ratios (OR) adjusted for potential confounders (baseline age, HbA<sub>1c</sub>, BMI, gender, region, co-morbidities, co-treatments)] was higher for vildagliptin, overall and in every region regardless of baseline HbA<sub>1c</sub> and second drug chosen by the physician in the comparator arm. Overall, 55.4% and 51.3% of patients in the vildagliptin and comparator cohorts, respectively, had decrease in HbA<sub>1c</sub> >0.3% without peripheral edema, hypoglycemia, GI events and weight gain after 12 months of treatment (Unadjusted OR 1.18 [95% CI: 1.13; 1.22]). Overall, 2383 (5.44%) adverse events were reported: 1503 (5.28%) in vildagliptin and 880 (5.73%) in the comparator cohort.

**Conclusions:** In real life setting, the proportion of patients responding to treatment (HbA<sub>1c</sub> drop >0.3%) without tolerability issues (hypoglycemia, weight gain, GI events and peripheral edema) was higher in the vildagliptin than in the comparator cohort in every region of the world considered, regardless of HbA<sub>1c</sub> at the baseline or drug added to the monotherapy. The proportion of reported adverse events was similar in the two cohorts.

	Vildagliptin N=28061	Comparator N=15294	Odds Ratio (95% CI)
Overall adjusted	15536/12525	7852/7442	1.49 (1.42, 1.55)
East Asia	438/1206	183/547	1.09 (0.89, 1.33)
Europe	7542/7764	3002/3457	1.12 (1.06, 1.19)
Latin America	1810/1192	391/380	1.48 (1.26, 1.73)
Middle East	1904/599	1394/870	1.98 (1.75, 2.25)
India	3842/1764	2882/2188	1.65 (1.53, 1.79)
Sulfonylureas	15536/12525	4179/3809	1.13 (1.08, 1.19)

## 864

### Factors contributing to the glucose-lowering effect of vildagliptin identified from the results of the OGTT in Japanese patients with type 2 diabetes

A. Nakamura, Y. Terauchi;

Department of Endocrinology and Metabolism, Graduate School of Medicine, Yokohama City University, Japan.

**Background and aims:** Several clinical trials have shown the efficacy of vildagliptin in patients with type 2 diabetes. Although OGTT is simpler, less time-consuming and less expensive to perform than the intravenous test or tracer tests, and is often used in intervention studies, the efficacy of vildagliptin has not yet been adequately examined by OGTT. Here, in order to investigate the factors contributing to the glucose-lowering effect of vildagliptin, we analyzed the results of OGTT together with several clinical parameters in Japanese patients with type 2 diabetes before and after 24 weeks of treatment with vildagliptin.

**Materials and methods:** After obtaining the approval of the institutional review board and written informed consent from the patients, we analyzed several clinical parameters, including HbA1c and body weight before and after 24 weeks of treatment with vildagliptin at 100 mg/day. Also, the plasma glucose and insulin were measured after an overnight 12-h fast and during a 75-g OGTT at 30, 60, 90 and 120 min before and after 24 weeks of treatment with vildagliptin.

**Results:** The data of the 13 patients who satisfactorily completed the follow-up examinations were included in the analysis. The mean age was  $68.9 \pm 6.7$  years. At baseline, the mean fasting plasma glucose was  $156.9 \pm 39.0$  mg/dl, HbA1c was  $7.2 \pm 0.5\%$ , and BMI was  $22.4 \pm 3.3$ . After 24 weeks treatment with vildagliptin, the patients were classified into a responder group (9/13; 69.2%) and a non-responder group (4/13; 30.8%); the responders consisting of subjects whose HbA1c decreased following 24 weeks treatment with vildagliptin, and the non-responders consisting of subjects who did not show any significant decrease of HbA1c. There were no differences in baseline characteristics between the two groups before administration of vildagliptin. After 24 weeks of treatment, HbA1c was significantly reduced from  $7.3 \pm 0.5\%$  to  $6.7 \pm 0.5\%$  in the responder group ( $P = 0.0077$ ), while it tended to rather increased from  $7.1 \pm 0.6\%$  to  $7.5 \pm 0.7\%$  in the non-responder group ( $P = 0.0679$ ). There were no differences in the degree of the body weight between the two groups. Next, we compared some parameters, including the insulin secretion and insulin sensitivity as estimated by the OGTT between the two groups before and after 24 weeks of treatment with vildagliptin. There were no differences in these parameters between the two groups before the start of administration of vildagliptin. Of note, while Matsuda index and HOMA-IR were similar in the two groups after treatment of vildagliptin, the insulinogenic index and oral disposition index were significantly higher in the responder group than in the non-responder group (insulinogenic index:  $0.27 \pm 0.22$  in the responder group versus  $0.07 \pm 0.01$  in the non-responder group ( $P = 0.0308$ ); oral disposition index:  $1.12 \pm 1.11$  in the responder group versus  $0.30 \pm 0.15$  in the non-responder group ( $P = 0.0087$ )). By contrast, the insulin/glucose ratio at 30 min and the HOMA- $\beta$  were indistinguishable between the two groups after vildagliptin treatment.

**Conclusion:** Although further large-scale randomized controlled studies are needed to obtain more detailed information, our results suggest that the difference in the degree of improvement of the glucose tolerance between the

responder group and the non-responder group was caused by the effect of vildagliptin on the insulin secretory capacity, but not on the insulin sensitivity.

## 865

### Efficacy and tolerability of vildagliptin as an add-on to nateglinide in Japanese patients with type 2 diabetes mellitus

K. Fujimaki, T. Hirose, Y. Someya, T. Yoshihara, Y. Fujitani, H. Watada; Metabolism & Endocrinology, Juntendo University Graduate School of Medicine, Bunkyo-ku, Japan.

**Background and aims:** Vildagliptin improves glycemic control in patients with type 2 diabetes mellitus (T2DM) either as monotherapy or in combination with other oral hypoglycemic drugs or insulin. In addition, vildagliptin is weight neutral and is associated with minimal risk of hypoglycemia either as monotherapy or in combination with metformin or TZD. There has been no report that shows the efficacy of vildagliptin in combination with insulin secretagogue, glinide in type 2 diabetes patients, previously. To investigate the efficacy and tolerability of vildagliptin, a potent and selective eptidyl peptidase-4 inhibitor, as add-on to nateglinide in Japanese type 2 diabetes patients controlled inadequately.

**Materials and methods:** Forty patients inadequately controlled with nateglinide (range of HbA1c was 6.9–8.4% and mean duration of use was 12 months) were randomized 1:1 to switch from nateglinide to vildagliptin (50mg twice daily, n=20: V group) or vildagliptin as add-on therapy to nateglinide (50mg of vildagliptin twice daily and 90 mg of nateglinide thrice daily, n=20: C group). Patients underwent a meal tolerance test on 90 mg nateglinide alone at weeks 0 and on 50 mg vildagliptin alone or on 50 mg vildagliptin in combination with 90 mg nateglinide at weeks 24.

**Results:** Treatment groups were balanced at baseline (glycosylated hemoglobin [HbA1c (NGSP)], 7.5%; fasting plasma glucose, 8.5mmol/L). The mean changes from baseline HbA1c to week 24 endpoint were  $-1.2 \pm 0.3$  and  $-0.3 \pm 0.5\%$  in patients of C group and V group respectively ( $P < 0.001$ ). The mean changes of glucose AUC<sub>0-180</sub> was  $-140.6 \text{ mmol} \cdot \text{min/L}$  in patients of V group compared to  $-361.2 \text{ mmol} \cdot \text{min/L}$  in those of C group ( $P < 0.001$ ). The difference between the treatment groups in HOMA- $\beta$  and HOMA-R were not significantly different. The AUCs of insulin from 0 to 180 decreased from baseline to endpoint in both groups, while there were no significant differences between the two groups (mean change  $\pm$  standard deviation [SD] =  $-518 \pm 1428 \mu\text{U} \cdot \text{min/ml}$  in patients of C group and  $-893 \pm 1808 \mu\text{U} \cdot \text{min/ml}$  in those of V group, respectively). The AUCs of insulin from 0 to 30 in the V group significantly reduced compared to the C group (mean change  $\pm$  SD =  $-35 \pm 328 \mu\text{U} \cdot \text{min/ml}$ ,  $+42.6 \pm 320 \mu\text{U} \cdot \text{min/ml}$ , respectively,  $P < 0.001$ ). Body weight at baseline was similar between the treatment groups. Body weight increased from baseline to endpoint in both groups, with greater changes observed in the C group compared to the V group (mean change  $\pm$  SD =  $+1.0 \pm 1.7$  and  $+0.4 \pm 1.6 \text{ kg}$ , respectively,  $P = 0.216$ ), but the difference was not statistically significant. There were no serious adverse events during the treatment period except three episodes of mild hypoglycemia in the C group. These symptoms were disappeared after dose reduction of nateglinide.

**Conclusion:** Vildagliptin 50mg twice-daily is effective and well tolerated as an add-on to nateglinide in Japanese patients with T2DM, with no significant weight gain and a severe hypoglycemia.

## PS 069 Screening, prevention and early management

866

### Development and evaluation of screening score for detecting undiagnosed diabetes and estimating absolute risk of future type 2 diabetes: TOPICS

Y. Heianza<sup>1,2</sup>, S. Hara<sup>2</sup>, S. Yoshizawa<sup>1</sup>, K. Kodama<sup>1,2</sup>, K. Saito<sup>1,2</sup>, S.D. Hsieh<sup>2</sup>, C. Horikawa<sup>1</sup>, H. Tsuji<sup>2</sup>, N. Yamada<sup>1</sup>, Y. Arase<sup>2</sup>, H. Sone<sup>1,2</sup>;

<sup>1</sup>Department of Endocrinology and Metabolism, University of Tsukuba Mito Medical Center, Mito, <sup>2</sup>Health Management Center, Toranomon Hospital, Tokyo, Japan.

**Background and aims:** Whether a screening questionnaire eliciting information on non-invasive clinical markers to detect undiagnosed diabetes would also accurately assess the absolute risk of future diabetes remains unknown. We developed a screening score for undiagnosed diabetes and assessed its effectiveness for both identifying the presence of diabetes and predicting future onset of diabetes.

**Materials and methods:** A total of 33335 Japanese individuals aged 18–88 y without a self-reported history of diabetes comprised the cohort for development of the screening score. We prospectively followed 7332 non-diabetic individuals who received re-examinations at 2 and 4 years after the initial assessment by the developed screening score. The absolute risk of developing diabetes was estimated according to screening scores.

**Results:** Prevalence of undiagnosed diabetes (fasting plasma glucose  $\geq 7.0$  mmol/L or HbA<sub>1c</sub>  $\geq 6.5\%$ ) was 2.9% (n=965). The diabetes score included age, sex, family history of diabetes, current smoking habit, body mass index and hypertension. At the optimal cut-off value of 8 points, sensitivity was 72.7% and specificity was 68.1%. Although only 6.4% of individuals detected by the screening (n=11024) actually had diabetes, 45.7% were in a pre-diabetic state. Results of Kaplan-Meier analysis demonstrated that the absolute risk for the development of diabetes gradually escalated with increases in scores (log-rank testing,  $p < 0.001$ ). Screening test results of  $< 4$ , 4–5, 6–7, 8–9 and  $\geq 10$  points at the initial examination estimated 4-y cumulative probabilities of 0.1%, 0.9%, 2.3%, 4.2% and 8.4%, respectively, for the development of future diabetes. A substantially increased risk of developing diabetes was observed for a score of 8–9 points (incidence rate, 12.6/1000 person-years) and  $\geq 10$  points (23.3/1000 person-years) than that for lower scores or that for the total subject population. Hazard ratios (HRs) for the development of diabetes were significantly higher for individuals with scores of 8–9 points (HR 1.83, 95% CI: 1.32–2.52) and scores of  $\geq 10$  points (HR 3.48, 95% CI: 2.49–4.88) compared to those with 6–7 point scores.

**Conclusion:** Prognostic information on the risk of developing diabetes could also be provided at initial screening for undiagnosed diabetes. Our study results will assist lay people in measuring their own risk of diabetes outside of clinical settings as well as targeting individuals who need to be followed to prevent new onset of the disease.

### Incidence of diabetes is reduced by low-intensity, community-based lifestyle intervention. Three-year results from the Greek arm of the DEPLAN study

A. Tsiakou, S. Liatis, C. Stathi, D. Perrea, S. Grammatikou, N. Katsilambros, K. Makrilakis;

First Department of Internal Medicine & Diabetes Center, Athens University Medical School Laiko Hospital, Greece.

**Background and aims:** It has been repeatedly shown that type 2 diabetes can be prevented or delayed by intensive lifestyle intervention in populations with impaired glucose tolerance. It is not clear, however, whether less structured, community-based interventions in individuals at high type 2 diabetes risk, are effective in preventing the disease, especially in the long-term. In the present analysis, three-year incidence of type 2 diabetes was examined in a group of high-risk individuals who participated in the Greek arm of a European type 2 diabetes prevention study (DEPLAN).

**Materials and methods:** High-risk individuals, identified by the FINDRISK score questionnaire, participated in a one-year lifestyle intervention programme, based on bimonthly, group (6–8 persons) sessions with a dietitian.

All sessions took place near the participants' residence or work-place. Glycaemic status was assessed at baseline and after three years (two years after the end of the intervention) by an OGTT. A control group comprised individuals who were also screened by OGTT at baseline and followed-up for three years, who were at lower risk or did not wish to participate in the intervention programme.

**Results:** Ninety-one persons (51 females, mean age: 54.6 [52.4–56.7] years), were included in the intervention group, while the control group comprised 168 individuals (81 females, mean age: 54.2 [52.6–55.8] years). The two groups had different baseline characteristics, the intervention group being at significantly higher risk than the controls (mean FINDRISK score: 17.4 [16.9–17.9] vs. 10.3 [9.7–10.9],  $p < 0.001$  and mean fasting plasma glucose (FPG): 103.8 [101.6–106.1] mg/dl vs. 96.9 [95.2–98.5] mg/dl,  $p < 0.001$ ). At three years, individuals in the intervention group showed a 1.22% [0.2–2.6] weight loss, vs. a 1.20% [0.4–2.1] increase in the control group ( $p = 0.003$ ). In addition, a significantly higher proportion of individuals in the intervention group lost  $> 5\%$  of their initial body weight (23.1% vs. 11.4%,  $p = 0.01$ ). Incidence of diabetes at three years was similar between the two groups: 11.0% in the intervention vs. 10.1% in the control group (OR: 1.1 [0.5–2.5],  $p = 0.82$ ). When adjusted, however, for baseline FINDRISK score and baseline FPG, the intervention turned out to be a significant protective factor for incident diabetes (OR: 0.15 [0.05–0.49],  $p = 0.002$ ).

**Conclusion:** A low-intensity, community-based lifestyle intervention of one-year's duration is protecting from incident diabetes after three years. A mild weight loss is still apparent two years after the end of the intervention.

### Physical activity in screen-detected patients with abdominal obesity and metabolic syndrome: at screening and three years thereafter

H. Jansen, C. den Engelsens, G.E.H. Rutten;

Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Netherlands.

**Background and aims:** Metabolic syndrome (MetS) is associated with an increased risk of developing type 2 diabetes and cardiovascular disease. An important way to prevent this is to decrease weight and increasing the level of physical activity (PA). Our aim was to investigate the change in level of PA in patients with screen-detected metabolic syndrome.

**Material and methods:** After a population-based screening, 1,721 patients with a self-measured increased waist circumference underwent a physical examination and laboratory assessment. Totally 473 were diagnosed with MetS (NCEP ATP III criteria) and 1,248 with abdominal obesity but without MetS. All screening participants were given the advice to contact their general practitioner. Patients with MetS received 'standard' care according to existing guidelines; deliberately no special intervention was developed. Three years after screening a random selection was invited for follow-up measurements. PA was measured by means of the validated SQUASH questionnaire. Primary outcome measure: % of people fulfilling Dutch Physical Activity Guideline (DPAG) criterion.

**Results:** Mean (SD) age of our study population was 48.3 (10.9) years. At screening 55.2% of the 473 patients with MetS fulfilled the DPAG criterion compared to 61.2% of the patients 1,248 without MetS ( $p = 0.03$ ). The percentage of patients fulfilling the DPAG criterion did not increase between screening and follow-up, neither in MetS patients (n=191; 52.4% vs. 58.5%,  $p = 0.16$ ) nor in patients without MetS (n=173; 63.4% vs. 63.6%,  $p = 1.00$ ). Mean (SD) waist circumference decreased in MetS patients who increased their level of PA (n=31; 102.6(8.6) vs. 100.1(10.1),  $p = 0.03$ ) as well as in those who did not (n=160; 105.5(9.6) vs. 101.7(11.4),  $p < 0.001$ ). Eleven patients started with glucose-lowering medication between screening and follow-up. Excluding these patients, mean (SD) fasting glucose increased in MetS patients who increased their level of PA (n=26; 5.0(0.6) vs. 5.2(0.6),  $p = 0.005$ ), as well as in those who did not (n=155; 5.1(0.6) vs. 5.4(0.7),  $p < 0.001$ ).

**Conclusion:** Screen-detected patients with MetS are less physically active compared to patients without MetS. Most MetS patients do not increase their level of PA after being diagnosed with MetS and receiving usual care in a primary care setting. More effort is needed to activate these patients to prevent future diabetes.

## 869

**Genetic variation in the fat mass and obesity-associated gene (FTO) could influence food preference in adults**L. Brunkwall<sup>1</sup>, U. Ericson<sup>1</sup>, S. Hellstrand<sup>1</sup>, B. Gullberg<sup>2</sup>, M. Orho-Melander<sup>1</sup>, E. Sonestedt<sup>1</sup>;<sup>1</sup>Clinical Sciences, Diabetes and Cardiovascular Disease, Genetic Epidemiology, <sup>2</sup>Clinical Sciences, Nutritional Epidemiology, Malmö, Sweden.

**Background and aims:** Studies have indicated that the FTO genotype is not only associated with BMI and weight but also with dietary intake. Our aim was to investigate if FTO genotype (rs9939609) associates with food preferences. Additionally we examined the association separately in lean and overweight individual's challenging the question if the associations could be modified by obesity status.

**Materials and methods:** Analyses were performed among 22,799 adults from the population based Malmö Diet and Cancer Study cohort. All individuals had complete dietary data, information about the FTO genotype (rs9939609) and no history of cancer, diabetes or CVD. For analyses of food preferences we used 27 food groups estimated with a 168-item questionnaire and a 7-day menu book.

**Results:** After correcting for multiple testing we observed a significant difference for reported intake of cakes and soft drinks across the FTO genotypes (P for trend <0.0001 for both) where the A-allele carriers that are more susceptible for obesity reported lower consumption of soft drinks but higher consumption of cakes than the TT carriers. Nominal differences were seen for fruits, cereals, high fat meat, ice cream and cheese where the risk allele carriers indicated a higher consumption. These observations remained similar after excluding the potentially inadequate energy reporters. In contrast to our hypothesis the results did not differ depending on obesity status.

**Conclusion:** We observed an association between the variation in the FTO genotype and food preferences in healthy adults.

**Prevention of type 2 diabetes with Mediterranean diet. Preliminary results from the first year of intervention of the Egabro-Pizarra study**S. Valdés<sup>1</sup>, M. Corpas<sup>2</sup>, M. Leña<sup>1</sup>, E. Rubio-Martín<sup>1</sup>, S. Morcillo<sup>1</sup>, F. Lima-Rubio<sup>1</sup>, A. Chicano<sup>1</sup>, G. Martín<sup>1</sup>, N. Porras<sup>1</sup>, J. Gómez-Zumaquero<sup>1</sup>, F. Sorriquer<sup>1</sup>, G. Rojo-Martínez<sup>1</sup>;<sup>1</sup>Endocrinology and Nutrition, Hospital Universitario Carlos Haya, IBIMA, CIBERDEM, Málaga, <sup>2</sup>Endocrinology and Nutrition, Hospital Universitario Reina Sofia, Cordoba, Spain.

**Background and aims:** Type 2 diabetes (DM2) represents one of the greatest health problems in our time. Its increasing proportions are especially worrisome in the south of Spain. The only alternative to stop the increasing incidence is prevention. The aim of this study is to test if an intervention program based on changes in lifestyle according to the Mediterranean diet pattern may: 1- prevent the incidence of type 2 diabetes in at least 50% and 2- reverse newly diagnosed diabetes in a semi-urban population of Andalusia (South of Spain). Another objective is to detect which factors influence the success of the intervention.

**Materials and methods:** Population-based cohort study including 320 subjects selected from the general population of two semi-urban towns of the south of Spain (Cabra and Pizarra) after performing an OGTT showing some glucose disturbance: Impaired fasting glucose (IFG) and / or impaired glucose tolerance (IGT) or undiagnosed diabetes. Individuals in the Cabra cohort (n=160) were included in an intensive lifestyle program with regular visits to achieve goals for dietary habits, exercise and weight within the Mediterranean dietary pattern (Intervention group). Individuals in the Pizarra cohort (n=160) were referred to their usual physicians with standard recommendations on lifestyle changes (Control group).

**Results:** After one year follow-up, diabetes developed in 9.1% of individuals with IFG and / or IGT in the control group compared to 4.7% in the intervention group (p<0.01). In this group, 60% had a complete reversion of glucose disturbance (compared to 47% in the control group). Of those with newly diagnosed diabetes, 46.7% reverted to either IFG/IGT or normal in the control group versus 73% in the intervention group (p<0.01). The intervention had strong effects on glucose and anthropometry measurements. No baseline anthropometric variable predicted the effect of treatment or the evolution of the subject within the year but Improving blood glucose was associated with weight loss during monitoring period.

**Conclusion:** After one year of intervention, we have shown that hyperglycemia (even at diabetic level) can be normalized without medication through changes in lifestyle following the Mediterranean diet pattern.

## 871

**Influence of working status on diabetes control - data from the PROGENS study**E. Franek<sup>1</sup>, A. Milczarczyk<sup>1</sup>, B. Mospan<sup>2</sup>, A. Sienkiewicz<sup>3</sup>, A. Zonenberg<sup>4</sup>, P. Bijos<sup>5</sup>, on behalf on PROGENS Study investigators;<sup>1</sup>Dept of Internal Diseases, Endocrinology and Diabetology, Central Clinical Hospital MSWiA, Warsaw, <sup>2</sup>Diabetology and Diabetic Foot Center, Zielona Gora, <sup>3</sup>Diabetes Center, Kolobrzeg, <sup>4</sup>Diabetes Center, Białystok, <sup>5</sup>Bioton SA, Warsaw, Poland.

**Background and aims:** Work may change the daily life habits, like eating time and volume. The aim of the present study was to answer the question whether those changes are significant and do influence diabetes control.

**Materials and methods:** To answer this question a subanalysis of data from the PROGENS study (multicenter observational study assessing effectiveness and safety of recombinant human insulin manufactured by Bioton, Poland) was performed. In this subanalysis 866 working (338F, 528M, W-group) and 1089 non-working patients with type 2 diabetes (743F, 346M, NW-group) were included (mean age 56±7 vs. 69±7y, p<0.001, mean BMI 30.3±4.8 vs. 30.8±4.7, NS, respectively). Four-points glycemic profiles, HbA1c and insulin doses were compared between those 2 groups. In a subset of 425 patients it was also compared whether there are differences in meal time and volume as well as fasting and postprandial glycemia between working and non-working patients on working and free days.

**Results:** The average daily insulin dose was similar in the both groups at study start (W 0.43±0.24 vs NW 0.45±0.23 U/kg/day, NS) as well as at the end (W 0.48±0.25 vs. NW 0.49±0.24 U/kg/day, NS). HbA1c decreased significantly during the study period (6 months) in both groups (W 8.3%±1.4 vs. 7.4%±0.9, p<0.001, NW 8.1%±1.1 vs. 7.3%±0.8, p<0.001). Similarly, significant decrease of fasting (W 169±33 vs. 140±20 mg/dl, p<0.001, NW 167±31 vs. 142±23 mg/dl, p<0.001). No significant differences in the volume and time of meals were observed, as well as no clinically meaningful differences of fasting and postprandial glucose concentrations. Working patients however eat their breakfast on average half an hour earlier (7.37±0.52 vs. 08.01±0.47, p<0.001), and their dinners have more often greater volume on working days as compared with free days (phi correlation 0.529, p<0.001). These differences however did not influence glycemic control. There were also no differences in hypoglycemia rate between working and non-working patients on working and free days. The frequency of hypoglycemia was however very small.

**Conclusion:** The differences in volume and time of meals caused by daily working schedule are slight and did not influence diabetes control in a clinically meaningful way.

## 872

**SLC47A1 gene rs2289669 G>A variant influences plasma lactate concentrations in metformin-treated type 2 diabetes mellitus**F. Liu<sup>1,2</sup>, Y. Shen<sup>1</sup>, T. Zheng<sup>1,3</sup>, J. Tang<sup>1,3</sup>, W. Jia<sup>1,4</sup>;<sup>1</sup>Endocrinology and Metabolism, Shanghai Clinical Medical Center of Diabetes, <sup>2</sup>Shanghai Jiaotong University-affiliated Sixth People's Hospital, <sup>3</sup>Shanghai Key Laboratory of Diabetes, <sup>4</sup>Shanghai Jiaotong University Affiliated Sixth People's Hospital, China.

**Background and aims:** The SLC47A1 gene encodes for multidrug and toxin extrusion 1 (MATE1) which plays a pivotal role in the metabolism and excretion of metformin. The present study is to investigate the relationship between the SLC47A1 gene polymorphism and plasma lactate levels in Chinese Hans who suffered from type 2 diabetes mellitus (T2DM) with and without metformin therapy.

**Materials and methods:** The SLC47A1 single nucleotide polymorphism (SNP) rs2289669 G/A was genotyped in 287 T2DM patients, including a metformin treated group (n = 151) and a non-metformin-treated group (n = 136) with PCR-restriction fragment length polymorphism method. Fasting plasma lactic acid levels were measured with an enzyme electrode assay.

**Results:** Three SLC47A1 genotypes, GA, GG and AA were found in T2DM patients of Chinese Hans. The frequency of the SLC47A1 rs2289669 G/A and A allele was 50.6%. The metformin group had higher plasma lactate concentration than the non-metformin group ( $1.15 \pm 0.36 \text{ mmol/L}$  vs  $1.01 \pm 0.37 \text{ mmol/L}$ ,  $P=0.002$ ). Patients with the mutant genotype (AA) had a higher blood lactate concentration in the metformin group than those in the non-metformin group ( $1.26 \pm 0.40 \text{ mmol/L}$  vs  $0.94 \pm 0.27 \text{ mmol/L}$ ,  $P=0.001$ ), whereas there were no obvious differences of lactate levels in patients with GA, GG genotype between the two groups. Female patients with the AA genotype had higher lactic acid concentrations ( $1.26 \pm 0.35 \text{ mmol/L}$ ) than males ( $0.99 \pm 0.36 \text{ mmol/L}$ ) with AA genotype ( $P=0.008$ ). However, there were no gender difference of lactate levels in patients with GA, GG genotype ( $P=0.061$ ,  $P=0.236$ , respectively) in total patients. In the metformin-treated group, there were significant gender differences in lactate concentrations carried with AA genotype ( $1.43 \pm 0.33$  in women vs  $1.12 \pm 0.41 \text{ mmol/L}$  in men,  $P=0.041$ ) but not with GG, GA genotype. The lactate levels of women with the AA genotype were the highest ( $1.43 \pm 0.33$  vs  $1.19 \pm 0.32$  and  $1.09 \pm 0.24 \text{ mmol/L}$ ,  $P=0.021$ ). But differences in lactate levels among the three genotypes were not observed in non-metformin group ( $P>0.05$ ).

**Conclusion:** The SLC47A1 gene rs2289669 G>A variant influences the plasma lactate concentrations in T2DM patients with metformin therapy. Lactic acid levels of female patients with AA genotype are more likely to elevate.

### Increased lean body mass significantly improves bone health in type 2 diabetes mellitus

I. Maisnam, D. Dutta, A. Shrivastav, S. Ghosh, S. Mukhopadhyay, S. Chowdhury;  
Endocrinology and Metabolism, Institute of Post-graduate Medical Education and Research, Kolkata, India.

**Background and aims:** Bone mass in type 2 diabetes may be low, high or similar compared to general population. High BMI and hyperinsulinemia may increase bone mass. Adiposity seen in type 2 diabetes is associated with increase cytokines, vitamin D deficiency and may affect bone health. Lean body mass may bear a positive correlation with bone health, and fat mass may have a negative correlation. The aim was to determine the correlation between body mass, body mass composition, fat distribution and bone mineral content and density; and vitamin D levels in type 2 diabetes.

**Materials and methods:** This was a cross-section study of type 2 diabetes, age 35–55 years from our diabetic clinic from December 2011 to December 2012. Post-menopausal women, prolonged immobilization, advanced kidney and liver disease, cancers, rheumatologic conditions, pregnancy, prolonged corticosteroid use were excluded. BMI  $\geq 25$  was obese based on the Indian criteria. DEXA measured bone mineral density (BMD) ( $\text{g/cm}^2$ ), bone mineral content (BMC), fat mass, lean mass, and percent body fat, android and gynoid fat with a Lunar DPX NT densitometer. 25(OH) vitamin D level was measured by chemiluminescent microparticle assay. Levels  $< 20$ ,  $20$ – $30$ ,  $> 30 \text{ ng/ml}$  were deficient, insufficient and sufficient respectively. Statistical analysis was done using SPSSv16 software. Comparison was done using one way ANOVA. Pearson's correlation coefficient was used to compare 2 variables. A  $p$  value  $< 0.05$  was considered significant.

**Results:** There were 40 females and 48 males, mean age  $40.7 \pm 5.1$  and  $47.4 \pm 5.8$  respectively. 30, 40 and 18 patients were vitamin D deficient, insufficient and sufficient respectively. A significant ( $p=0.009$ ) correlation between the BMC and the BMI ( $r=0.457$ ) was seen. A very significant ( $p<0.001$ ) strong correlation between bone mineral content and lean mass ( $r=0.847$ ) was seen, this persisted after adjusting for vitamin D levels ( $r=0.85$ ,  $p<0.001$ ). A significant fair correlation existed between BMC and fat mass ( $r=0.41$ ,  $p=0.019$ ). Lumbar spine BMD had a significant correlation with lean and fat mass ( $r=0.42$ ). Fat percent was higher, lean mass lower, BMC, BMD was lower in vitamin D deficient, but not significant. Calcium was significantly lower in the deficient group. No significance difference in HbA1c, LDL and HDL in 3 vitamin D groups. Favourable findings were seen in vitamin D sufficient and the insufficient, but not deficient groups.

**Conclusion:** Increased BMC and BMD were associated with increased lean body mass, fat mass also contributed. The association persisted after adjusting for vitamin D levels. Though insignificant, vitamin D was lower with higher fat mass and lower lean mass. Higher vitamin D was associated with higher BMD in the femur (almost significant). There was no relation between vitamin D status and glycemia. Increase lean mass is needed for good bone health

in type 2 diabetes. Adipose tissue mass which is associated with lower vitamin D levels should be decreased.

Vitamin D status, body fat composition, bone mineral content, dyslipidaemia and glycaemia

Parameter	vitamin D <20ng/ml	vitamin D 20–30ng/ml	vitamin D >30ng/ml	p-value
HbA1c	8.3 $\pm$ 2.6	7.1 $\pm$ 1.5	7.45 $\pm$ 1	0.515

### The association between hypovitaminosis D and metabolic syndrome is not dependent on body fat mass

I. Barchetta<sup>1</sup>, D. Capoccia<sup>2</sup>, M.G. Baroni<sup>3</sup>, M. De Bernardinis<sup>1</sup>, C. Costantino<sup>1</sup>, F. Leonetti<sup>2</sup>, M.G. Cavallo<sup>1</sup>;

<sup>1</sup>Dept. Internal Medicine and Medical Specialties, Sapienza University of Rome, <sup>2</sup>Dept. of Medical Pathophysiology, Sapienza University of Rome, <sup>3</sup>Endocrinology and Metabolism, Department of Medical Sciences, University of Cagliari, Italy.

**Background and aims:** Metabolic syndrome (MS) and hypovitaminosis D represent two of the most diffuse conditions worldwide, reaching pandemic proportions in industrialized countries, and are both tightly associated with obesity. Aim of this study was to determine if an independent association exists between low 25(OH)vitamin D3 levels and MS in obese patients.

**Materials and methods:** For this purpose we recruited 107 consecutive obese subjects, 61 with MS (age (mean $\pm$ SD):  $45.3 \pm 13.3$ , BMI:  $43.1 \pm 8.3 \text{ kg/m}^2$  and 46 without MS (age:  $41.8 \pm 11.5$ ,  $p=\text{n.s.}$ , BMI:  $41.6 \pm 6.5 \text{ kg/m}^2$ ,  $p=\text{n.s.}$ ) comparable for sex, BMI, waist circumference and body fat mass, evaluated by bioimpedanzimetry. All participants underwent a complete workup including physical examination, blood testing and serum 25(OH)vitamin D3 measurement. Insulin resistance was estimated by HOMA-IR, ISI and QUICKI indexes.

**Results:** Serum 25(OH)vitamin D3 levels were significantly reduced in obese patients with MS compared with obese subjects without MS ( $14.9 \pm 6.2 \text{ ng/ml}$  vs  $18.9 \pm 8.2 \text{ ng/ml}$ ,  $p<0.007$ ). The multivariate regression analysis confirmed that low serum 25(OH)vitamin D3 levels were associated with the diagnosis of MS in obese patients independently from gender, age serum PTH and body fat mass. After stratifying the study population according to 25(OH)vitamin D3 levels, patients in the lowest vitamin D quartile showed a markedly increased prevalence of MS with an OR of 4.1 (CI 1.2–13.7,  $P=0.02$ ) compared to those in the highest quartile.

**Conclusion:** A powerful association exists between hypovitaminosis D and MS in obese patients independently from body fat mass and its clinical correlates. This indicates that the association between low serum 25(OH)vitamin D3 levels and MS is not merely induced by vitamin D deposition in fat tissue and reinforce the hypothesis that hypovitaminosis D represent a crucial independent determinant of MS.

## 875

**Effect of Ramadan fasting on diabetes control in type 2 diabetics**

H. Ibrahim, H. Ouertani, A. Dorai, A. Jaidane, C. Zouaoui, B. Zidi;  
Service of Endocrinology Diabetology, Military Hospital – Monfleury,  
Tunis, Tunisia.

**Background and aims:** To determine effects of the intervention of education and study of Ramadan fasting on the metabolic control diabetes.

**Materials and methods:** 100 diabetic patients were recruited two months before the start of Ramadan. Pre-Ramadan counseling, and education was given to all patients on diet, drug and acute complications of diabetes. People with complication fluctuating blood sugar and no self monitoring blood sugar were excluded from trial. Following parameters were checked before and one month of completing 30 days of Ramadan Fasting (age, sex, weight, treatment, FBS, Lipid profile, number of meals, physical activity, HbA<sub>1c</sub> and Hypoglycaemia episodes during Fasting). 87 were on OHA, 9 on insulin and 4 on combination therapy.

**Results:** 37 patients lost weight, 51 gained weight, no weight change was seen in 12. HbA<sub>1c</sub> decreased in 58, increased in 38, did not change in 4. Patients who took 3 meals as compared to 2 showed increase in FBS (126 mg/dl to 138), HbA<sub>1c</sub> (7,2 % to 7,8) and cholesterol (188 mg/dl to 210). While patients who had 2 meals showed improvement in HbA<sub>1c</sub> (7,6 % to 6,8), cholesterol (188 mg/dl to 176). Although compared to pre-Ramadan, the post Ramadan data showed increase in FBS (128 to 135 mg/dl) but avg. HbA<sub>1c</sub> reduced from 8,3% to 7,5%. Cholesterol from 188 to 178 mg /dl suggesting good effect of Ramadan fasting on HbA<sub>1c</sub> and lipid profile. During Ramadan month 13 episodes of hypoglycaemia but only 2 were severe enough to break the fast but no requiring hospital admission. 11 episodes were in OHA group only 2 in insulin taking patients.

**Conclusion:** Ramadan fasting in diabetics can be safe, but it needs more education in pre-Ramadan counselling of both patients and their family members especially in terms of diet and drug compliance.

## 876

**Hepatic fat content is related to the carbohydrate intake, in patients with non alcoholic fatty liver disease (NAFLD)**

V. Rigalleau, C. Gonzalez, J. Vergniol, J. Foucher, F. Chermak, S. Carlier,  
E. Maury, B. Cherifi, H. Gin, V. de Ledinghen;  
USN, Hopital Haut-Lévêque, Pessac, France.

**Background and aims:** NAFLD are now the first cause of hepatic diseases, and their first treatment is diet. According to studies by magnetic resonance, the drastic reduction of the carbohydrate intake (20-30 grams/day) during two weeks leads to a half-reduced hepatic fat content. Is hepatic steatosis related to the spontaneous carbohydrate intake in patients with NAFLD?

**Materials and methods:** We performed dietary records (BillNutIV software) in 24 patients with NAFLD, 3±2 months after their hepatic biopsy was performed, and before the deliverance of a dietary advice. Other causes of liver diseases (virus, drugs) were excluded, as were the subjects who declared an excessive alcohol consumption (>20g/d for women and 30g/d for men), and the subjects who had known diabetes, that might have led them to restrain their carbohydrate intake. The food quotient, indicator of the proportion of calories from carbohydrates, was calculated as: (1.00X % calories from carbohydrates/100) +(0.70X % calories from lipids/100) +(0.81 X % calories from proteins/100). The associations between diet variables and % steatosis on the hepatic biopsies were tested by regression analysis, and diet variables were compared according to the presence of fibrosis and inflammation on the biopsies.

**Results:** The subjects (15 men, 9 women, age 45±13 yrs, BMI 29.7±3.8, ALAT 72±53U, GGT 117±98U) displayed a large range of hepatic steatosis: 50.5%±25.5 [10-90], correlated to their energy intake (1993±597 kcal/d, r=0.41, p<0.05) and their food quotient (0.85±0.02, r=0.42, p<0.05), which remained significant with both variables by a multivariate regression analysis (r=0.51, p<0.05). For the 17/24 patients with a hepatic fibrosis, the energy intake was lower (Fibrosis:1863±503 vs others: 2382±733 kcal/d, p<0.05), and the history of previous overweight was more pronounced as reflected by a higher maximal BMI during their life (Fibrosis: 33.2±3.4 vs others: 27.4±4.0 kg/m<sup>2</sup>, p<0.05). For the 15/24 patients with hepatic inflammation on the biopsy, we did not detect any difference in the diet.

**Conclusion:** Hepatic steatosis is related to the energy and carbohydrate intakes in our patients who had a hepatic biopsy for NAFLD: the role of dietary carbohydrates is detectable in the range of usual carbohydrate intake (32% to 58% of calories were from carbohydrates in our patients). The carbohydrate proportion did not differ in the patients with hepatic fibrosis.

## 877

**Effects of the prudent diet versus low fat diet in cytokines profile in patients with diabetes and chronic hepatitis C**

E.D. Rusu<sup>1</sup>, M. Jinga<sup>2</sup>, G. Enache<sup>3</sup>, F. Rusu<sup>4</sup>, A. Dragomir<sup>5</sup>, I. Ancuta<sup>2</sup>,  
R. Dragut<sup>5</sup>, R. Nan<sup>5</sup>, I. Sima<sup>6</sup>, S. Ateia<sup>7</sup>, V. Stoica<sup>8</sup>, D. Cheta<sup>9</sup>, G. Radulian<sup>5</sup>;

<sup>1</sup>Nutritioiabetes, D, University of Medicine and Pharmacy, Bucharest,

<sup>2</sup>Gastroenterology, University of Medicine and Pharmacy, Bucharest,

<sup>3</sup>Diabetes, Emergency Hospital, Contanta, Romania, <sup>4</sup>Urology, Emergency Military Hospital Carol Davila, Bucharest, <sup>5</sup>Diabetes, University of Medicine and Pharmacy, Bucharest, <sup>6</sup>Diabetes, National Institute of Diabetes, Nutrition and Metabolic Diseases, Bucharest, <sup>7</sup>Diabetes, Medas Clinic, Bucharest,

<sup>8</sup>Gastroenterology, University of Medicine Carol Davila, Bucharest, Romania.

**Background and aims:** Chronic hepatitis C (CHC) is characterized by a chronic inflammatory status in the liver, with increased production of pro-inflammatory cytokines such as tumor necrosis factor alpha (TNF-α) and interleukin 6 (IL-6), which may enhance the IR. The aim of this study was to compare the prudent diet (PD) with a low-fat diet (LFD) in patients with CHC and diabetes. The purpose was to measure the impact of dietary changes on reduction of insulin resistance, and on improving the cytokines profile (adiponectin, leptin, TNF-α, IL-6, resistin).

**Materials and methods:** This multicenter, randomized controlled trial was conducted during September 2007 - December 2010. 120 participants were recruited from three hospitals from Bucharest, Romania. The inclusion criteria were: age over 35 years, diagnosis of chronic hepatitis C (CHC infection was defined by the presence of anti-HVC for a least 6 months and a positive

HCV-viremia) and diabetes. Following completion of baseline assessments, participants were randomized to the prudent diet (PD), or to the low fat diet (LFD) group, both with a lifestyle management program. We performed anthropometric measurements (weight, height, BMI (body mass index), waist circumference, waist to hip ratio (WHR) every month. The biochemical analyses, which included fasting serum lipids, glucose profile, liver profile, were performed at baseline, 6 and 12 months. The serum concentrations of adiponectin, leptin, resistin, TNF- $\alpha$ , IL-6 were measured by enzyme-linked immunosorbent assay (ELISA) at baseline and 12-months.

**Results:** After 6 and 12 months of intervention, both groups had a significant decrease in caloric consumption. At 6 months, weight loss was greater in the PD group ( $-5.02 \pm 3.43$  kg vs.  $-4.1 \pm 2.6$  kg;  $p=0.002$ ) compared to the LFD group. At 1-year, however, weight loss was similar in both groups ( $-3.9 \pm 3.3$  kg vs.  $-3.1 \pm 2.6$  kg;  $p=0.139$ ). HOMA-IR was normalized in 10.3% of PD patients ( $n=3$ ) and 4% ( $n=1$ ) of patients in LFD and improved to 46.2% ( $n=6$ ) of PD and 15.4% ( $n=2$ ) of the patients in the LFD. With both diet leptin, TNF- $\alpha$ , IL-6 and resistin decreased and adiponectin increased with significant differences; also there were significant improvements in AST/ALT ratio, AST/Platelets ratio and Forns index.

**Conclusion:** Patients with hepatitis C following a lifestyle intervention for 1-year had significant improvements in overweight or obesity, fasting glucose, fasting insulin, HOMA-IR, lipid, hepatic and cytokine profile with both diets. Supported by: PNCDI 2 program DIADIPOHEP 41-008/2007

### Effects of dietary polyphenols and/or n-3 fatty acids on postprandial lipaemia in people at high cardiovascular risk: the Etherpaths project

G. Annuzzi<sup>1</sup>, L. Bozzetto<sup>1</sup>, G. Costabile<sup>1</sup>, G. Della Corte<sup>1</sup>, G. Anniballi<sup>1</sup>, M. Vitale<sup>1</sup>, S. Cocozza<sup>1</sup>, R. Giacco<sup>2</sup>, C. Vetrani<sup>1</sup>, A. Rivieccio<sup>1</sup>, L. Patti<sup>1</sup>, G. Della Pepa<sup>1</sup>, G. Riccardi<sup>1</sup>, A.A. Rivellese<sup>1</sup>

<sup>1</sup>Department of Clinical and Experimental Medicine, Federico II University,

<sup>2</sup>National Council Research, Naples, Italy.

**Background and aims:** Postprandial lipaemia is an independent risk factor for cardiovascular disease. Among the dietary elements potentially able to reduce the cardiovascular risk much interest is currently placed on polyphenols and n-3 fatty acids. Their effects on postprandial lipid metabolism, especially when combined, are not known. Therefore, the aims of this study were to evaluate the effects of diets rich in polyphenols and/or n-3 fatty acids and their possible interaction on triglyceride-rich lipoprotein levels after a fat test meal in people at high cardiovascular risk.

**Materials and methods:** Seventy-four individuals, age 35–70 years, with high BMI ( $27\text{--}35$  kg/m<sup>2</sup>) and waist circumference (men  $>102$  cm, women  $>88$  cm), and one more component of the metabolic syndrome, were randomized to one of the following diets for 8 weeks: (A) poor in n-3 fatty acids and polyphenols, (B) rich in n-3 fatty acids, (C) rich in polyphenols, (D) rich in n-3 fatty acids and polyphenols. The diets were isocaloric and similar for content of MUFA, saturated fat, cholesterol, carbohydrates, fibre, proteins, and vitamins. Before and after the 8-week intervention, lipid concentrations in plasma and lipoprotein subfractions separated by density gradient ultracentrifugation were determined, both at fasting and over 6 hours after a high fat meal of the same composition as the diet assigned.

**Results:** The results refer to the 63 participants who have already completed the study, 19 for diet A, 14 for diet B, 15 for diet C, and 15 for diet D. Adherence to diet was optimal in all groups. The postprandial incremental areas under the curve (iAUC) of cholesterol and triglycerides in chylomicrons were reduced with diets B, C, and D with respect to the control diet A, significantly for cholesterol between diet A and B ( $p<0.05$ , ANOVA post-hoc analysis). The iAUC of triglycerides in VLDL1 was significantly reduced with diet D compared to the control diet ( $p<0.05$ ).

**Conclusion:** These preliminary results indicate that diets rich in n-3 fatty acids and/or polyphenols positively influence the postprandial response of triglyceride-rich lipoproteins, and therefore may have favourable effects on cardiovascular risk.

### Determination of glycaemic index of corn flakes, white bread & ham, yogurt, muesli cake, fruit muesli and multigrain cake at different times of day using continuous glucose monitor

R. Chlup<sup>1</sup>, J. Zapletalova<sup>2</sup>, P. Kudlova<sup>3</sup>, V. Milata<sup>4</sup>, P. Seckar<sup>1</sup>, K. Peterson<sup>1</sup>, J. Matouskova<sup>1</sup>, J. Tomcalova<sup>1</sup>, J. Bartek<sup>5</sup>

<sup>1</sup>Dept. of Physiology, Faculty of Medicine, Palacký University Olomouc, Czech Republic, <sup>2</sup>Dept. of Biophysics, Faculty of Medicine, Palacký University Olomouc, Czech Republic, <sup>3</sup>Faculty of Humanities, Bata University, Zlin, Czech Republic, <sup>4</sup>St. Elizabeth University College of Health and Social Work Bratislava, Slovakia, <sup>5</sup>Faculty of Medicine, Palacký University Olomouc, Czech Republic.

**Background and aims:** Glycaemic index of foods (GI) is routinely determined according to the ISO 26642:2010 in at least 10 healthy persons after an overnight fast using fingerprick or venous blood analysed in the laboratory. The objective of this prospective open label study was (1) to assess the differences of GI for 6 popular foods determined by means of continuous glucose monitoring system (CGMS) with transcutaneous sensor, transmitter and monitor at breakfast, lunch, snack and two dinner times and (2) to assess the input of CGMS and related software for GI determination.

**Materials and methods:** In November 2011, 19 healthy volunteers aged 18–44 y, BMI  $23.5 \pm 1.1$  kg/m<sup>2</sup> (mean  $\pm$  SE), CGMS-trained, completed the study. Each subject consumed 6 different foods and glucose standard (50 g), each of them on 5 separate occasions at 5 different times of day according to a defined meal plan over a 9-day period. There were no tests on day 4 which was used to recharge the transmitter; tested persons were allowed to consume foods according to their free choice. Daily energy intake varied mostly between 7 000 and 8 000 kJ (250 g of sacharides, 80 g of proteins, up to 50 g of fat). The sensor was calibrated 3 times a day using glucometer. Any tests that did not fulfill the evaluation criteria (at least 210 min fast before and after meal start, exact portion of food consumed within 30 min, sensor failures exceeding 25 min) were not processed. GIs exceeding 3 times the interval between 25 and 75 percentil were excluded, such as 509/665 tests (77%, namely 69–85% of tests with each individual food) were analyzed using software SPSS v. 15.0. Data were processed using the software Carelink and DegifXL5.

**Results:** In all individual foods the Shapiro-Wilk test showed a non-normal distribution of GI. Therefore the values are presented as medians and percentil 25 and 75. The paired Wilcoxon signed-rank test with Bonferroni correction revealed no significant differences between respective GIs determined at breakfast, lunch, snack and dinner times. Median of individual means is the final GI (Table 1).

**Conclusion:** Tests performed at different times of day using CGMS appear to be a promising method for GI determination. Presenting the results as medians and percentiles brings more information on distribution of GI values. Despite of deviations from ISO 26642 this approach offers a better insight into postprandial evolution of glycaemia over 24 h.

Table 1: GI of foods [%] at different times of day (median, percentil 25, 75); median of means

Meal	Breakfast	Lunch	Snack	Dinner1	Dinner2	Means
Time	7.00	11.00	15.00	19.00	23.00	
Dark choco	33	46	101	80	40	60
cornies 85 g	18-98	31-94	74-124	26-139	16-96	51-91

**Does treatment with n-3 polyunsaturated fatty acids influence vitamin D status in severely obese non-diabetic subjects?**T.M. Stulnig<sup>1,2</sup>, L. Leitner<sup>1,2</sup>, R. Marculescu<sup>3</sup>, M. Zeyda<sup>1,2</sup>, B.K. Itariu<sup>1,2</sup>;<sup>1</sup>Clinical Division of Endocrinology and Metabolism, Medical University of Vienna, <sup>2</sup>Christian Doppler Laboratory for Cardio-Metabolic Immunotherapy, <sup>3</sup>Department of Laboratory Medicine, Medical University of Vienna, Austria.

**Background and aims:** Hypovitaminosis D is frequent among obese individuals. Recently, it was shown that the vitamin D status of patients receiving vitamin D3 supplements correlated negatively with the amount of total ingested polyunsaturated fatty acids (PUFA). n-3 PUFA and vitamin D have immunomodulatory effects which could help prevent obesity-associated complications, such as cardiovascular disease. Thus, we aimed to investigate whether treatment with long chain n-3 PUFA negatively affects vitamin D status in obese patients.

**Materials and methods:** In a randomized, controlled trial we treated 55 severely obese (BMI ≥ 40 kg/m<sup>2</sup>) non-diabetic patients with either 3,3 g/d n-3 PUFA (EPA/DHA) or the same amount of butter fat as control for 8 weeks. At baseline and end of treatment we determined plasma fatty acid profiles, circulating inflammatory marker and serum 25-hydroxyvitamin D (25(OH)D) concentrations. Statistical analysis was performed using RM-ANOVA and Spearman's rank correlation.

**Results:** At baseline, 44/55 patients were vitamin D deficient (25(OH)D ≤ 50 nmol/l). The serum 25(OH)D concentration correlated positively with plasma EPA content ( $\rho = 0,30$ ,  $P = 0,03$ ) and negatively with both IL-6 and hsCRP serum concentration ( $\rho = -0,31$ ,  $P = 0,02$  and  $\rho = -0,29$ ,  $P = 0,03$ , respectively). Overall, treatment with n-3 PUFA did not significantly affect vitamin D status compared to control ( $P = 0,57$ ). However, n-3 PUFA treatment during summer months significantly increased serum 25(OH)D concentrations ( $P = 0,002$ ). Median serum triglyceride and IL-6 concentrations were decreased by 15,9% and 24,8% in the n-3 PUFA compared to control group, respectively, but correlations of 25(OH)D with EPA and inflammatory markers were no longer detectable at the end of n-3 PUFA treatment.

**Conclusion:** Vitamin D status of severely obese patients does not deteriorate by 8 week n-3 PUFA treatment as has been suggested by epidemiological data. Potential synergistic effects of n-3 PUFA and vitamin D on obesity-associated comorbidities remain to be elucidated.

**Animal protein intake during puberty is related to the IGF-axis and insulin sensitivity in young adulthood**A.E. Buyken<sup>1</sup>, T. Remer<sup>2</sup>, K.E. Assmann<sup>2</sup>, D. Krupp<sup>2</sup>, G. Cheng<sup>2,3</sup>, S. Wudy<sup>3,4</sup>, A.L.B. Günther<sup>4</sup>, G. Joslowski<sup>2</sup>;<sup>1</sup>Department of Nutritional Epidemiology - DONALD, Rheinische-Friedrich-Wilhelms-University Bonn, <sup>2</sup>Department of Nutritional Epidemiology - DONALD, Rheinische-Friedrich-Wilhelms-University Bonn, <sup>3</sup>Center of Child and Adolescent Medicine, Laboratory for Translational Hormone Analytics in Paediatric Endocrinology, Gießen, <sup>4</sup>Department of Nutritional, Food, and Consumer Sciences, Fulda University of Applied Sciences, Germany.

**Background and aims:** Evidence from observational studies suggests that higher intakes of animal protein may predispose to some types of cancer and type 2 diabetes. This study addressed the hypothesis that such relations may already emerge during adolescence, analyzing animal and vegetable protein intakes during puberty for prospective associations with the IGF-axis and insulin sensitivity in young adulthood.

**Materials and methods:** Multivariable regression analysis was performed on data from 213 (118 female and 95 male) DONALD participants with at least two plausible 3-day weighed dietary records during puberty (girls: 9-14 years, boys: 10-15 years) and one blood sample in young adulthood (18-35 years). Mean levels of IGF-1, IGFBP-3 (n=213) as well as IGFBP-1, IGFBP-2, and HOMA-IR index (n=201) were compared between tertiles of habitual pubertal animal and vegetable protein intake.

**Results:** Among women, a habitually higher animal protein intake during puberty was independently associated with higher levels of IGF-1 (ptrend=0.009) and IGFBP-3 (ptrend=0.04), lower IGFBP-2 (ptrend=0.1),

and higher HOMA-IR values (ptrend=0.048), but not with IGFBP-1 (ptrend=0.5) in young adulthood. IGF-1 values in energy-adjusted tertiles of animal protein were 195 (95% CI 166, 227), 244 (211, 279) and 229 (197, 263) ng/ml, adjusted for age, blood sample, early life, socioeconomic and nutritional factors. Mean adjusted HOMA-IR values were 2.2 (1.9, 2.5), 2.7 (2.4, 3.1) and 2.7 (2.4, 3.1). Additional consideration of baseline fat mass attenuated the relation to HOMA-IR (ptrend=0.099), but not that to IGF-1 (ptrend=0.005). No prospective associations were observed for intakes of vegetable protein (ptrend>0.4). Protein intakes were not related to the IGF-axis or HOMA-IR among men.

**Conclusion:** Our data suggest that, among women, a habitually higher animal protein intake during puberty may precipitate an up-regulation of the IGF-axis and a modest adaptive decrease in insulin sensitivity, which are both still discernible in young adulthood.

**Prevalence of gestational diabetes by WHO and IADPSG criteria in women with four major dietary patterns: The STORK Groruddalen study**C. Sommer<sup>1</sup>, K. Mørkrid<sup>1,2</sup>, A. Mosdøl<sup>3</sup>, L. Sletner<sup>4,2</sup>, A.K. Jenum<sup>5</sup>, K.I. Birkeland<sup>1,2</sup>;<sup>1</sup>Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo University Hospital, Aker, <sup>2</sup>Institute of Clinical Medicine, University of Oslo, <sup>3</sup>Institute of Health, Nutrition and Management, Oslo and Akershus University College of Applied Sciences, <sup>4</sup>Norwegian Resource Centre for Women's Health, Oslo University Hospital, Rikshospitalet, <sup>5</sup>Institute of Health and Society, University of Oslo, Norway.

**Background and aims:** Gestational Diabetes Mellitus (GDM) affects short and long term health of both mother and offspring. Diet is thought to be an important factor affecting GDM risk and prevention. The aim was to explore how dietary patterns were associated with prevalence of GDM diagnosed by WHO and the The International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria, and to assess the relation with ethnicity.

**Materials and methods:** STORK Groruddalen is a population-based prospective cohort study of 823 (74% of the invited, 59% of non-Western origin) healthy pregnant women and their offspring attending three primary antenatal clinics in Eastern Oslo. The study population comprised 757 pregnant women who completed an interview administered food frequency questionnaire in 28 weeks of gestation. A hierarchical cluster analysis using squared euclidian distance was conducted to derive dietary patterns. The stability of the clusters was examined through split half replication. The dietary patterns were examined for association with GDM by the two criteria and ethnicity. All statistical analyses were performed using IBM SPSS Statistics 19.

**Results:** Four robust clusters were identified. Women born in Norway or other western countries were mainly associated with cluster 4 (60.5%), while women with other origin were rather evenly assigned into all four clusters. Cluster 1 and 2 had the highest prevalence of GDM (17.2 and 16.4 %), while cluster 3 and 4 had the lowest prevalence of GDM (9.9 and 10.1 %) with the WHO criteria. With the IADPSG criteria, clusters 1-3 had a similar prevalence of GDM (35.2-36.7 %) whereas cluster 4 had a significant lower prevalence (23.7 %,  $P = 0.008$ ). Except from for cluster 3, the prevalence trend were quite similar across the two criteria. A non-significant trend towards lower prevalence of GDM by IADPSG criteria in cluster 4 still was present when adjusting for ethnic background ( $p_{Western} = 0.493$ ,  $p_{Non-Western} = 0.671$ ), but the power to detect that was limited due to small numbers.

**Conclusion:** These results may indicate that dietary patterns similar to cluster 3 - high in beverages with sugar, polished rice and regular pasta, and low in fruit, vegetables, fish and milk - is associated with GDM with the IADPSG criteria, but not hyperglycemia severe enough to be identified as GDM with the WHO criteria. A diet similar to cluster 4 - high in whole grain/unpolished products, fruit and vegetables and low fat milk - may be more beneficial with respect to reduce the prevalence of GDM and should be tested in randomized studies.

**Table 1.** Prevalence of GDM by WHO and IADPSG criteria by ethnic origin within the dietary patterns

Ethnic origin	Prevalence of GDM, n (%)	Cluster 1 (n=125)	Cluster 2 (n=199)	Cluster 3 (n=183)	Cluster 4 (n=250)	p*
Western	WHO criteria	0 (0)	8 (15.1)	6 (10.0)	19 (10.2)	0.524
	IADPSG criteria	2 (22.2)	15 (28.3)	18 (30.0)	40 (21.4)	0.493
Non Western	WHO criteria	21 (18.6)	24 (16.9)	12 (9.9)	6 (9.8)	0.150
	IADPSG criteria	43 (37.4)	56 (39.7)	46 (37.7)	19 (30.6)	0.671
All	WHO criteria	21 (17.2)	32 (16.4)	18 (9.9)	25 (10.1)	0.062
	IADPSG criteria	45 (36.3)	73 (36.7)	64 (35.2)	59 (23.7)	0.008

### Fatty liver and insulin resistance: time course appearance of the changes induced by a fructose rich diet

L.M. Massa, C. Blaiotta, M.C. Castro, J.J. Gagliardino, F. Francini;  
CENEXA Center of Experimental and Applied Endocrinology, National University of La Plata, Argentina.

**Background and aims:** We have previously shown that administration of fructose to normal rats during 3 weeks induced insulin resistance, impaired glucose tolerance, fatty liver and hepatic carbohydrate metabolism abnormalities. The aim of this study was to evaluate the time-course of development of these alterations triggered by a fructose rich diet (FRD).

**Materials and methods:** For this purpose we fed normal male Wistar rats for 7, 14 and 21 days with a) a standard commercial diet (C) and b) a C diet plus 10% fructose in the drinking water (DRF). At each time we measured glycemia (G), triglyceridemia (TG) and insulinemia (I). HOMA-IR, HOMA- $\beta$  and Index for hepatic sensitivity to insulin (IHIS) ratios were calculated. In liver we measured a) protein carbonyl groups and reduced glutathione (GSH) as oxidative stress markers (OSM), b) liver glycogen and triglyceride content, c) glucokinase (GK), glucose-6-phosphatase (G-6-Pase) and glucose-6-phosphate dehydrogenase (G-6-P DH) activities and d) SREBP-1c, fatty acid synthase (FAS), glycerol-3-phosphate acyltransferase (GPAT), G-6-Pase and G-6-P DH gene expression.

#### Results:

	C1	FRD1	C2	FRD2	C3	FRD3

G6Pase (latency %)	8 $\pm$ 2	13 $\pm$ 3	8 $\pm$ 1	18 $\pm$ 2*	7 $\pm$ 1	15 $\pm$ 1*
Glycogen ( $\mu$ g/mg t)	7,0 $\pm$ 0,4	7,4 $\pm$ 0,3	6,8 $\pm$ 0,4	8,2 $\pm$ 0,2*	8,4 $\pm$ 0,3	10,8 $\pm$ 0,4*
Liver TG ( $\mu$ g/100 mg t)	304 $\pm$ 13	470 $\pm$ 59*	277 $\pm$ 30	376 $\pm$ 30	301 $\pm$ 25	469 $\pm$ 17*

(\*p&lt;0.05 vs.C)

Enhanced expression of all genes was recorded after one week. Carbonyl content was increased and GSH was reduced at two weeks treatment.

**Conclusion:** Increased serum and liver content of TG were the earliest changes induced by fructose administration while OSM and other liver dysfunctions appeared on the second week while enhanced HOMA  $\beta$  and hyperinsulinemia ( $\beta$  cell reaction) were the latest change recorded suggesting that would be the consequence of metabolic and OS occurred in liver and probably adipose tissue as well.

### Comparison of glycaemia variability in patients with type 2 diabetes given mitiglinide or sitagliptin, using continuous glucose monitoring: a pilot study

K. Ando, R. Nishimura, D. Tsujino, C. Seo, A. Morimoto, M. Sakamoto, K. Utsunomiya;  
Jikei University School of Medicine, Tokyo, Japan.

**Background and aims:** This study aimed to compare glucose variability in patients with type 2 diabetes given Mitiglinide (M) or Sitagliptin (S), using continuous glucose monitoring (CGM).

**Materials and methods:** The present study included nine patients with type 2 diabetes, aged from 20 to 79 years of age. The patients were randomly assigned to receive either M 30 mg/day or S 50 mg/day. After two months of treatment with M or S, they were hospitalised for four days, for evaluation by CGM. When the patients were discharged from the hospital, the drugs they received were switched so that they then took the one that they had not previously had. Again, after two months of treatment, they were hospitalised for four days for evaluation by CGM. The patients were given the same meals on days two and three of both their hospitalisations, and the CGM data on day three were used. Variables that were compared by using t-test included 1) the mean glucose levels, 2) the standard deviations (SD) of mean glucose levels, 3) the mean amplitude of glycaemic excursions (MAGE), 4) the range of glucose increase from pre-prandial to post-prandial peak glucose levels, 5) the time from pre-prandial to post-prandial peak glucose levels, and 6) the area under the curve (AUC) that measured over 140 mg/dL three hours after each meal. Statistical analyses were performed using SPSS 17.0. This study was approved by the Institutional Review Board of our university.

**Results:** The patients were  $59.8 \pm 10.4$  (mean  $\pm$  SD) years old, had HbA1c value  $7.29 \pm 0.85\%$  and BMI of  $24.7 \pm 3.20$  kg/m<sup>2</sup>. Their mean glucose levels tended to be lower with M than with S (mean glucose levels, M  $147.4 \pm 26.5$  vs. S  $158.6 \pm 34.2$  mg/dL; SD, M  $24.7 \pm 11.5$  vs. S  $30.1 \pm 14.4$ ), while MAGE were found to be similar with M and S ( $77.3 \pm 34.8$  and  $84.7 \pm 40.4$ , respectively). The range of the glucose increase from pre-prandial to post-prandial peak glucose levels was also similar for M and S. The time to the post-prandial peak glucose levels after breakfast, lunch, and dinner, with M and S, was  $102.2 \pm 33.6$  and  $108.9 \pm 37.1$  minutes,  $77.8 \pm 31.6$  and  $110.0 \pm 27.6$  minutes, and  $78.3 \pm 26.5$  and  $92.2 \pm 23.7$  minutes, respectively. This shows that the time from the pre-prandial to the post-prandial peak glucose levels was significantly ( $P = 0.022$ ) shorter after lunch, with M than with S, but was similar with M or S after both breakfast and dinner. The AUC measuring over 140 mg/dL three hours after breakfast tended to be lower with M than with S ( $4547.2 \pm 3682.0$  and  $8005.6 \pm 6815.2$ , respectively,  $P = 0.059$ ) but, at three hours after lunch or dinner, there was no significant difference between M or S.

**Conclusion:** An in-depth CGM-based study of glucose variability with M and S showed that there was no significant difference between M and S with respect to the SD, MAGE, and the range of glucose increase from the pre-prandial to the post-prandial peak glucose levels. The time from the pre-prandial to the post-prandial peak glucose levels was shown to be significantly shorter with M than with S after lunch, and the mean glucose levels and the AUC above 140 mg/dL three hours after breakfast tended to be lower with M than with S.

### Dietary intake and serum level of n-3 polyunsaturated fatty acids as predictors of DPP-4 inhibitor efficacy in patients with type 2 diabetes

M. Iwasaki<sup>1</sup>, D. Yabe<sup>2</sup>, F. Hoshian<sup>1</sup>, T. Tsuji<sup>1</sup>, N. Hirose<sup>1</sup>, T. Matsumoto<sup>1</sup>, N. Kitatani<sup>1</sup>, K. Sugawara<sup>2</sup>, R. Usui<sup>2</sup>, H. Kuwata<sup>2</sup>, S. Fujiwara<sup>2</sup>, K. Watanabe<sup>2</sup>, T. Hyo<sup>2</sup>, T. Kurose<sup>2,1</sup>, Y. Seino<sup>2</sup>;

<sup>1</sup>Division of Metabolism and Clinical Nutrition, <sup>2</sup>Division of Diabetes, Clinical Nutrition and Endocrinology, Kansai Electric Power Hospital, Osaka, Japan.

**Background and aims:** Dipeptidyl peptidase-4 (DPP-4) inhibitors improve glycemic control in patients with type 2 diabetes by preventing degradation of two incretin hormones, glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP), which are secreted from the intestine upon ingestion of various nutrients. Recent studies have shown associations of DPP-4 inhibitor efficacy with age and fasting plasma glucose levels as well as with baseline HbA1c and BMI, but clinical parameters for predicting

the outcome of DPP-4 inhibitor treatment are largely unknown. This study was initiated to identify clinical and dietary parameters for predicting efficacy of DPP-4 inhibitors.

**Materials and methods:** A total of 72 untreated patients with type 2 diabetes who received monotherapy of a DPP-4 inhibitor (sitagliptin, alogliptin or vildagliptin) for 4 months were examined for changes in HbA1c and BMI and self-administered 3-day food records and serum levels of fatty acids. Multiple linear regression analyses were performed to identify parameters associated with HbA1c reduction and simple regression analyses were carried out to evaluate their contributions.

**Results:** DPP-4 inhibitors, as in previous reports, significantly reduced HbA1c levels but not body weight [Before  $7.2 \pm 0.7\%$ ; 4 months after initiation  $6.7 \pm 0.6\%$  (paired t-test,  $p < 0.01$  versus before)]. Multiple regression analysis of HbA1c reduction taking into account sex, age, duration of diabetes, BMI, baseline HbA1c and estimated intake of various food categories in 3-day food records, revealed that HbA1c reduction was well correlated with baseline HbA1c but was not correlated with BMI. HbA1c reduction also showed a significant association with estimated intake of fish in the food records. The beneficial effects of fish on human health have been partly attributed to n-3 polyunsaturated fatty acids (PUFA) such as EPA and DHA. We therefore investigated the association of HbA1c reduction with estimated intake of PUFA. HbA1c reduction was significantly correlated with estimated intake of EPA and DHA along with baseline HbA1c. Since serum EPA and DHA levels might serve as markers for intake of corresponding fatty acids, we analyzed the associations of HbA1c reduction with serum EPA and DHA levels. Serum levels of EPA and DHA, but not those of n-6 PUFA arachidonic acid, were well correlated with HbA1c reduction.

**Conclusion:** HbA1c reduction by DPP-4 inhibitors is significantly associated with estimated dietary intake of fish and n-3 PUFA and also with serum levels of EPA and DHA. Thus, the clinical efficacy of DPP-4 inhibitors can be predicted by serum EPA and DHA levels.

#### Vitamin D supplementation as an adjuvant therapy for Saudi Arabian patients with type 2 diabetes mellitus: an 18-month interventional study

A.-D. Nasser, Biomarkers Research Program and Prince Mutaib Chair for Biomarkers of Osteoporosis;  
King Saud University, Riyadh, Saudi Arabia.

**Background and aims:** Vitamin D deficiency has been shown to impair human insulin action, suggesting a role in the pathogenesis of Type 2 diabetes mellitus (T2DM). Despite the level of sunshine in Saudi the population has significant vitamin D deficiency based on our previous studies. In this prospective interventional study we investigated the effect of vitamin D (Vit D) supplementation in the metabolic and glycemic profiles of the Saudi T2DM subjects pre and post supplementation to improve known Vit D deficiency compounded in metabolic states such as T2DM.

**Materials and methods:** T2DM Saudi subjects (men: age:  $56.6 \pm 8.7$  yr, BMI,  $n=34$ ;  $29.1 \pm 3.3$  kg/m<sup>2</sup>; females: Age:  $51.2 \pm 10.6$  yr, BMI  $34.3 \pm 4.9$  kg/m<sup>2</sup>;  $n=58$ ) were recruited and given 2000IU vitamin D3 daily for 18 months. Anthropometrics and biochemical data was collected (0, 6, 12, 18 months) to monitor serum 25 hydroxyvitamin D [25(OH) D (nmol/L)] using a commercial ELISA, as well as glycemic and lipid profiles.

**Results:** In all T2DM subjects there was a significant increase in mean circulating 25(OH)D levels from baseline ( $32.2 \pm 1.5$  nmol/L) to 18 months ( $54.7 \pm 1.5$  nmol/L;  $p < 0.001$ ) as well as with serum calcium [Baseline =  $2.3 \pm 0.23$  mmol/L versus 18 months =  $2.6 \pm 0.1$  mmol/L;  $p = 0.003$ ]. A significant increase in HDL-cholesterol was noted only in females ( $p < 0.001$ ), as well as a significant decrease in LDL- calcium [Baseline =  $4.4 \pm 0.8$  mmol/L versus 18 months =  $3.6 \pm 0.8$  mmol/L] and total cholesterol calcium [Baseline =  $5.4 \pm 0.2$  mmol/L versus 18 months =  $4.9 \pm 0.3$  mmol/L] ( $p < 0.001$  and  $p < 0.001$  respectively). In all subjects, glycemic parameters (glucose, insulin, HOMA-IR), blood pressure and BMI were comparable.

**Conclusion:** In summary, the results highlight that despite oral Vitamin D supplementation (2000IU/day) in Saudi subjects with T2DM; circulating 25(OH)D levels still remain deficient by 22% below normal 18 months post treatment. However, supplementation appeared to significantly improve lipid profile with a change in HDL/LDL ratio which was more pronounced in T2DM females, offering other benefits for health. This study suggests that T2DM Saudi subjects require a higher Vitamin D supplementation (3000IU/day) as a clinical recommendation to achieve normal vitamin D status.

#### The novel oral drug subetta exerts anti-diabetic effect in the diabetic GK/Par rat

E.A. Gorbunov<sup>1</sup>, S.A. Tarasov<sup>1</sup>, O.I. Epstein<sup>1</sup>, D. Bailbe<sup>2</sup>, E. Philippe<sup>2</sup>, B. Portha<sup>2</sup>;

<sup>1</sup>OOO NPF Materia Medica Holding, Moscow, Russian Federation,

<sup>2</sup>B2PE-BFA Unit, University Paris-Diderot, Paris, France.

**Background and aims:** The search for new targets and the development of novel anti-diabetic drugs ensuring high efficacy on a background of minimal side effects are still pressing issues. Subetta, containing ultra diluted solution of antibodies to C- terminal fragment of insulin receptor and antibodies to endothelial NO synthase, could be one of such drugs. Preliminary in-house studies in rats with streptozotocin-induced diabetes suggested that Subetta reduced hyperglycemia to an extent similar to Rosiglitazone. Toxicological studies revealed a high drug safety. The aim of the present pre-clinical study was to evaluate Subetta antidiabetic efficacy in a rat model of non-obese type 2 diabetes.

**Materials and methods:** The study was conducted in adult male Goto Kaki-zaki rats from the Paris colony (GK/Par) (age 10-12 weeks). The rats were randomized into 3 groups ( $n=12$  each): group 1 - Subetta (5 ml/kg/daily), group 2 - Rosiglitazone (5 mg/kg/daily; reference drug), group 3 (control) - vehicle (5 ml water/kg/daily). The drugs and control were administered by gavage for 28 days once daily (9:00). Twice a week (non fed state) prior to drug administration (9:00), the animals were weighted and water, food intake

and basal plasma glucose level were evaluated. One day prior to first drug administration (D0), 3 hours after the first drug administration (12:00) (D1), and 3 hours after the last drug administration (12:00) (D28), oral glucose tolerance tests (OGTT) (2 g glucose/kg rat; unanesthetized state) were sequentially performed on each animal. Plasma glucose and insulin changes were determined from blood samples collected before and 5, 10, 15, 30, 60 and 120 min after glucose administration. Glucose AUC and insulin AUC were calculated to quantify glucose tolerance and glucose-induced insulin secretion. Non-parametric Mann-Whitney U and Wilcoxon tests were used for statistical analysis of the results.

**Results:** At D28, basal plasma glucose levels were significantly decreased in Subetta and Rosiglitazone groups as compared to control group:  $147 \pm 4$  mg/dL ( $p < 0.01$ ) and  $145 \pm 4$  mg/dL ( $p < 0.01$ ) and  $165 \pm 4$  mg/dL, respectively. The OGTT data showed that Subetta administration (similar to Rosiglitazone) prevented significantly ( $p < 0.01$ ) the age-related (from D0 to D28) spontaneous deterioration of glucose tolerance as seen in the control group: from D0 to D28, glucoseAUC increased by 47% in the control group, and only by 17% and 27% in the Subetta and Rosiglitazone groups respectively. Subetta did not significantly modified the glucose-induced insulin secretion which remained as low on D28 as it was on D0. Subetta and Rosiglitazone did not affect body weight, despite a slight reduction in daily food intake as compared to control group: respectively,  $66 \pm 1$  g food/kg rat ( $p < 0.05$ ) and  $62 \pm 1$  g food/kg rat ( $p < 0.01$ ) and  $71 \pm 1$  g food/kg rat.

**Conclusion:** Chronic administration of the novel oral drug Subetta improves glucose control in the GK/Par rat model of type2 diabetes, to an extent similar to that of Rosiglitazone. This cannot be explained by insulin secretion restoration and we hypothesize that Subetta mostly acts via an insulin sensitizing effect upon target tissues.

## 888

### Testosterone replacement therapy in middle-aged to elderly hypogonadal men leads to continuous weight loss and reduction in waist circumference over five years

F. Saad<sup>1,2</sup>, A. Haider<sup>3</sup>,

<sup>1</sup>Scientific Affairs Men's Healthcare, Bayer Pharma AG, Berlin, Germany,

<sup>2</sup>Research Department, Gulf Medical University School of Medicine, Ajman, United Arab Emirates, <sup>3</sup>Private Urology Practice, Bremerhaven, Germany.

**Background and aims:** Obesity in men is frequently associated with testosterone deficiency. Adipose tissue is an active endocrine organ producing substances (e.g., estrogens, cortisol, leptin, inflammatory cytokines) which suppress the production of endogenous testosterone at the hypothalamic-pituitary level and at the testicular level. This study aimed at investigating the effects of testosterone replacement in hypogonadal men on parameters of obesity.

**Materials and methods:** Open-label, single-center, cumulative, prospective registry study of 255 men (mean age  $60.6 \pm 8.0$  years), with testosterone levels  $\leq 3.5$  ng/mL (12 nmol/L) receiving parenteral testosterone undecanoate 1000 mg at baseline, after 6 weeks and thereafter at 12-week intervals.

**Results:** After a maximum treatment duration of five years, the following changes occurred: testosterone increased from  $2.87 \pm 0.4$  to  $5.26 \pm 0.44$  ng/mL. Body weight (kg) decreased from  $106.22 \pm 16.93$  (minimum: 70, maximum: 139) to  $90.07 \pm 9.51$  (min 74.00, max 115). The statistical significance was  $p < 0.0001$  vs baseline and vs the previous year over 5 years indicating a continuous weight reduction. Waist circumference (cm) declined from  $107.24 \pm 9.14$  (min 86, max 129) to  $98.46 \pm 7.39$  (min 84, max 117) ( $p < 0.0001$  vs baseline and vs the previous year over 5 years). Body mass index (BMI, m/kg<sup>2</sup>) declined from  $33.93 \pm 5.54$  (min 21.91, max 46.51) to  $29.17 \pm 3.09$  (min 22.7; max 36.71) ( $p < 0.0001$  vs baseline and vs the previous year over 5 years). The mean per cent weight loss after 1 year was  $4.12 \pm 3.48\%$ , after 2 years  $7.47 \pm 5.01\%$ , after 3 years  $9.01 \pm 6.5\%$ , after 4 years  $11.26 \pm 6.76\%$  and after 5 years  $13.21 \pm 7.24\%$ . At baseline, 96% of men had a waist circumference of  $\geq 94$  cm. This proportion decreased to 71% after 5 years.

**Conclusion:** The normalization of testosterone in hypogonadal men resulted in progressive loss of weight, waist circumference and BMI over the full 5 years of the study.

### TR-beta selective thyromimetics (KB-141) stimulates the proliferation of insulin secreting beta cells

T. Kim<sup>1,2</sup>, J. Lee<sup>1</sup>, H. Jung<sup>1</sup>, N. Han<sup>1</sup>, S. Kim<sup>1</sup>, E. Lee<sup>1</sup>, T. Kim<sup>1</sup>, M. Kwon<sup>1</sup>, S. Lee<sup>1</sup>, M. Kim<sup>1,2</sup>, M. Park<sup>3</sup>, B. Rhee<sup>1,2</sup>, G. Grover<sup>4</sup>, J. Park<sup>1</sup>;

<sup>1</sup>Division of Endocrinology and Metabolism, Department of Internal Medicine, Pusan Paik Hospital, Inje University, Busan, Republic of Korea,

<sup>2</sup>Paik Institute for Clinical Research, Busan, Republic of Korea, <sup>3</sup>Department of Internal Medicine, Dong-A University, Busan, Republic of Korea,

<sup>4</sup>Department of Pharmacology, Eurofins-Drug Safety Laboratories, Dayton, USA.

**Background and aims:** Thyroid hormone (T3) influences a variety of physiological processes, including cell growth, differentiation and metabolisms in mammals. Recent studies have indicated that all these effects are mediated by the growth stimulatory effect of T3 to the thyroid hormone nuclear receptors (TRs). Recent studies have reported that the pancreatic  $\beta$  cells also express TRs. KB-141, the TR $\beta$ -selective thyromimetics would show its favorable benefits on  $\beta$ -cells without untoward systemic side effects shown in thyroid hormone. The aim of our study is to clarify the effects of KB-141 on the proliferation of insulin secreting  $\beta$  cells by KB-141.

**Materials and methods:** RINm5, INS-1 cells and isolated primary rodent islets (SD rats) were used in our experiments. Triiodothyronine (T3) and KB-141 were applied to cultured cell lines and isolated primary rodent islets in various concentrations and time intervals along with vehicle only control. At 24, 48 and 72 h of continuous exposure, viable cells were harvested and counted. In isolated rodent islets, Ki-67, insulin and glucagon counter-staining were performed. TR $\beta$ 1 expression, viability, proliferation were analyzed by Western blot, RT-PCR, CCK-8, BrDU, FACS, TUNNEL assay and Trypan Blue negative cell numbers in a Thomas's hemacytometer. Insulin secretory function of exposed  $\beta$ -cells were verified by the amount of insulin mRNA and GSIS.

**Results:** T3 and KB-141 significantly promoted the growth of RINm5, INS-1 cells, and the  $\beta$ -cells in isolated primary islets and improved glucose stimulated insulin secretion.

**Conclusion:** KB-141 would be used as a fundamental diabetes treatment to increase functioning  $\beta$ -cell mass without untoward systemic side effects caused by non-specific thyroid hormone receptor stimulation.

## 890

### Kimchi has favourable effects on metabolic parameters and cytokine levels in patients with type 2 diabetes mellitus

S.-Y. An, M. Lee, J. Jeon, S. Han, H. Kim, D. Kim, K.-W. Lee;

Department of Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, Republic of Korea.

**Background and aims:** Kimchi is a traditional fermented Korean food and it has drawn world-wide interest due to its various beneficial effects. This study demonstrated the beneficial effects of Kimchi on metabolic parameters, cytokine levels, and glucose levels in patients with T2DM.

**Materials and methods:** Twenty patients with T2DM were randomly assigned to two 4-week diet phases, separated by a 2-week washout period (cross-over design). During each diet phase, the subjects consumed portions of either fresh or fermented Kimchi, which were created from the same standardized recipe and ingredients, but differed in terms of fermentation. One-day-old and 10-day-old Kimchi were defined as "fresh" and "fermented" Kimchi, respectively. Diet composition, anthropometric data, glucose levels, lipid parameters, and cytokines levels were analyzed.

**Results:** Fiber intake was significantly increased after ingestion of either type of Kimchi. Diastolic blood pressure decreased significantly from  $73.3 \pm 12.1$  mmHg to  $68.1 \pm 9.5$  mmHg in the fermented Kimchi group. Hemoglobin A1c percentage showed a significant decrease after ingestion of fresh Kimchi from  $6.76 \pm 0.58\%$  to  $6.59 \pm 0.53\%$ . Levels of fibroblast growth factor-21 (FGF21), known to be elevated in patients with T2DM due to FGF-21 resistance, decreased, and levels of adiponectin increased, after ingestion of fermented Kimchi ( $P < 0.05$ ).

**Conclusion:** Kimchi (fresh or fermented) had positive effects on diastolic blood pressure, hemoglobin A1c percentage, levels of metabolic cytokine including FGF-21, and adiponectin levels in patients with T2DM.

## 891

**Effect of natural vanadium-containing Jeju ground water on blood glucose in diabetes patients: a double-blind, randomised controlled trial**G. Koh<sup>1</sup>, D. Lee<sup>1</sup>, S. Lee<sup>1</sup>, E.-K. Kang<sup>1</sup>, H.-J. Han<sup>1</sup>, O.-K. Hwang<sup>1</sup>, S. Kim<sup>1</sup>, E.-J. Yang<sup>1</sup>, M.-K. Kim<sup>1</sup>, H.-J. Chin<sup>2</sup>;<sup>1</sup>Department of Internal Medicine, Jeju National University Hospital,<sup>2</sup>Department of Internal Medicine, Hankook General Hospital, Jeju, Republic of Korea.

**Background and aims:** Several studies have shown that vanadium supplementation enhanced insulin actions and lowered glucose levels in animals and small number of people. The Jeju ground water contains a high concentration of vanadium because Jeju Island is composed predominantly of basalts. We investigated the effect of Jeju ground water on blood glucose profile in patients with diabetes mellitus.

**Materials and methods:** We conducted a 12-week, prospective, double-blind, randomized controlled trial with intention-to-treat analysis. Total 196 patients drank a filtered tap water (C, n=67, vanadium 0 µg/L) transported from the outside of Jeju Island or one of two kinds of Jeju ground water (S1, n=66, vanadium 4–7 µg/L and S2, n=63, vanadium 24 µg/L). They had drunk 1 liter of test waters daily for 12 weeks.

**Results:** Baseline (BL) characteristics and parameters were not different among three groups. HbA1c tended to be decreased over time in S1 & S2 compared with C. However, it was not statistically significant. Fructosamines were significantly decreased at 12 week in S1 and 8 & 12 week in S2 more than C. Fasting plasma glucos (FPG) was significantly decreased at 8 week in S2 more than C (Table). All three groups did not show any significant adverse event

**Conclusion:** The Jeju ground water is likely to improve glucose level in diabetes people. In future, a nation-wide long-term clinical trial is needed to prove its glucose-lowering effect definitely.

Table. Blood glucose variables over time. \* p<0.05 vs C (adjusted for BL value).

Group	Variable	BL	4 week	8 week	12 week
C	HbA1c (%)	7.42±0.14	7.38±0.14	7.40±0.14	7.49±0.15
C	Fructosamine (µmol/L)	290±7	302±7	304±8	308±8
C	FPG (mg/dL)	139±4	143±5	142±4	142±4
S1	HbA1c (%)	7.43±0.13	7.31±0.12	7.35±0.13	7.31±0.12
S1	Fructosamine (µmol/L)	296±5	294±5	295±6	295±6*
S1	FPG (mg/dL)	136±4	131±3	140±6	130±4
S2	HbA1c (%)	7.26±0.12	7.18±0.13	7.09±0.12	7.16±0.13

## 892

**Zinc supplementation improves glycaemic status in uncontrolled type 2 diabetes mellitus**

H.A. Begum, T. Parveen, T. Ara, M.O. Faruque, Q. Nahar; BIRDEM, Dhaka, Bangladesh.

**Background and aims:** Type 2 Diabetes Mellitus is a chronic, progressive illness that causes considerable morbidity and premature mortality. Zn is an essential mineral that is required for various cellular functions. Its abnormal metabolism is related to certain disorders such as diabetic complications. In Bangladesh there have been very few studies, with contradictory results about the zinc effects on diabetes. The aim of the study to assess the effect of zinc on the glycemic control of type 2 diabetes mellitus subjects.

**Materials and methods:** In this clinical trial 89 diabetic patients (type 2) were divided into two groups, randomly. One of them consumed 20mg/day zinc tablet and the other had no zinc supplement. Body mass index, blood pressure, Fasting blood sugar, 2-h post-prandial glucose, serum triglyceride, serum cholesterol, serum low density lipoproteins, serum high density lipoproteins were checked before and after four weeks.

**Results:** During the four weeks of follow-up the Mean ± SD value of age (yrs), waist circumference (inch), hip circumference (inch), BMI (kg/m<sup>2</sup>), SBP (mmHg) and DBP (mmHg) was 52±7.5, 35.6±5.9, 40±5.6, 26.6±5.3, 129±15, 84±10.5 in zinc supplemented group and the values of without zinc supplemented group were 50±7.6, 35.4±5.6, 39.6±4.7, 24.6±3.6, 131±16.5, 85±10.3 respectively. Mean ± SD value of age, waist circumference, hip circumference, BMI, SBP and DBP did not differed between zinc supplementation group and without zinc supplementation group. The Mean ± SD value of HbA<sub>1c</sub> (%), serum LDL (mg/dl), serum HDL (mg/dl) and serum creatinine (mg/dl) was 9.4±1.95, 128±39, 42±10.5, 1.14±0.4 in zinc supplemented group and the values of without zinc supplemented group were 8.22±1.3, 130±32.1, 47.4±9.9, 1.04±0.5 respectively. Serum lipid profile was similar between zinc supplement and without zinc supplement group. Both the fasting (0 day, 12.7±3.2 vs 30<sup>th</sup> day, 10±2.8) and after breakfast (0 day, 16±4.2 vs 30<sup>th</sup> day, 10.2±6) serum glucose in subjects with normal serum triglyceride (TG) levels (<150 mg/dl) were significantly (P<0.01) decreased in zinc supplemented group after four weeks supplementation whereas only serum glucose after breakfast was decreased significantly in subjects with abnormal TG values (> 150 mg/dl). No decreasing tendency was found in subjects without Zinc supplementation. Both the fasting and after breakfast serum glucose levels in subjects with both normal (serum Chol <200 mg/dl, Fasting 13.2±3 vs 10.4±2.7; ABF 17±4 vs 9.4±6.4) and hyper cholesterol group (serum Chol >200 mg/dl Fasting 11.8±3 vs 9.4±2.5; ABF 16±4.3 vs 10±5.4) were significantly decreased in Zinc supplemented group after four weeks supplementation whereas no decreasing tendency was found in subjects without Zinc supplementation. Both the fasting and after breakfast serum glucose levels in subjects with both normal (Fasting 13.4±3 vs 10.4±2.4; ABF 17.7±4.4 vs 12.5±3) and higher waist circumference levels were significantly decreased in Zinc supplemented group (Fasting 12.5 ±3 vs 10.0 ±3.0; ABF 16.2±4.0 vs 8.3±4.0) after four weeks supplementation whereas no decreasing tendency was found in subjects without Zinc supplementation.

**Conclusion:** Our result indicate that Zinc supplementation is significant for improving fasting and post-prandial glycemic control in type 2 diabetes mellitus patients with normal serum TG level.

## 893

**Low consumption of wholegrain products predicts a higher incidence of prediabetes and type 2 diabetes**

A. Björklund, T. Wirstrom, A. Hilding, H.F. Gu, C.-G. Östenson; Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Low intake of wholegrain and fiber have been associated with the development of type 2 diabetes (T2DM). However, data from prospective studies including effects on prediabetic states are scarce. Furthermore an interaction with the TCF7L2 gene has been suggested but not confirmed in new studies. We investigated in a prospective population-based study whether low intake of wholegrain predicts evolution of insulin resistance, pre-diabetes and T2DM. We also tested for modulation by polymorphisms of the TCF7L2 gene.

**Materials and methods:** We examined the 8–10-year incidence of pre-diabetes and T2DM in relation to intake of wholegrain and fiber at baseline among 3180 women and 2297 men aged 35–56 y participating in the Stockholm Diabetes Prevention Program. We used multiple logistic regression analysis to calculate Odds ratios (OR) together with 95% confidence intervals.

**Results:** The risk to deteriorate in glucose tolerance (to pre-diabetes, i.e. IGT and/or IFG, or to T2DM) was increased by 80 % in men with a low intake of wholegrain (OR=1.8, 1.4–2.3). The association remained after adjustment for age, family history of diabetes, BMI, physical activity, smoking, education and blood pressure. Similar, though weaker associations were seen for total intake of fiber. Low intake of wholegrain was correlated with a parameter of insulin resistance (HOMA-IR). A protective effect of wholegrain intake was undetectable in men harbouring diabetogenic polymorphisms of the TCF7L2 gene. In women no significant associations were found between intakes of wholegrain and the risk of pre-diabetes or T2DM.

**Conclusion:** In men low intake of wholegrain predicts development not only of T2DM but also pre-diabetes by mechanisms likely tied to effects on insulin sensitivity. Further, we confirm effect modifications by TCF7L2 genetic polymorphisms.

### A novel hydrophilic derivative of probucol ameliorates glucose tolerance and insulin sensitivity independently of the canonical potency of probucol

L. Miyamoto<sup>1,2</sup>, M. Kono<sup>1</sup>, T. Nakagawa<sup>1</sup>, H. Hattori<sup>2</sup>, K. Ishizawa<sup>1</sup>, H. Nemoto<sup>2</sup>, K. Tsuchiya<sup>1</sup>;

<sup>1</sup>Medical Pharmacology, Inst. of Health Biosciences, <sup>2</sup>Pharmaceutical Chemistry, The University of Tokushima Graduate School, Tokushima, Japan.

**Background and aims:** Probuco is a traditional anti-hyperlipidemic agent harboring marked antioxidant activity. While probucon is extremely hydrophobic, its succinic acid ester, succinobucol, was reported as a water-soluble derivative and was in clinical trials. Succinobucol was shown to be more potent in lipid-lowering, anti-inflammatory and anti-atherogenic effects than probucon in animal models. In addition, succinobucol reduced HbA1c in diabetic patients. Although the clinical trials finally ended in failure, it appears a promising strategy for drug discovery to modulate water-solubility of established active compounds. Meanwhile, we have reported chemical modification of lipophilic agents with symmetrically branched glycerol oligomers (BGL) as a suitable approach to intensify hydrophilicity. Thus we designed and synthesized a novel highly hydrophilic derivative of probucon, Probucon-(glutaric branched-triglycerol)<sub>2</sub> (ProBGL2) and evaluated its effects on glucose and lipid metabolism in high fat diet (HFD)-fed mice.

**Materials and methods:** Lipophilic-hydrophilic balance was assessed by determining octanol-water partition coefficient values (Po/w) using a reversed phase HPLC. Anti-lipid peroxidation activity was estimated by TBARS assay in vitro. 1 g/kg/day of probucon or ProBGL2 were orally administered for a week to male ddY mice at the age of 24 wk fed HFD for 10 wk, and then ipGTT was performed. Insulin level and lipid parameters in the plasma were also determined.

**Results:** Retention time of ProBGL2 was less than one tenth of probucon, suggesting striking improvement of hydrophilicity. In accordance, the Po/w of ProBGL2 was more than 100-times less than that of probucon. However, TBARS assay revealed ProBGL2 possesses far less antioxidant activities against lipid peroxidation than probucon. In HFD-fed mice, while body weight and food intake were not affected, glucose tolerance was much improved by administration of probucon or ProBGL2 (AUC; -50%). Fasting plasma insulin levels and HOMA-IR in the both groups were 70% decreased, suggesting marked amelioration of insulin resistance. However, ProBGL2 did not change plasma total cholesterol concentration though probucon lowered it more than 50%. Furthermore, Plasma triglyceride and NEFA levels were not altered.

**Conclusion:** Our data demonstrate that probucon and its hydrophilic derivative, ProBGL2 ameliorate glucose intolerance and insulin resistance in HFD-fed mice and those are independent of the canonical potency of probucon such as lipid-lowering or antioxidant activities. The effects of ProBGL2 on glucose tolerance and insulin sensitivity were stoichiometrically more than twice as potent as those of probucon. ProBGL2 is suggested to be a novel potent anti-diabetic agent.

## PS 072 Diabetes in childhood

## 895

### Association between growth in early infancy and the development of islet autoimmunity and type 1 diabetes

M. Pflueger<sup>1</sup>, E. Thiering<sup>2</sup>, A. Knopff<sup>3</sup>, J. Stock<sup>3</sup>, J. Heinrich<sup>2</sup>, A.-G. Ziegler<sup>1,3</sup>;

<sup>1</sup>Institute of Diabetes Research, Helmholtz Zentrum München, Klinikum rechts der Isar, Technische Universität München, Neuherberg/Munich,

<sup>2</sup>Institute for Epidemiology I, Helmholtz Zentrum München, Neuherberg/Munich, <sup>3</sup>Forschungsgruppe Diabetes e.V., Neuherberg, Germany.

**Background and aims:** Recent longitudinal epidemiologic studies have suggested that weight gain and weight gain velocity during infancy might have a priming effect on adiposity, blood pressure and asthma later in life. A recent longitudinal study showed an association between weight gain during infancy and onset of asthma in childhood. With a longitudinal model, peak height and weight velocities during the first 2 years of life were analysed. The aim of this study was to evaluate the associations between growth velocity in infancy and the risk of islet autoimmunity and type 1 diabetes.

**Materials and methods:** Data on weight and height were collected at the ages 1, 2, 3, 6, 12 and 24 months from 958 children participating in the BABYDIAB and BABYDIET study, including 106 children who developed persistent islet autoantibodies. All children had a first-degree relative with type 1 diabetes and were prospectively followed from birth for the development of islet autoantibodies defined as one or more autoantibodies to insulin, GAD or IA-2 in two or more blood samples. Individual weight and height growth curves through age 24 months were calculated according to the nonlinear Reed1 model. Peak height velocity (PHV) and peak weight velocity (PWV) were calculated and are defined as the maximum of the first derivatives of the height and weight growths curves, respectively. Age and BMI at adiposity peak and adiposity rebound were derived from cubic mixed models with random effects for two age groups. All models were adjusted for gender.

**Results:** The adiposity peak was significantly associated with the development of islet autoantibodies. There was a linear correlation between the adiposity peak and the risk for the development of one or more islet autoantibodies (one islet autoantibody: HR 0.6 [95% CI 0.4-0.9]; p=0.018 and multiple islet autoantibodies: HR 0.4 [95% CI 0.2-0.8] per 2SD increase; p=0.006). Children's adiposity peak were classified in quartiles which showed that children with a adiposity peak in the first quartile have a significant higher risk for the development of islet autoantibodies compared to children in the 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> quartile (at age 10 years: 1<sup>st</sup> quartile 8.1% vs 2<sup>nd</sup> and 3<sup>rd</sup> quartile 4.4% vs 4<sup>th</sup> quartile 2.9%, p=0.017). The adiposity peak was not associated with the progression to type 1 diabetes. PHV, PWV and adiposity rebound in childhood were not associated with the development of islet autoantibodies, independently from timing and level.

**Conclusion:** These data suggest that an early relative weight gain in the first years of life increase the risk for the development of islet autoimmunity in childhood. The exact mechanisms involved are not yet clear and further examinations are required.

Clinical Trial Registration Number: NCT01115621

### Wrist circumference positively correlates with systolic and diastolic blood pressure in overweight/obese children and adolescents

M. Capizzi<sup>1</sup>, G. Campagna<sup>1</sup>, G. Leto<sup>1</sup>, S. Zampetti<sup>1</sup>, M. Spoletini<sup>1</sup>, C. Venditti<sup>1</sup>, M. Mastantuono<sup>2</sup>, A. Vania<sup>3</sup>, R. Buzzetti<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine and Medical Specialities, Sapienza,

<sup>2</sup>Department of Radiology, Sapienza, <sup>3</sup>Department of Pediatrics, Sapienza, University of Rome, Italy.

**Background and aims:** Cardiovascular diseases are the leading cause of death in Western countries. One of the most important cardiovascular risk factors according to many pathophysiological models is insulin resistance. The wrist circumference, in particular its bone component, has been recently demonstrated to be a clinical marker for insulin-resistance in overweight/obese children, configuring the possibility that this parameter could be taken into account in the measurement of cardiovascular risk. Another risk factor for the developing of cardiovascular disease is blood pressure. Recent studies have shown an acceleration of skeletal growth in children in case of primary

hypertension. In the light of these findings, the aim of the present study was to evaluate the presence of a correlation between wrist circumference and blood pressure in overweight/obese children and adolescents.

**Materials and methods:** N=140 overweight/obese children and adolescents (mean age  $9.8 \pm 2.8$  years), were consecutively recruited for the evaluation of blood pressure, wrist circumference, weight and waist circumference. In all subjects blood samples were taken in order to evaluate insulin and blood glucose and to calculate the HOMA-IR (Homeostasis Model Assessment of Insulin Resistance). The analysis was performed by General Linear Model with the SAS software v.9.2.

**Results:** The wrist circumference was significantly and positively associated with systolic and diastolic blood pressure ( $p < 0.05$  and  $p < 0.0001$  respectively), explaining in the model 10% of the systolic pressure variability and 25% of the diastolic pressure variability.

**Conclusion:** The circumference of the wrist in overweight/obese children and adolescents is correlated with systolic and diastolic blood pressure, confirming that this bone anthropometric marker could be of potential interest for the prediction of cardiovascular risk.

## 897

### Prevalence of type 1 diabetes mellitus in children and adolescents in Germany

J. Rosenbauer<sup>1</sup>, C. Bächle<sup>1</sup>, A. Stahl<sup>1</sup>, K. Castillo<sup>1</sup>, T. Meissner<sup>2</sup>, R.W. Holl<sup>3</sup>, G. Giani<sup>1</sup>, for German Pediatric Surveillance Unit, DPV Initiative, German Competence Network Diabetes mellitus;

<sup>1</sup>Institute for Biometry and Epidemiology, German Diabetes Centre, Düsseldorf, <sup>2</sup>University Children's Hospital Düsseldorf, <sup>3</sup>Institute for Epidemiology and Medical Biometry, Ulm University, Germany.

**Background and aims:** The incidence of type 1 diabetes in children and adolescents has been shown to increase in Germany. Up to date prevalence estimates of type 1 diabetes are a basic requirement for allocation of health care resources for type 1 diabetes care. Aim of the present study was to provide updated estimates on the prevalence of type 1 diabetes in children and adolescents in Germany based on the diabetes incidence register of North Rhine-Westphalia, the most populous German federal state.

**Materials and methods:** Since 1996 newly diagnosed cases of type 1 diabetes have been ascertained with the North Rhine-Westphalian diabetes register by means of three data sources, the prospective hospital-based active surveillance system ESPED, annual inquiries among paediatric, internal and general medical practices, and the computer-based documentation system DPV. The DPV initiative was founded for quality control and scientific research in paediatric diabetes care. Completeness of ascertainment was estimated by the capture-recapture-method. Point and interval estimates (95%-CI) of prevalences (per 100,000 persons) were based on Poisson distribution. Age- and sex-standardized prevalences were estimated by the direct method using equal weights. Poisson regression analysis was applied to assess the effects of age and gender.

**Results:** On 31.12.2010, 4,069 children and adolescents with type 1 diabetes 0-14 years of age and 7,348 children and adolescents 0-19 years of age were registered in North-Rhine Westphalia. The completeness of ascertainment in the both age groups was estimated to be 98.8% (98.4-99.2%) and 98.1% (97.7-98.5%), respectively. The age- and sex-standardized prevalence estimates was 161.8 (156.9-166.8) in the 0-14-year-olds and 207.5 (202.8-212.3) in the 0-19 year-olds, respectively. The prevalences among boys and girls in the age group 0-14 years were quite similar 161.4 (154.4-168.3) vs. 162.3 (155.2-169.5),  $p=0.835$ . In the age group 0-19 years, the prevalence among males was significantly higher than among females (214.9 (208.1-221.6) vs. 199.8 (193.1-199.8),  $p=0.002$ ), owing to a significant male preponderance in the age group 15-19 years (356.2 (340.1-373.0) vs. 298.8 (283.7-314.6),  $p=0.002$ ). The prevalences in the age groups 0-4, 5-9, 10-14, and 15-19 years were 34.8 (30.6-39.1), 152.6 (144.0-161.1), 279.4 (268.6-290.2), and 328.3 (317.0-339.5) ( $p < 0.001$ ), respectively.

**Conclusion:** The North Rhine-Westphalian diabetes register provides valid estimates of type 1 diabetes prevalence in childhood and adolescence in Germany. At present, about 16 and 21 out of 10,000 children and adolescents in the age group 0-14 and 0-19 years, respectively, have type 1 diabetes. Based on the current estimates, overall there are approximately 17,200-18,300 0-14-year-olds and 30,600-32,100 0-19-year-olds with type 1 diabetes in Germany, respectively.

## 898

### Prevalence of increased liver enzymes in 15466 children and adolescents with type 1 diabetes mellitus and type 2 diabetes mellitus in the DPV cohort

M.J. Fritsch<sup>1</sup>, E. Schober<sup>1</sup>, J. Grulich-Henn<sup>2</sup>, T. Meissner<sup>3</sup>, T. Kapellen<sup>4</sup>, D. Dunstheimer<sup>5</sup>, P. Beyer<sup>6</sup>, C. Vogel<sup>7</sup>, E. Molz<sup>8</sup>, R.W. Holl<sup>8</sup>, German Competence Network Diabetes mellitus and the DPV initiative; <sup>1</sup>Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Austria, <sup>2</sup>Center for child and adolescent medicine, Heidelberg University Hospital, Germany, <sup>3</sup>Department of General Pediatrics and Neonatology, University's Children Hospital of Duesseldorf, Germany, <sup>4</sup>Department for Women and Child Health, University of Leipzig, Germany, <sup>5</sup>Clinic for Children and Juveniles, University of Augsburg, Germany, <sup>6</sup>Department of Pediatrics and Adolescent Medicine, Evangelic Hospital Oberhausen, Germany, <sup>7</sup>Clinic for Paediatrics and Adolescent Medicine, Klinikum Chemnitz, Germany, <sup>8</sup>Institute for Epidemiology and medical Biometry, University of Ulm, Germany.

**Background and aims:** A persistent elevation of liver enzymes may be the first indicator of the underlying condition of non alcoholic fatty liver disease (NAFLD). Data about the prevalence of NAFLD in childhood T1DM is rare. The aim of the study was to compare the prevalence of elevated aminotransferases (TAs) in a large cohort of children and adolescents with T1DM and T2DM and investigate possible relations to cardiovascular risk factors.

**Material and methods:** Data of 15201 patients (47.1% female) with T1DM and 265 patients (60.4% female) with T2DM from the German-Austrian DPV (Diabetes Patienten Verlaufsbeobachtung) were included into the analyses. The observation period was from January 1995 to September 2011. Inclusion criteria were an age  $< 20$  years and at least one measurement of TA in the most recent year of treatment. Elevated TAs were defined as ALT and/or AST  $> 50$  U/l. Patients with celiac disease were excluded from the analysis.

**Results:** Patients' median age was 14.5 (10.8-17.2) years vs. 15.9 (14.1-17.3) years with a median HbA1c of 7.9% (7.1-9.1) vs. 6.8% (5.9-8.5) in patients with T1DM and T2DM respectively. In patients with T1DM, 95.4% ( $n=14500$ ) had normal TAs whilst they were increased once in 4.0% ( $n=605$ ) and twice or more in 0.6% ( $n=96$ ). In patients with T2DM, 54% ( $n=143$ ) had normal TAs, which were increased once in 34.3% ( $n=91$ ) and twice or more in 11.7% ( $n=31$ ). In patients with T1DM increased TAs were associated with higher age ( $p < 0.001$ ), HbA1c ( $p < 0.001$ ) and insulin dose ( $p=0.01$ ), shorter stature ( $p < 0.0001$ ), dyslipidaemia ( $p < 0.001$ ) and arterial hypertension ( $p=0.048$ ). No significant association was found between elevated TAs and sex and weight in T1DM. In patients with T2DM, increased TAs were associated with higher age ( $p=0.04$ ) and weight ( $p=0.01$ ), male sex ( $p=0.02$ ), dyslipidaemia ( $p=0.02$ ) and arterial hypertension ( $p < 0.01$ ).

**Conclusion:** In our cohort, the prevalence of elevated liver enzymes was 10 fold higher in children with T2DM compared to children with T1DM. Age and cardiovascular risk factors like dyslipidaemia and arterial hypertension have increased the risk for NAFLD in both, T1DM and T2DM. Insufficient glycemic control and higher daily insulin dose were associated with higher risk for NAFLD in patients with T1DM only, whereas weight and male sex were positively related with NAFLD only in patients with T2DM.

## 899

### The influence of vitamin D analogue on dendritic cells subpopulations in children with type 1 diabetes mellitus

R. Piekarski<sup>1</sup>, L. Szewczyk<sup>1</sup>, J. Tabarkiewicz<sup>2</sup>, J. Roliński<sup>2</sup>;

<sup>1</sup>Pediatric Endocrinology and Diabetology, Medical University in Lublin,

<sup>2</sup>Clinical Immunology, Medical University in Lublin, Poland.

**Background and aims:** In type 1 diabetes dendritic cells (DC) plays an important role in the initiation and modulation of immune response against antigens of pancreatic islet  $\beta$  cells. The aim was evaluation of circulating myeloid dendritic cells (mDC) and plasmacytoid dendritic cells (pDC) in children with type 1 diabetes before and after application of the vitamin D3 analog (Alphacalcidol) in both groups and compared to a group of healthy children.

**Materials and methods:** The study group comprised 50 children, mean age  $10 \pm 5$  years, with newly diagnosed type 1 DM who were randomly enrolled into two groups (treated with vitamin D3 analog or not) and subjected to annual follow-up. In all children were assessed twice the level of 25 (OH) D3, C-peptide and anti-GAD and anti-IA2 antibodies and cell subpopulations were examined using flow cytometry. The reference group consisted of 10 healthy

children. We analyzed the percentage of immature myeloid DC BDCA-1+ / CD19- and plasmacytoid BDCA-2+ / CD123+.

**Results:** In 72% of children who received Alphacalcidol and in 50% without Alphacalcidol, an increase or maintain the value of C-peptide during the annual monitoring as compared with baseline values was observed. In the blood of children with type 1 diabetes not receiving Alphacalcidol the average percentage of myeloid DCs was 0.79% and was significantly higher ( $p < 0.05$ ) than in healthy children (0.26%). However, there were no differences in the percentage of BDCA1 + cells between the group receiving Alphacalcidol and a control group. The percentage of plasmacytoid cells did not differ significantly between groups. The dynamics of changes in the percentage of DC subsets in relation to baseline (newly diagnosed diabetes) was analyzed.

**Conclusion:** The demonstrated differences of the analyzed parameters and the population of immune system cells encouraging more detailed analysis of the observed dependence, because they seem to indicate certain positive elements of used vitamin D3 analog in children with type 1 diabetes.

### The relationship between the quality of daily glycaemic self-monitoring and HbA<sub>1c</sub> in type 1 diabetes mellitus children from Romania, during 2008–2011

V. Serban<sup>1,2</sup>, B. Timar<sup>1,3</sup>, L. Barna<sup>2</sup>, A. Lacatusu<sup>2</sup>, A. Sima<sup>1,3</sup>, M. Rosu<sup>1,3</sup>,  
<sup>1</sup>"Victor Babes" University of Medicine and Pharmacy, Timisoara, <sup>2</sup>"Cristian Serban" Medical Center, Buzias, <sup>3</sup>County Clinical Emergency Hospital, Timisoara, Romania.

**Background and aims:** It has been worldwide observed that obtaining an adequate HbA<sub>1c</sub> value corresponding to an optimal glycemic control in childhood type 1 diabetes mellitus is a difficult challenge. This aspect depends on morphophysiological changes due to age and on many other external factors, including poor medical education and the limited access to an optimal glycaemic self-monitoring. The main aim of our study was to prove the tight inverse correlation between the number of daily self-monitoring tests and HbA<sub>1c</sub> value, which, as we know, is an effective indicator of glycemic control.

**Materials and methods:** We analyzed 1396 admissions of 774 unique patients aged between 1 and 18 years, in our Medical Center between 2008 and 2011. From these patients, 763 were following basal bolus insulin therapy and 11 were on insulin pumps. Patients were grouped according to the number of daily self-monitoring tests prior to admission (stable number for at least 3 months before admission). We analyzed the entire study group characteristics and also, individually for the following age groups: 1 to 6 years old, 7 to 10, 11 to 14 and 15 to 18 years old. The HbA<sub>1c</sub> values were measured for every individual in the second day of admission (using immunoturbidimetric assay method, reference values: 4.6 to 5.9%). Statistics compared the difference between all possible pairs studied (from 0 to 4 self-monitoring tests daily), using ANOVA test for the entire variance and unpaired two-tailed t test for each individual pair.

**Results:** We observed an extremely significant decrease of mean HbA<sub>1c</sub>, with 2.94 % (95%CI from 2.39% to 3.50%,  $p < 0.001$ ) for the entire study group with the increase in the number of daily self-monitoring tests from 0 (mean HbA<sub>1c</sub>: 9.82%) to 4 per day (mean HbA<sub>1c</sub>: 7.98%). Also, a decrease of HbA<sub>1c</sub> was found for every individual age group studied, as following: in 1 to 6 years old an average decrease of 3.15% (95%CI from 1.29% to 5.00%,  $p < 0.001$ ); in 7 to 10 years old group an average of 2.98% (95%CI from 1.97% to 4.00%,  $p < 0.001$ ); in 11 to 14 years old an average decrease of 3.10% (95%CI from 1.97% to 4.23%,  $p < 0.001$ ) and for 15 to 18 years old a decrease of 2.35% (95%CI from 1.31% to 3.40%,  $p < 0.001$ ). For the entire study group, extremely significant reductions were observed between all possible pairs of groups with a daily number of 0, 1, 2, 3 or 4 self-monitoring tests, excluding here the pair with no testing and one daily test, where the differences were only very significant, and the pair containing one and two daily tests between which the differences were not significant.

**Conclusion:** In our patients (children aged between 1 and 18 years) we were able to prove the existence of a strong, inverse correlation between the daily number of glycemic tests and the HbA<sub>1c</sub> values. Excepting one pair of groups (composed by one vs. two daily tests), there were very and extremely significant improvements in the HbA<sub>1c</sub> values for each increase with one test per day. Best results are corresponding to at least four daily tests and the lowest number of still efficient tests is two per day.

## 901

### Insulin sensitivity since the preschool to the school age in severely obese children

M. Manco, M.R. Spreghini, R. Luciano, C. Pensini, R.S. Wietrzycowska, C. Rustico, G.S. Morino;  
 Scientific Directorate, Bambino Gesù Hospital, Rome, Italy.

**Background and aims:** It has been widely described that insulin sensitivity decreases at the puberty, but no information is provided on its earlier time-course. The present study aimed at describing time-course of insulin sensitivity in severely obese children at the transition from the preschool age to the pre-pubertal period.

**Materials and methods:** Retrospective study of 47 severely obese (BMI  $\geq 99^{\text{th}}$  percentile) evaluated between ages 2–6 years and re-evaluated before age 8 years with estimation of glucose tolerance, insulin sensitivity, secretion and glucose disposition index estimated during the oral glucose tolerance test by means of the Whole Body Insulin Sensitivity Index (WBISI), the Insulino-genic Index (IGI); and the Insulin Secretion-Sensitivity Index 2 (ISSI2). Normal weight age- and sex- matched patients undergoing minor surgery served as controls for fasting insulin resistance (Homeostasis Model Assessment of Insulin Resistance, HOMA-IR), lipid profile and liver function tests.

**Results:** Obese patients and controls showed significant different HOMA-IR and lipid profile both at baseline and follow-up ( $p < 0.0001$  for all the comparisons). At follow-up (mean interval  $2.22 \pm 0.66$  years), obese patients showed significant decrease in WBISI ( $p < 0.0001$ ), fasting ( $p = 0.005$ ) and 2 h glucose (2HG,  $p = 0.001$ ). Importantly, 1 child presented at baseline and 4 at follow-up with 2HG between 140 and 199 mg/dl. At stepwise regression models, predictors of WBISI and 2HG at follow-up were changes in BMI z-score ( $R^2 = 0.371$ ;  $p = 0.003$ ;  $\beta = -0.609$ ), and ISS-2 ( $R^2 = 0.411$ ;  $p = 0.001$ ;  $\beta = -0.641$ ), respectively.

**Conclusion:** In obese preschoolers, the decline of insulin sensitivity seems to occur even before the pubertal transition.

## 902

### Interim safety results from a European observational cohort study of children ages 6–12 with type 1 diabetes treated with insulin glulisine (OCAPI study)

M. Konstantinova<sup>1</sup>, V. Loizeau<sup>2</sup>, V. Pilonet<sup>3</sup>, A. Cali<sup>3</sup>, T. Danne<sup>4</sup>;  
<sup>1</sup>University Pediatric Hospital, Sofia, Bulgaria, <sup>2</sup>Lincoln, Boulogne-Billancourt, France, <sup>3</sup>Sanofi, Paris, France, <sup>4</sup>"Auf der Bult" Diabetes Centre for Children, Hannover, Germany.

**Background and aims:** Children with type 1 diabetes (T1DM), particularly younger children, are at risk of clinically significant hypoglycaemia especially when low HbA<sub>1c</sub> levels, missed meals, and increased activity are involved. To enhance our knowledge of the safety of insulin glulisine, we observed children aged 6–12 with T1DM who were given insulin glulisine over a 6-month period in a real-life clinical practice setting, with special focus on those aged 6–8.

**Materials and methods:** OCAPI is an observational, prospective cohort study with 6-month follow-up; interim results were conducted when half of the subjects completed the study. The population comprised children aged 6–12 with T1DM on a stable insulin regimen for  $\geq 3$  months, for which physicians prescribed insulin glulisine. Visits were conducted according to clinical practice; data were recorded after 3 and 6 months of treatment. This analysis included incidence of severe hypoglycaemia in children aged 6–12 (primary objective) with particular focus on the subgroup aged 6–8, as well as symptomatic hypoglycaemia, injection site/systemic hypersensitivity reaction, and medication error in all age groups (secondary objective).

**Results:** Of the 70 patients considered for analysis, 25 were aged 6–8. At inclusion, median duration of insulin treatment was 1.0 y (Q1–Q3: 1.0–3.0) and 2.0 y (Q1–Q3: 1.0–3.0) for the 6–8 and 9–12 groups, respectively; mean HbA<sub>1c</sub> was  $8.0 \pm 1.2\%$  and  $8.3 \pm 1.4\%$ . During the study, number of daily basal insulin injections did not change. Symptomatic documented hypoglycaemia were reported in 56 (81.2%) patients, with similar results among the 6–8 and 9–12 groups. For the on-treatment period, the 6–8 group had higher median number of symptomatic documented hypoglycaemia (18.5) than the 9–12 group (12.0). Incidence rate was numerically higher in the 6–8 group vs the 9–12 group (7573 vs 6676 per 100 patients/y). Overall, incidence of severe hypoglycaemia was 3.0 events per 100 patients/y (Table). Only 1 patient, age 10 y, experienced severe hypoglycaemia, 48 days after insulin glulisine initiation. Injection site reactions ( $n = 16$ ) and medication errors ( $n = 1$ ) occurred only

in the 9–12 group; no patients presented with systemic hypersensitivity reactions. No change in  $HbA_{1c}$  ( $-0.1 \pm 1.5\%$ ) was observed after inclusion.

**Conclusion:** The study reveals that hypoglycaemic events are frequent and occur predominantly in the younger age group. Only 1 severe case of hypoglycaemia was observed, which is encouraging. The incidence of severe hypoglycaemia in children aged 6–12 y treated with insulin glulisine was lower than ranges previously reported in this population (9.4–73 events per 100 patients/y). These data confirm that insulin glulisine is safe in this young population.

Incidence rate of severe hypoglycaemia per 100 patients/year.

	Age Groups		Total
	6 to 8 years old (n=25)	9 to 12 years old (n=45)	(N=70)
Incidence Rate (per 100 patients/year)	0	4.4	3.0
95% CI (Poisson distribution approximation)		[0.1; 24.8]	[0.1; 16.6]

## 903

### The quality of glycaemic control in type 1 diabetes mellitus children from Romania, between 1998–2010

B. Timar<sup>1,2</sup>, V. Serban<sup>2,3</sup>, L. Barna<sup>3</sup>, A. Lacatusu<sup>3</sup>, F. Fiera<sup>3</sup>, A. Sima<sup>1,2</sup>, M. Rosu<sup>1,2</sup>, A. Vlad<sup>1,2</sup>,

<sup>1</sup>County Clinical Emergency Hospital, Timisoara, <sup>2</sup>“Victor Babes” University of Medicine and Pharmacy, Timisoara, <sup>3</sup>“Cristian Serban” Medical Center, Buzias, Romania.

**Background and aims:** Reaching an optimal glycaemic control (according current standards), right after diagnosis and maintaining it for the rest of its life, is the main goal of treatment in children with type 1 Diabetes Mellitus (DM) as it is the most important prevention factor regarding chronic complications and it extends the life expectancy. Unfortunately, in each and every country, this target is extremely difficult to obtain, the quality of glycaemic control must be continuously monitored in order to act promptly where needed. Our study main aim is to evaluate the evolution of  $HbA_{1c}$  values in time, in a representative number of children with type 1 DM from Romania, which we are regarding to be an adequate long term indicator of glycaemic control, in order to reach the information we needed to further correct, where is needed, the existing layout.

**Materials and methods:** To evaluate the long term  $HbA_{1c}$  values behavior (between 1998–2010) in children with type 1 DM, from the entire Romanian area, we enrolled 1718 individuals, aged between 1 and 18 years, all of them being at their first admission in our medical center, the only hospital in country specialized in evaluation, treatment and education of children with type 1 Diabetes Mellitus. The  $HbA_{1c}$  values were measured for each individual in the second day of admission, which we consider to reflect the quality of diseases management obtained in outpatient conditions. Using a retrospective study we analyzed the significance of  $HbA_{1c}$  values variation in the entire 1998–2010 period and the variation between the following periods: 1998–2000; 2001–2003; 2004–2007 and 2008–2010.

**Results:** The decrease of average  $HbA_{1c}$  value from 11.17% (95%CI: 10.71%–11.58%) in 1998 to 8.36% (CI: 8.02%–8.70%) in 2010 is extremely significant, both clinically and statistically; however this value is far from an optimal glycaemic control. The period between 1998 (mean  $HbA_{1c}$  11.17%) and 2000 (mean  $HbA_{1c}$  8.64%) is marked by a significantly yearly decrease of average  $HbA_{1c}$ , followed by a period without significantly variance (2001–2003). The 2004–2007 interval is characterized by an elevated mean  $HbA_{1c}$  compared with the previous period, but with no significant variance within its contained years. Finally, we observed a new extremely significant lowering of  $HbA_{1c}$  mean from 2007 to 2008, followed by a maintaining of mean values until 2010 (8.36%, CI: 8.02%–8.70%).

**Conclusion:** The mean  $HbA_{1c}$  values between 1998 and 2010 for a significant sample for Romania of type 1 DM children decreased extremely significant (with 2.81  $HbA_{1c}$  points,  $p < 0.001$ ). This values reached two minimums, for 2001–2003 (mean  $HbA_{1c}$ : 8.56%, CI 8.15%–8.96%,  $n=356$ ) and 2008–2010 (mean  $HbA_{1c}$ : 8.49%, CI 8.32%–8.66%,  $n=540$ ). Considering that this two minimum values, separated in time, are very alike in spite of a meanwhile enhancement in insulin therapy, of using insulin analog in most of the cases and despite the expanded access to self-monitoring (still dissatisfactory,

though) allows us to suppose that a new improvement of the glycaemic control cannot be reached without complementary methods such as wide access to optimal self-monitoring, a solid education performed by trained teachers and improvement of the economic status of children families.

## 904

### Natural Killer T cells (NKT) in children with new onset type 1 diabetes - preliminary report

L. Szewczyk<sup>1</sup>, R. Piekarski<sup>1</sup>, A. Bojarska-Junak<sup>2</sup>, J. Roliński<sup>2</sup>,

<sup>1</sup>Pediatric Endocrinology and Diabetology, <sup>2</sup>Clinical Immunology, Medical University in Lublin, Poland.

**Background and aims:** Type 1 diabetes is a disease of autoimmune pathogenesis in which different populations of immune cells plays an important role in the initiation and modulation of immune response against antigens of pancreatic islet  $\beta$  cells. NKT cells (natural killer T cells) are a heterogeneous group of cells that plays an important role in the immune response affecting the activity including dendritic cells, T cells, B cells, Tregs through several secreted cytokines. It seems that by their production of Th2 cytokines, NKT may have a protective role against autoimmune diseases, including type 1 diabetes. The aim of our study was to evaluate circulating natural killer T cells (NKT) in children with new onset type 1 diabetes and comparison to a group of healthy children.

**Materials and methods:** The study group comprised 32 children, mean age  $10 \pm 5$  years, with newly diagnosed type 1 diabetes. In all children were assessed C-peptide and anti-GAD and anti-IA2 antibodies to confirm autoimmune pathogenesis of disease and cell subpopulations were examined using flow cytometry. The reference group consisted of 20 healthy children. We analyzed the percentage of NKT3/161+, NKT/4+ cells.

**Results:** In the blood of children with type 1 diabetes the average percentage of NKT was  $51.11 \pm 19.60\%$  and was significantly lower ( $p < 0.05$ ) than in healthy children  $76.56 \pm 16.7\%$ .

**Conclusion:** The demonstrated differences of the analyzed population of immune cells encouraging more detailed analysis of the observed dependence, because they seem to indicate certain disturbances in investigated population of cells in children with type 1 diabetes.

### Study of the outcomes of application of ISPAD versus ADA guidelines of diabetic ketoacidosis in type 1 diabetic children

M.M.F. El Hefnawy, N. Own;

Pediatric Endocrinology, National Institute of Diabetes & Endocrinology, Cairo Egypt

**Background and aims:** Diabetic ketoacidosis (DKA), is the most common and serious complication of type 1 diabetes. There are 2 main guidelines for management of DKA in children under 20 years old. These 2 guidelines are: American Diabetes Association guidelines (ADA), and the International Society of Pediatric and Adolescent Association (ISPAD)/ International Society of Diabetes (IDF) one. The aim of this study was to study the outcomes of application of every one of these 2 guidelines.

**Materials and methods:** Each protocol has been applied on 100 type 1 diabetic child with DKA that had been diagnosed according WHO guidelines. The follow up of both groups were done by doing evaluation of conscious level hourly by Glasgow coma score estimation, in addition to do the following laboratory analysis: ph, serum Bicarbonatr, serum potassium, and all other electrolyte and gas levels, till recovery from the DKA.

**Results:** The results of this study showed that the protocol of fluid therapy according to ISPAD gave better results than the ADA protocol. The insulin therapy outcomes of both of them gave same results, although it was better to delay the insulin therapy for 1 hour after giving the fluid therapy. As regarding the potassium, it was much more significantly better to give the potassium according the ISPAD/IDF protocol as there was significantly less hypokalemia and it was much more better not to stop giving insulin except if potassium level  $< 2.5$  mmol/l.

**Conclusion:** The results of this study directed us to follow the ISPAD/IDF protocol for management of type diabetic children less than 20 years with DKA, starting with fluid therapy. After 1 hour, you can start insulin and potassium therapy and to advise to stop insulin only if its level decreased to less than 2.5 mmol/l.

### 906

**Development of ultra-rapid-acting prandial insulin analogues requires chelation of zinc ions charge masking to increase the rate of subcutaneous absorption**

R. Pohl, R. Hauser, B. Wilson, M. Guinness, M. Jackson, E. De Souza; Bionel Inc, Danbury, USA.

**Background and aims:** Insulin formulations containing EDTA (to sequester the zinc and destabilize the insulin hexamers into monomers/dimers) and citrate (C; to prevent re-association of the monomers by reducing the surface charge) have been effectively used to increase the rate of subcutaneous (sc) absorption of recombinant human insulin (RI) in man when compared to commercial formulations of recombinant human insulin (RHI) or insulin lispro (IL). Furthermore, adding both these excipients to rapid-acting insulin analogs such as IL, aspart or glulisine have been shown to statistically improve the rate of sc absorption relative to the corresponding insulin analogs in diabetic swine. Since the rapid-acting insulin analogs are "less stable" hexamers than RI, it was hypothesized that less EDTA and/or C alone may be sufficient to speed up the rate of absorption. The aim of this study was to use IL as the prototype insulin analog in combination with varying concentrations of EDTA and/or C to optimize the rate of sc absorption in diabetic pigs.

**Materials and methods:** Test formulations consisted of IL, BIOD-200 (IL + 100% EDTA + 100% C), BIOD-226 (IL + 0% EDTA + 100% C), BIOD-236 (IL + 25% EDTA + 87% C) and BIOD-237 (IL + 25% EDTA + 43% C). On the morning of the study, miniature diabetic swine were given a sc dose (0.25 U/kg) of test formulations followed by a meal. Blood glucose and plasma insulin were sampled from -30 to 360 min post dose. Plasma insulin was measured by an ELISA method. The time to maximal concentration ( $T_{max}$ ) and half maximal concentration ( $T_{50\%}$  early,  $T_{50\%}$ ) were calculated for each swine. Results of test formulations were compared to IL.

**Results:** IL dosed to 10 swine had a  $T_{50\%}$  of  $17.6 \pm 3.0$  and  $T_{max}$  of  $35.5 \pm 4.6$  min, which was improved to  $5.4 \pm 0.5^{**}$  and  $22.0 \pm 2.6^*$  min using 100% EDTA and 100% C (BIOD-200,  $n=10$ ;  $*p<0.05$ ,  $**p<0.005$  vs IL). BIOD-226 ( $n=9$ ), with no EDTA, had  $T_{50\%}$  and  $T_{max}$  values of  $15.5 \pm 1.6$  and  $41.1 \pm 7.1$  min, respectively which were comparable to IL demonstrating the need for EDTA. Addition of 25% EDTA + 87% C (BIOD-236;  $n=10$ ) improved the profile to  $9.0 \pm 1.7^*$  ( $T_{50\%}$ ;  $p<0.05$  vs IL) and  $27.0 \pm 4.2$  ( $T_{max}$ ) min. However, reduction of C to 43% (BIOD-237,  $n=4$ ) prolonged the times to  $11.5 \pm 2.5$  ( $T_{50\%}$ ) and  $31.3 \pm 10.1$  ( $T_{max}$ ) min. Concentration vs. time profiles of the first 300 min in diabetic miniature swine are shown in the figure below.

**Conclusion:** Both chelation of zinc ions with EDTA (to disassemble the less stable insulin analog hexamer) and C (to mask the surface charge and prevent re-aggregation) are required to enhance the sc rate of absorption of IL.

Insulin Concentration vs. Time

**Human hyaluronidase + rapid analogue insulin (RAI) improves postprandial glycaemic control in type 2 diabetes compared to insulin lispro alone**

D.C. Klonoff<sup>1</sup>, R. Bergenstal<sup>2</sup>, T. Bailey<sup>3</sup>, D.E. Vaughn<sup>4</sup>, D.B. Muchmore<sup>4</sup>; <sup>1</sup>Mills-Peninsula Diabetes Research Institute, San Mateo, <sup>2</sup>International Diabetes Center, Minneapolis, <sup>3</sup>Advanced Metabolic Care and Research, Escondido, <sup>4</sup>Halozyne Therapeutics, San Diego, USA.

**Background and aims:** Recombinant human hyaluronidase (rHuPH20) accelerates the absorption and action of prandial insulins and reduces postprandial glycemic excursions following liquid test meal administration without increasing the risk of hypoglycemia. Our objective was to compare glycemic control in T2DM using prandial lispro or RAI+rHuPH20 (Analog-PH20) in the outpatient treatment setting.

**Materials and methods:** After a 4-6 week run-in using prandial glulisine + bid glargine, 121 subjects (age  $59 \pm 9.9$  years, BMI  $35.2 \pm 4.4$  kg/m<sup>2</sup>, A1C  $7.1 \pm 0.5\%$ ) were randomized (double blind 2-way crossover) to lispro+rHuPH20 or aspart+rHuPH20 vs lispro alone for two 12 week intensive management periods. Prandial doses were given immediately before meals. The primary endpoint was A1C noninferiority (0.4% margin); postprandial excursions were measured by self monitoring of blood glucose (SMBG) and by continuous glucose monitoring. Overall hypoglycemia was self-reported as SMBG  $\leq 3.9$  mmol/l or symptoms.

**Results:** Changes from baseline A1C were comparable ( $-0.48\%$  for Analog-PH20;  $-0.46\%$  for lispro), with no significant treatment difference (95% CI  $-1.2, +0.5$ ). At the end of treatment, fasting glucose values were similar between treatments (Analog-PH20  $6.85 \pm 1.47$  mmol/l vs lispro  $7.06 \pm 1.49$  mmol/l;  $p=.07$ ). Mean postmeal (90 min) excursions were reduced by 21% ( $p=.0001$ ) over the 12 week period with more subjects consistently (at least 2/3 of meals) achieving values  $<7.8$  mmol/l at breakfast (56.3% vs 35.7%,  $p=.0006$ ) and  $<7.8$  mmol/l at all meals (45.2% vs 28.0%,  $p=.0007$ ). Continuous monitoring over 3 days at the end of treatment showed improved excursion profiles with reduced glycemia throughout daytime hours (Figure). Hypoglycemia rates were comparable between treatments (7.92 episodes  $\leq 3.9$  mmol/l and 1.99 episodes  $<3.1$  mmol/l per subject-month for Analog-PH20 vs 7.66 and 1.78 episodes, respectively for lispro alone,  $p>.25$ ). Total daily insulin dose at the end of treatment ( $123 \pm 67$  for Analog-PH20 vs  $127 \pm 69$  U for lispro,  $p=.31$ ) and amount of weight gain (difference between treatments: 0.21 kg,  $p=.43$ ) were numerically lower for Analog-PH20 compared to lispro alone. Adverse event rates were comparable, and Analog-PH20 was well tolerated. Immunogenicity results showed 4 subjects with pre-existing anti-rHuPH20 antibodies; 2 subjects developed *de novo* anti-rHuPH20 antibodies without any associated adverse events.

**Conclusion:** Compared to insulin lispro alone, coformulation of RAI+rHuPH20 improves postprandial glycemic excursions while maintaining comparable A1C outcomes in an intensive diabetes treatment program.

Clinical Trial Registration Number: NCT01194258

## 908

**Human hyaluronidase provides consistent ultrafast insulin absorption and action over 3 days of continuous subcutaneous infusion**D. Muchmore<sup>1</sup>, L. Morrow<sup>2</sup>, M. Hompesch<sup>2</sup>, D.E. Vaughn<sup>1</sup><sup>1</sup>Halozyne Therapeutics, Inc., San Diego, USA, <sup>2</sup>Profil Institute for Clinical Research, Chula Vista, USA.

**Background and aims:** Rapid acting insulin analogs (RAI) demonstrate systematic variation in insulin absorption and action as infusion sites age. Euglycemic clamp studies were conducted to test the effect of human hyaluronidase (rHuPH20) on the variability of insulin aspart absorption and action as a function of infusion site age.

**Materials and methods:** Euglycemic clamps following bolus infusion of insulin aspart (100 U/ml, 0.15 U/kg) were performed as a function of infusion site age in 2 cohorts of generally healthy adult type 1 pump patients in a randomized, double blind, crossover study. In one cohort rHuPH20 (600 U/ml) was coformulated ("Coform" cohort) with insulin aspart (100 U/ml), while in the other cohort rHuPH20 (150 U in 1 ml) was injected through the new infusion set immediately after insertion and prior to any insulin infusion ("Pre-Rx" cohort).

**Results:** Consistent with previous reports, absorption kinetics and insulin action of RAI alone varied considerably with infusion site age; the fraction of insulin exposure occurring within 1 hr following bolus infusion was as little as 15% for a new infusion site and doubled to ~30% after 3 days of use. Similarly, both the onset (early  $t_{GIR50\%}$ ) and duration (calculated analogous to Mean Residence Time) of insulin action varied by up to 30 minutes as the infusion site aged. Coformulation of insulin aspart with rHuPH20 accelerated insulin absorption and action across infusion site use relative to insulin aspart alone, although the early exposure did change from ½ day to 2½ days of continuous infusion of the coformulation. Preadministration of rHuPH20 provided a consistent ultrafast profile over 3 days of infusion site use, eliminating the variability in insulin absorption and action associated with infusion site aging.

**Conclusion:** rHuPH20 accelerates insulin absorption and action following bolus infusion and reduces the variability in insulin absorption and action kinetics associated with infusion site aging.

Cohort	Infusion Site Age	Insulin Aspart Alone			With rHuPH20		
		Early Exposure (% of Total)	Onset of Action (min)	Duration of Action (min)	Early Exposure (% of Total)	Onset of Action (min)	Duration of Action (min)
Coform	1/2 day	21	47	164	35	35	147
Coform	2 1/2 days	33	35	147	51	40	133
Pre-Rx	<2 h	15	60	180	31	34	139
Pre-Rx	1 day	22	34	164	37	32	134

Clinical Trial Registration Number: NCT01275131

## 909

**Steady state is reached within two to three days of once-daily administration of ultra-long-acting insulin degludec**H.-V. Coester<sup>1</sup>, T. Heise<sup>1</sup>, L. Nosek<sup>1</sup>, C. Roepstorff<sup>2</sup>, S. Segel<sup>3</sup>, N. Lassota<sup>2</sup>, H.L. Haahr<sup>2</sup><sup>1</sup>Profil Institut für Stoffwechselforschung, Neuss, Germany, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>3</sup>Novo Nordisk A/S, Aalborg, Denmark.

**Background and aims:** The objective of basal insulin therapy is to ensure continuous insulin coverage throughout the 24 hours of the day. When insulins with a duration of action of 24 hours or less are used once daily, they are characterised by action profiles with periods of low action rising to a peak/plateau followed by a decline. Such profiles will only provide partial basal coverage implying clinical challenges in ensuring consistent glucose control throughout 24 hours. Insulin degludec (IDeg) has a duration of action extending beyond 42 hours leading to a flat and stable action profile at steady state. It is important for clinical evaluation at initiation and titration of treatment to estimate the time to reach steady state with IDeg.

**Materials and methods:** Subjects with type 1 and type 2 diabetes from two separate randomised, double-blind trials, (T1D/T2D;  $n=66/49$ ; age 37/59 years, BMI 25/30 kg/m<sup>2</sup>, HbA<sub>1c</sub> 8.1/7.6%) received IDeg at 0.4, 0.6 or 0.8 U/

kg for 8 (T1D) or 6 (T2D) days. Blood samples were taken before each dosing to determine the serum IDeg concentration on each day relative to the serum IDeg concentration before dosing on Day 7 (T1D) or 5 (T2D). The clinically relevant time to steady state was estimated as time from first dose until serum IDeg trough concentrations exceeded 90% of the final plateau level. **Results:** For all subjects, independent of dose or type of diabetes, steady state was reached after 2-3 days of IDeg dosing (Fig. 1). At steady state, exposure of IDeg was unchanged from day to day. **Conclusion:** Steady-state kinetics were observed with stable serum IDeg concentrations reached within 2-3 days of once-daily dose administration with no further increase in exposure thereafter.

**Fig 1. Relative serum IDeg trough concentrations (estimated ratios and 95% CIs) during initiation of once-daily dosing in subjects with T1DM (A) and T2DM (B).**

**Altering the timing of once-daily dosing of insulin degludec achieves similar glycaemic control and safety to dosing at the same time each day in patients with type 1 diabetes**

D. Russell-Jones<sup>1</sup>, P. Hollander<sup>2</sup>, B. Miranda-Palma<sup>3</sup>, J.G. Cooper<sup>4</sup>, E. Franek<sup>5</sup>, S. Bain<sup>6</sup>, C.B. Djurhuus<sup>7</sup>, S.C. Tamer<sup>7</sup>, C. Mathieu<sup>8</sup>;

<sup>1</sup>Royal Surrey County Hospital & University of Surrey, Guildford, UK, <sup>2</sup>Baylor University Medical Center, Dallas, USA, <sup>3</sup>University of Miami, Miller School of Medicine, USA, <sup>4</sup>Stavanger University Hospital, Norway, <sup>5</sup>Central Clinical Hospital MSWiA, Warsaw, Poland, <sup>6</sup>Abertawe Bro Morgannwg University NHS Trust, Singleton Hospital, Swansea, UK, <sup>7</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>8</sup>UZ Gasthuisberg, KU Leuven, Belgium.

**Background and aims:** To date, consistent timing of basal insulin injection is needed to ensure stable day-to-day glycaemic control. Insulin degludec (IDeg) provides an ultra-long, flat action profile, enabling flexible dosing to accommodate an individual patient's lifestyle. The primary objective of this study was to confirm the efficacy of IDeg administered in a flexible dose regimen (IDeg Flex). A secondary objective and the topic of this report was to compare whether a flexible dosing regimen (IDeg Flex) provided comparable safety and efficacy to IDeg dosed at the same time each day (IDeg OD).

**Materials and methods:** In this 26-week, open-label, randomised, treat-to-target trial in patients with type 1 diabetes, IDeg OD (n=165) administered with the evening meal, was compared to a forced-flexible dosing regimen of IDeg Flex (n=164) where subjects alternated insulin administration timing between morning and evening to create intervals of a minimum of 8 and a maximum of 40 hours between insulin doses.

**Results:** Mean baseline values for HbA<sub>1c</sub> (both groups 7.7%), fasting plasma glucose (FPG) (9.6 vs. 10.0 mmol/L), disease duration (17.3 vs. 20.0 years), age (42.6 vs. 44.5 years), and BMI (27.0 vs. 26.4 kg/m<sup>2</sup>) were comparable between IDeg Flex and IDeg OD groups, respectively. At 26 weeks, 84% of individuals in both groups completed the trial. Both IDeg Flex and IDeg OD reduced HbA<sub>1c</sub> by 0.4%-points (estimated treatment difference [ETD] IDeg Flex-IDeg OD: 0.01% [95% CI: -0.13; 0.14]). Observed FPG reductions were greater with IDeg OD (-1.28 mmol/L with IDeg Flex and -2.54 mmol/L with IDeg OD (ETD IDeg Flex-IDeg OD: 0.95 mmol/L [95% CI: 0.15; 1.75])). Overall hypoglycaemia rates (PG <3.1 mmol/L or severe hypoglycaemia requiring assistance) were similar between IDeg Flex and IDeg OD groups (82.4 vs. 88.3 events/patient-year, respectively; estimated rate ratio (ERR) IDeg Flex:IDeg OD 0.92 [95% CI: 0.76; 1.12])). Rates of nocturnal hypoglycaemia (time of onset between 00:01 and 05:59 hours, inclusive) were significantly lower with IDeg Flex compared with IDeg OD (6.2 vs. 9.6 events/patient-year, respectively; ERR: 0.63 [95% CI: 0.46; 0.86])). Severe hypoglycaemia rates were similar for both groups, as were adverse event rates. Final IDeg doses were 0.42 (IDeg Flex) and 0.38 (IDeg OD) U/kg per day.

**Conclusion:** IDeg can be administered in a once-daily regimen but at a different time from day to day with no difference in glycaemic control or safety compared to standard OD dosing in patients with type 1 diabetes. Greater dosing flexibility may represent a major improvement in patient convenience by allowing injection times to be changed daily according to needs of the individual.

## 911

**Insulin degludec allows for flexible daily dosing in type 1 diabetes, providing equal glycaemic control with less nocturnal hypoglycaemia than insulin glargine over 52 weeks**

J.G. Cooper<sup>1</sup>, C. Mathieu<sup>2</sup>, P. Hollander<sup>3</sup>, B. Miranda-Palma<sup>4</sup>, E. Franek<sup>5</sup>, S. Bain<sup>6</sup>, J. Larsen<sup>7</sup>, S.C. Tamer<sup>7</sup>, D.L. Russell-Jones<sup>8</sup>;

<sup>1</sup>Department of Medicine, Stavanger University Hospital, Stavanger, Norway, <sup>2</sup>UZ Gasthuisberg, KU Leuven, Belgium, <sup>3</sup>Baylor University Medical Center, Dallas, USA, <sup>4</sup>University of Miami, Miller School of Medicine, Miami, USA, <sup>5</sup>Central Clinical Hospital MSWiA, Warsaw, Poland, <sup>6</sup>Abertawe Bro Morgannwg University NHS Trust, Singleton Hospital, Swansea, UK, <sup>7</sup>Novo Nordisk, Søborg, Denmark, <sup>8</sup>Royal Surrey County Hospital & University of Surrey, Guildford, UK.

**Background and aims:** Current basal insulin preparations must be injected at the same time every day to ensure stable glycaemic control, particularly in patients with type 1 diabetes. Insulin degludec (IDeg) is an ultra-long-acting basal insulin that forms soluble multi-hexamers upon s.c. injection, resulting

in a flat and stable glucose-lowering effect. This profile may enable flexible intervals between daily doses. The objective of this study was to investigate whether flexible dosing of IDeg provided comparable efficacy and safety to insulin glargine (IGlar) dosed at the same time each day.

**Materials and methods:** This 26 + 26-week (main + extension period), open-label, treat-to-target trial in patients with type 1 diabetes (n=493) compared once-daily (OD) IDeg (with evening meal) or IGlar (at same time each day) to a flexible IDeg regimen (IDeg Flex), each in combination with meal-time insulin aspart. In the first 26 weeks, IDeg Flex patients were required to alternate OD insulin administration between morning and evening, thus creating intervals of a minimum of 8 and a maximum of 40 hours between doses. For the 26-week extension, IDeg OD and IDeg Flex patients were allocated to IDeg Free Flex (IDeg FF; n=329), which allowed dosing at any time of day with dose intervals between 8 and 40 hours, and compared to IGlar (n=164), which was continued as per label. Herein, we report data for IDeg FF and IGlar at 52 weeks.

**Results:** Mean baseline characteristics were comparable between groups (mean age 43.7 years, diabetes duration 18.5 years, HbA<sub>1c</sub> 7.7% and fasting plasma glucose [FPG] 9.8 mmol/L). At 52 weeks, IDeg FF and IGlar reduced baseline HbA<sub>1c</sub> by 0.13 and 0.21%-points (estimated treatment difference [ETD] IDeg FF-IGlar: 0.07% [95% CI: -0.05; 0.19])). FPG reductions were significantly greater with IDeg FF versus IGlar (ETD IDeg FF-IGlar: -1.07mmol/L [95% CI: -1.82; -0.32])). Overall hypoglycaemia rates (PG <3.1mmol/L or severe hypoglycaemia requiring assistance) were similar (68.1 vs. 63.4 events/patient-year for IDeg FF and IGlar, respectively; estimated rate ratio (ERR) IDeg FF:IGlar 1.09 [95% CI: 0.91; 1.29])). Nocturnal hypoglycaemia was significantly 25% lower for IDeg FF versus IGlar (ERR: 0.75 [95% CI: 0.58; 0.97])), and severe hypoglycaemia was 26% lower (ERR: 0.74 [95% CI: 0.38; 1.42])). Adverse event rates were low in both groups. Basal insulin doses did not differ; 0.40 (IDeg FF) and 0.42 (IGlar) U/kg at 52 weeks.

**Conclusion:** This study demonstrates that IDeg can be administered conveniently at any time of day with similar glycaemic control and less nocturnal hypoglycaemia than standard IGlar given OD at the same time each day over 52 weeks in patients with type 1 diabetes. A flexible dosing regimen could make it easier for patients to incorporate their insulin into changing daily routines and may improve patient adherence.

## 912

**Insulin degludec 200 U/ml is ultra-long-acting and has a flat and stable glucose-lowering effect**

U. Hövelmann<sup>1</sup>, T. Heise<sup>1</sup>, L. Nosek<sup>1</sup>, S.G. Böttcher<sup>2</sup>, H. Hastrup-Nielsen<sup>2</sup>, H.L. Haahr<sup>2</sup>;

<sup>1</sup>Profil Institut für Stoffwechselforschung, Neuss, Germany, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark.

**Background and aims:** Insulin degludec (IDeg) is a new-generation, ultra-long-acting basal insulin, which is developed as both 100 U/ml and 200 U/ml formulations in order to accommodate the wide range of insulin dose requirements characteristic of diabetes mellitus, especially type 2 diabetes. With IDeg 200 U/ml, up to 160 U of IDeg can be administered in a single injection using a newly developed prefilled pen.

**Materials and methods:** We investigated the pharmacodynamic and pharmacokinetic properties of 0.6 U/kg IDeg 200 U/ml in subjects with type 2 diabetes (n=16, mean: BMI, 30 kg/m<sup>2</sup>; HbA<sub>1c</sub>, 7.3%) who received IDeg 200 U/ml once daily over 6 days. On Day 6 while at steady state, a 26-hour euglycaemic glucose clamp was conducted (Biostator; clamp blood glucose level: 5 mmol/l).

**Results:** As previously shown for IDeg 100 U/ml, the mean glucose infusion rate (GIR) profile for IDeg 200 U/ml was flat and stable over the dosing interval tau (Fig. 1). The glucose-lowering effect of IDeg was evenly distributed over the dosing interval, with AUC<sub>GIR</sub> for each of the two 12-hour intervals being approximately 50% of the total AUC (AUC<sub>GIR,tau,SS</sub>). The effect of IDeg extended beyond 26 hours in all subjects, as blood glucose stayed close to the target level throughout the clamp. The terminal half-life at steady state was 26.2 hours. IDeg 200 U/ml was well tolerated, no injection site reactions were reported and no safety concerns were identified.

**Conclusion:** IDeg 200 U/ml has a flat and stable glucose-lowering effect in people with type 2 diabetes.

Fig. 1: Mean 24-hour GIR profile of IDeg 200 U/ml at steady state

## 913

**Steady-state pharmacokinetics (PK) and glucodynamics (GD) of the novel, long-acting basal insulin LY2605541 in patients with type 2 diabetes mellitus**

T. Heise<sup>1</sup>, D.C. Howey<sup>2</sup>, V.P. Sinha<sup>2</sup>, S.L. Choi<sup>2</sup>, K.F. Mace<sup>2</sup>;

<sup>1</sup>Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany, <sup>2</sup>Eli Lilly and Company, Indianapolis, USA.

**Background and aims:** The basal insulin LY2605541 (LY) is PEGylated insulin lispro designed to have a large hydrodynamic size which delays insulin absorption and reduces clearance, resulting in prolonged duration of action. This parallel group, open-label, dose escalation study examined the PK and GD of LY after multiple-dose administration.

**Materials and methods:** Fixed-doses of LY (3-9 nmol/kg) were given once-daily (QD) for 14 days to insulin-treated patients with T2DM (N=32 [30 M/2 F; 8 patients per arm]; mean [SD] age, 56 [6] yrs; BMI, 31.0 [2.4] kg/m<sup>2</sup>; HbA1c, 7.8 [0.4] %). A 24-h euglycemic glucose clamp was conducted on Days 1 and 14.

**Results:** Pharmacokinetic steady state was achieved within 7-10 days and the peak to trough fluctuation was <1.5 which translated to a nearly "peakless" glucose infusion rate at steady state and a duration of action of at least 24 h [Figure]. Based on AUC, there was a gradual build up of mean LY concentrations (8.4-fold higher vs. single dose). Across dose levels  $t_{1/2}$  ranged from 44.7-75.5 h (~2-3 days). As steady state was achieved there were dose-dependent reductions in the prandial insulin dose and in fasting blood glucose, which decreased to 60-100 mg/dL across dose levels. The nocturnal glucose control between 3 am and 9 am was unchanged. No severe or prolonged hypoglycemia was reported. Mild hypoglycemia was the most common adverse event.

**Conclusion:** In this Phase 1 study of fixed LY doses without titration, LY was well-tolerated and demonstrated a flat PK and GD profile accompanied by glucose normalization, prandial insulin dose reduction, and no severe hypoglycemia.

## 914

**Effects of a novel PEGylated basal insulin, LY2605541, on hepatic glucose output and muscle glucose uptake: simulations based on data from euglycaemic clamp studies**

B.G. Topp<sup>1</sup>, J.S. Geiser<sup>1</sup>, D.K.W. Soon<sup>1</sup>, T. Heise<sup>2</sup>, M.D. Michael<sup>1</sup>, S.J. Jacober<sup>1</sup>, J.M. Beals<sup>1</sup>, V.P. Sinha<sup>2</sup>;

<sup>1</sup>Eli Lilly and Company, Indianapolis, USA, <sup>2</sup>Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany.

**Background and aims:** LY2605541 (LY) is insulin lispro with a 20 kDa polyethylene glycol (PEG) moiety covalently attached to lysine B28. LY is designed to have a large hydrodynamic size that slows absorption and reduces clearance, resulting in a longer duration of action. The glucodynamics have been previously assessed in two studies, a single dose study in healthy volunteers (HV) and a multiple-dose study in patients with type 2 diabetes mellitus (T2DM). This *in silico* study sought to characterize the physiologic effects and tissue distribution of LY2605541 using pharmacokinetic and pharmacodynamic data obtained from human studies in an established model of human physiology (Metabolism Physioblab® platform).

**Materials and methods:** The pharmacokinetic impact of LY's size was described using a pharmacokinetic tissue distribution model; a model was developed for both LY and insulin glargine based on transit rate through the capillaries and the lymphatic system. The effects of LY and glargine on glycemic control, hepatic glucose output (HGO) and muscle glucose uptake (MGU) were predicted using the Metabolism Physioblab® platform, a proprietary model calibrated to over 3000 papers and validated against 300 publications.

**Results:** After single doses (0.5–0.8 U/kg of insulin glargine, or 0.3–2.2 U/kg of LY) in HV, glargine concentrations were predicted to be similar in plasma, liver and muscle while LY concentrations were predicted to be higher in liver than muscle (11.2 vs. 2.4 µU/mL at 2.2 U/kg LY) due to a slower transit across the capillary bed relative to lymph flow. Glucose infusion rates (GIR) were similar (140 vs. 149 mg/min) for 0.5 U/kg insulin glargine and 2.2 U/kg LY. However, their predicted effects at the liver (ΔHGO, -52, -129 mg/min) and muscle (ΔMGU, 87, 19 mg/min), differed. After multiple, daily doses (0.33–1 U/kg) in patients with T2DM, LY gradually increased to reach steady-state concentrations (88 vs 22 µU/mL for liver vs muscle for a 0.5 U/kg dose) in approximately a week. LY predominantly inhibited HGO (GIR = 147, ΔHGO = -124, ΔMGU 24 mg/min for 0.5 U/kg). Thus, LY is predicted to regulate fasting glucose levels largely by inhibiting HGO while glargine is predicted to regulate fasting glycemia largely by inhibition of HGO and stimulation of MGU.

**Conclusion:** These simulation results suggest that LY2605541 has a preferential hepatic effect and its effect on MGU is predicted to be less than insulin glargine. Clinical trials are planned to test these model predictions.

## 915

**Liver preferential effects of an insulin analogue demonstrated by insulin receptor phosphorylation and glucose dynamics in insulin target tissues *in vivo***

C.L. Brand, S.D. Bouman, J. Kildegaard, T.B. Kjeldsen, P. Madsen, H. Naver, C.B. Jeppesen, J.J. Fels, J. Sturis, E. Nishimura;  
Diabetes Research Unit, Novo Nordisk A/S, Maaloev, Denmark.

**Background and aims:** Compared to the distribution of endogenously secreted insulin throughout the body, subcutaneous (sc) insulin is distributed in a non-physiological manner to the insulin target tissues with the peripheral tissues being relatively overexposed to insulin compared to the liver, resulting in increased risk of hypoglycaemia. The present study investigates a novel insulin analogue (insulin 327) and its potential liver preferential effects compared to human insulin (HI) in rodents.

**Materials and methods:** Insulin receptor phosphorylation (pIR) was measured in liver, muscle and fat tissues at 0, 5, 15, 60, 120 and 180 min after intravenous (iv) injection of either HI or insulin 327 in conscious male NMRI mice. The dynamic rates of glucose uptake (GU) and hepatic glucose production (HGP) were determined by <sup>3</sup>H-glucose techniques during 5 hrs of three different constant iv infusion rates of either HI or insulin 327 and variable glucose infusion rates (GIR) to maintain euglycemic clamp in conscious male Sprague Dawley rats. The potency of insulin 327 relative to HI was calculated as the ratio between their ED<sub>50</sub> values calculated by fitting the insulin infusion rates and the corresponding response values to Sigmoidal curves.

**Results:** For similar glucose lowering in mice, insulin 327 exerted a liver preferential pIR pattern as the response in liver accounted for 71% of the com-

bined pIR response (AUC) in all tissues compared to 43% for HI. The potency of insulin 327 on GIR during the last hr of the clamp in rats was 59% relative to HI. The potency of insulin 327 relative to HI on ΔAUCs for HGP and GU was 77% and 37%, respectively, indicating a more potent suppression of HGP than stimulation of GU.

**Conclusion:** These data demonstrate that insulin 327 exerts liver preferential pIR and glucose dynamic patterns compared to HI in rodents, and may therefore represent a novel basal insulin regimen with a potential for improving the hypoglycaemia safety margin.

#### Better glycaemic control and weight loss with the novel long-acting PEGylated basal insulin LY2605541 compared with insulin glargine in patients with type 1 diabetes

T. Blevins<sup>1</sup>, J. Rosenstock<sup>2</sup>, R.M. Bergenstal<sup>3</sup>, L.A. Morrow<sup>4</sup>, M.J. Prince<sup>5</sup>, Y. Qu<sup>5</sup>, V.P. Sinha<sup>5</sup>, D.C. Howey<sup>6</sup>, S.J. Jaber<sup>6</sup>;  
<sup>1</sup>Texas Diabetes and Endocrinology, Austin, <sup>2</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, <sup>3</sup>International Diabetes Center at Park Nicollet, Minneapolis, <sup>4</sup>Profil Institute for Clinical Research, Inc, Chula Vista, <sup>5</sup>Eli Lilly and Company, Indianapolis, <sup>6</sup>Eli Lilly and Company, retired, Indianapolis, USA.

**Background and aims:** The basal insulin analogue LY2605541 (LY) is PEGylated insulin lispro designed to have a large hydrodynamic size which delays insulin absorption and reduces clearance, resulting in prolonged duration of action. Primary aim of this Phase 2, randomised, open-label, 2x2 crossover study was to determine if LY was noninferior (margin of 0.6 mmol/L) to glargine (GL) for daily mean blood glucose (BG) in treatment of T1D.

**Materials and methods:** Patients (N=137) received basal insulin (LY or GL) once daily, plus prandial insulin, for 8 weeks, followed by crossover treatment for 8 weeks. Daily mean BG was obtained from three 8-point self-monitored BG profiles (pre- and 2 hrs post-meal, at bedtime, and 3 AM) the week prior to each visit.

**Results:** After 8 weeks, LY was non-inferior and also superior to GL in daily mean BG ( $\pm$  SEM:  $8.01 \pm 0.14$  vs  $8.43 \pm 0.17$  mmol/L, LS mean difference =  $-0.55$  mmol/L; 90% CI  $[-0.81, -0.29]$ ,  $p < .001$ ). Fasting BG variability (SD;  $2.70 \pm 0.10$  vs  $3.16 \pm 0.12$  mg/dL,  $p < .001$ ) and  $HbA_{1c}$  ( $-0.59$  vs  $-0.43\%$ ,  $p < .001$ ) were reduced with LY compared with GL. Prandial insulin dose was reduced during LY treatment (from 0.225 to 0.187 U/kg/day) and increased (to 0.242 U/kg/day) with GL ( $p < .001$ ). LY was associated with weight loss and GL with weight gain (LS means  $-1.2$  vs  $+0.7$  kg,  $p < .001$ ). Total hypoglycaemia rate was higher for LY (8.7 vs 7.4 events/30 days,  $p = .04$ ), but nocturnal hypoglycaemia rate was lower (0.9 vs 1.1 events/30 days,  $p = .01$ ). Adverse events (including severe hypoglycaemia) were similar, although more mild gastrointestinal-related events (dyspepsia, nausea, abdominal distension) occurred with LY (15 vs 4%,  $p < .001$ ). During LY treatment, mean changes were higher for ALT, AST, triglycerides and LDL-cholesterol and lower for HDL-cholesterol compared to GL (all  $p < .02$ ), but all mean changes remained within normal range.

**Conclusion:** LY provided greater improvements in glycaemic control and reduced nocturnal hypoglycaemia vs GL in T1D. Notably, this was accompanied by reduced weight and lowering of prandial insulin doses.

*Clinical Trial Registration Number:* NCT01049412

### 917

#### Weight loss and lower nocturnal hypoglycaemia with novel long-acting basal insulin LY2605541 versus insulin glargine in patients with type 2 diabetes

R.M. Bergenstal<sup>1</sup>, J. Rosenstock<sup>2</sup>, R.F. Arakaki<sup>3</sup>, M.J. Prince<sup>4</sup>, Y. Qu<sup>4</sup>, V.P. Sinha<sup>4</sup>, D.C. Howey<sup>4</sup>, S.J. Jaber<sup>4</sup>;  
<sup>1</sup>International Diabetes Center at Park Nicollet, Minneapolis, <sup>2</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, <sup>3</sup>University of Hawaii at Manoa, Honolulu, <sup>4</sup>Eli Lilly and Company, Indianapolis, USA.

**Background and aims:** The basal insulin analogue LY2605541 (LY) is PEGylated insulin lispro designed to have a large hydrodynamic size which delays insulin absorption and reduces clearance, resulting in prolonged duration of action. This 12-week, Phase 2, randomised, open-label, parallel study evaluated whether self-monitored fasting blood glucose (FBG) was lower with once-daily LY than insulin glargine (GL).

**Materials and methods:** Patients converted to AM insulin administration during lead-in and were randomised 2:1 to AM administration of LY (n=195) or GL (n=93) from basal insulin (GL: n=248, NPH insulin: n=39).

**Results:** At baseline, for LY vs. GL, mean  $\pm$  SEM FBG was  $8.149 \pm 0.16$  vs.  $7.79 \pm 0.23$  mmol/L,  $HbA_{1c}$  was  $7.7 \pm 0.1$  vs.  $7.8 \pm 0.1\%$ , and weight was  $90.7 \pm 1.4$  vs.  $89.7 \pm 2.1$  kg. At Week 12, LY vs. GL resulted in similar mean FBG ( $6.56 \pm 0.11$  vs.  $6.49 \pm 0.15$  mmol/L,  $p = .433$ ), and mean  $HbA_{1c}$  ( $7.0 \pm 0.06$  vs.  $7.2 \pm 0.09\%$ ,  $p = .279$ ). Intra-day blood glucose variability, as measured by 8-point self-monitored blood glucose standard deviation, was reduced with LY (1.91

$\pm 0.06$  vs.  $2.17 \pm 0.10$  mmol/L,  $p = .031$ ). LY patients had significant mean weight loss ( $0.58 \pm 0.16$  kg,  $p = .007$ ), while GL patients gained weight ( $0.31 \pm 0.18$  kg,  $p = .66$ ; least-squares mean difference:  $-0.84$  kg,  $p = .001$ ). Mean hypoglycaemia rate (#/30d) with LY was not different compared to GL (total: 1.34 vs. 1.52;  $p = .80$ ; nocturnal: 0.25 vs. 0.39,  $p = .18$ ). After adjusting for baseline nocturnal hypoglycaemia, LY patients had a 48% rate reduction in nocturnal hypoglycaemia events compared to GL ( $p = .021$ ). Adverse events were similar across treatments. Mean increases in alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were higher with LY versus GL ( $p < .01$ ), but remained in normal range. Triglyceride (TG) change from baseline was not significant for either group, but endpoint TGs were higher with LY vs. GL ( $p < .01$ ). There was no difference in LDL-C or HDL-C between treatments.

**Conclusion:** In conclusion, LY provided similar glycaemic control, with reduced intra-day variability and lower nocturnal hypoglycaemic events compared to GL in patients with type 2 diabetes. While improving glycaemic control, LY resulted in weight loss.

### 918

#### Contrasting weight changes with LY2605541, a novel long-acting insulin, and insulin glargine despite similar improved glycaemic control in type 1 diabetes and type 2 diabetes

S.J. Jaber<sup>1</sup>, J. Rosenstock<sup>2</sup>, R.M. Bergenstal<sup>3</sup>, M.J. Prince<sup>1</sup>, Y. Qu<sup>1</sup>, J.M. Beals<sup>1</sup>;

<sup>1</sup>Eli Lilly and Company, Indianapolis, <sup>2</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, <sup>3</sup>International Diabetes Center at Park Nicollet, Minneapolis, USA.

**Background and aims:** The basal insulin analogue LY2605541 (LY) is a PEGylated insulin lispro designed to have a large hydrodynamic size which delays insulin absorption and reduces clearance, resulting in prolonged duration of action. Improved glycaemic control with insulin generally results in weight gain. However, once-daily LY showed glycaemic control comparable with or superior to insulin glargine (GL), and resulted in weight loss compared with weight gain with GL.

**Materials and methods:** Weight change was examined in 2 Phase 2, randomised, open-label trials comparing LY and GL: a 12-wk study in patients (N=288) with type 2 diabetes (T2D) and an 8-wk 2x2 crossover study in patients (N=137) with type 1 diabetes (T1D).

**Results:** In the T2D trial, patients lost 0.6 kg with LY and gained 0.3 kg with GL (resulting in a treatment difference of  $-0.84$  kg,  $p < .01$ ). Weight loss was more common with LY than GL (57% vs 40%,  $p = .01$ ) and loss of  $\geq 5\%$  body weight was more frequent with LY than GL (5% vs 0%; respectively,  $p = .03$ ) with no correlation between baseline BMI and mean weight change. Higher insulin doses correlated with less weight loss with LY ( $p < .01$ ) and greater weight gain with GL ( $p < .01$ ). There was no correlation between hypoglycaemia rate and weight change with LY ( $p = .28$ ). In the T1D trial, patients lost 1.2 kg with LY and gained 0.7 kg with GL (resulting in a treatment difference of  $-1.9$  kg,  $p < .01$ ). Weight loss was more common during LY treatment (66% vs 40%,  $p < .01$ ) as was loss of  $\geq 5\%$  body weight (12% vs 1%;  $p < .01$ ) with no correlation between weight and baseline BMI or dose for either insulin. Prandial insulin dose decreased (0.23 U/kg/day to 0.19 U/kg/day) with LY and increased to 0.24 U/kg/day with GL (between-treatment  $p < .01$ ). More mild gastrointestinal (GI) adverse events were reported with LY, but LY-treated patients with GI events had less weight loss (0.84 kg) than those without (1.33 kg). There was no correlation between hypoglycaemia rate and weight change with LY ( $p = .65$ ).

**Conclusion:** Improved glycaemic control with long-acting basal insulin analogue LY is associated with weight loss that is not dependent on baseline BMI or rate of hypoglycaemic events.

## 919

**Lower glucose variability and hypoglycaemia measured by continuous glucose monitoring with novel long-acting insulin LY2605541 versus insulin glargine**4E.J. Bastyr<sup>1</sup>, R.M. Bergenstal<sup>2</sup>, J. Rosenstock<sup>3</sup>, M.J. Prince<sup>1</sup>, Y. Qu<sup>1</sup>, S.J. Jacober<sup>1</sup>;<sup>1</sup>Eli Lilly and Company, Indianapolis, <sup>2</sup>International Diabetes Center at Park Nicollet, Minneapolis, <sup>3</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA.

**Background and aims:** The basal insulin analogue LY2605541 (LY) is PE-Glylated insulin lispro designed to have a large hydrodynamic size which delays insulin absorption and reduces clearance, resulting in prolonged duration of action. Hypoglycaemia and glucose variability were assessed with continuous glucose monitoring (CGM) of interstitial glucose (IG) in a subset of patients with type 2 diabetes from a Phase 2, randomised, open-label, parallel study of LY (n=51) or insulin glargine (GL, n=25).

**Materials and methods:** CGM was conducted on 3 consecutive days (72–84 hrs) during the week before Week 0, 6, and 12 study visits, and IG intra-patient, intra- and inter-day standard deviations (SD) during nocturnal (2400–0600 hrs) and diurnal (0600–2400 hrs) periods were calculated to assess glucose variability. A hypoglycaemia episode was defined as IG  $\leq$  3.9 mmol/L and continued until IG  $>$  3.9 mmol/L for 15 min (or 3 time points), and all statistical comparisons were tested at 2-sided alpha = 0.1.

**Results:** At 12 weeks, LY-treated patients spent less time with IG below 3.9 mmol/L than GL-treated patients during the nocturnal period ( $11 \pm 5$  vs.  $38 \pm 13$  min,  $p=.024$ ) and during the 24-hr period ( $25 \pm 6$  vs.  $83 \pm 16$  min,  $p<.001$ ). Significantly fewer LY- than GL-treated patients experienced any hypoglycaemia (50.0% vs. 78.3%,  $p=.036$ ), including nocturnal hypoglycaemia (20.5% vs. 47.8%,  $p=.027$ ), based on CGM. At 12 weeks, both treatments resulted in similar mean glucose values, as indicated by the area under the IG curve, during the 24-hr period (LY: 11601 mmol/L•min; GL: 11286 mmol/L•min). LY-treated patients had significantly lower intra-day glucose SD at 12 weeks compared to GL-treated patients for both nocturnal ( $1.00 \pm 0.07$  vs.  $1.35 \pm 0.16$  mmol/L,  $p=.061$ ) and diurnal ( $2.03 \pm 0.10$  vs.  $2.50 \pm 0.18$  mmol/L,  $p=.039$ ) periods.

**Conclusion:** In conclusion, by CGM, LY treatment compared to GL resulted in: less time spent in hypoglycaemia, fewer patients experiencing hypoglycaemia, and lower intra-day glucose variability.

## 920

**Reduced nocturnal hypoglycaemia with insulin degludec as compared to insulin glargine: results of a 2-year randomised trial in type 2 diabetes**H.W. Rodbard<sup>1</sup>, B. Zinman<sup>2</sup>, B. Cariou<sup>3</sup>, A. Philis-Tsimikas<sup>4</sup>, Y. Handelsman<sup>5</sup>, T.V. Skjoth<sup>6</sup>, P.-L. Chu<sup>7</sup>, C. Mathieu<sup>8</sup>;<sup>1</sup>Endocrine and Metabolic Consultants, Rockville, USA, <sup>2</sup>Samuel Lunenfeld Research Institute, Mount Sinai Hospital, University of Toronto, Canada,<sup>3</sup>Department of Endocrinology, Nantes University Hospital, Nantes, France,<sup>4</sup>Scripps Whittier Diabetes Institute, La Jolla, USA, <sup>5</sup>Metabolic Institute of America, Tarzana, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>Novo Nordisk Inc., Princeton, USA, <sup>8</sup>UZ Gasthuisberg, KU Leuven, Belgium.

**Background and aims:** This 2-year (yr), open-label, treat-to-target, non-inferiority study compared the efficacy and safety of the new ultra-long-acting basal insulin degludec (IDeg) to glargine (IGlar), when used in combination with OADs in type 2 diabetes mellitus (T2DM).

**Materials and methods:** The study consisted of a 1-yr initial study period followed by a 1-yr extension, with subjects maintaining the randomisation treatment assignment throughout. Subjects were randomised 3:1 to IDeg or IGlar given s/c once daily in combination with metformin  $\pm$  DPP-4 inhibitor. Basal insulin was titrated to achieve pre-breakfast, plasma-corrected, self-monitored blood glucose targets of 3.9–4.9 mmol/L. Statistical analyses of glycaemic efficacy endpoints, hypoglycaemia, and body weight were performed following the intention-to-treat principle. HbA<sub>1c</sub> results from the extension trial set (ETS), including subjects receiving at least one dose of IDeg or IGlar in the extension period, are also presented. Data at the end of 2 yrs of treatment [EOT] are presented.

**Results:** Of 1030 subjects (mean age 59 yrs; diabetes duration 9.2 yrs; HbA<sub>1c</sub> 8.2%; fasting plasma glucose [FPG] 9.7 mmol/L), 725 entered the extension and 659 (IDeg: 505; IGlar: 154) completed 2 yrs of treatment. Mean observed

HbA<sub>1c</sub> reduction at EOT was similar between the two groups: 1.0% (IDeg) vs 1.1% (IGlar); estimated treatment difference [ETD] IDeg-IGlar: 0.12% [95%CI -0.01; 0.25],  $p=NS$ ; ETS: 1.1% vs 1.2%; ETD: 0.07% [-0.07; 0.22],  $p=NS$ . A similar proportion of subjects achieved HbA<sub>1c</sub>  $<$ 7% (IDeg: 47%; IGlar: 53%;  $p=NS$ ). Mean observed FPG reduction was greater with IDeg: 3.6 vs 3.2 mmol/L; ETD: -0.38 mmol/L [-0.70; -0.06];  $p=0.02$ . Rates of overall confirmed hypoglycaemia (PG  $<$  3.1 mmol/L or severe) were similar for the entire 2-yr period (1.72 [IDeg] vs 2.05 [IGlar] episodes/pt-yr; estimated rate ratio (ERR) IDeg/IGlar: 0.84 [0.68; 1.04];  $p=NS$ ). Severe hypoglycaemia was infrequent but significantly lower with IDeg (0.01 vs 0.02 episodes/pt-yr; ERR: 0.31 [0.11; 0.85];  $p=0.02$ ). Nocturnal confirmed hypoglycaemia rates were significantly 43% lower with IDeg (0.27 vs 0.46 episodes/pt-yr; ERR: 0.57 [0.40; 0.81];  $p<0.001$ ), indicating that treating 5.3 patients for 1 yr with IDeg will avoid 1 nocturnal confirmed hypoglycaemic episode. Mean daily basal insulin doses were similar at EOT (0.63 U/kg for IDeg and IGlar). Observed body weight increases (IDeg: 2.7 kg; IGlar: 2.4 kg) were similar, as were adverse event rates (3.6 vs 3.4 events/pt-yr).

**Conclusion:** When utilized as basal insulin in combination with OADs in T2DM over 2 yrs, degludec safely and effectively improves long-term glycaemic control with a lower risk of nocturnal and severe hypoglycaemia when compared to glargine.

## 921

**Insulin degludec is highly efficacious regardless of diabetes duration or body mass index: a cross-trial evaluation**L. Blonde<sup>1</sup>, L. Endahl<sup>2</sup>, N. Lassota<sup>2</sup>;<sup>1</sup>Ochsner Diabetes Research Unit, New Orleans, USA, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark.

**Background and aims:** Widely accepted treatment goals for antihyperglycaemic therapy include lowering HbA<sub>1c</sub> to levels of  $\leq$ 6.5% or  $<$ 7%. Not all patients are able to achieve these targets, for diverse reasons. We conducted a cross-trial evaluation to determine if certain baseline characteristics influence whether a patient achieves treatment goals with the new ultra-long-acting basal insulin, insulin degludec (IDeg).

**Materials and methods:** Three phase 3a trials, including previously insulin-naïve patients with type 2 diabetes (T2D) as well as patients with type 1 diabetes (T1D) on basal-bolus treatment, were used to assess whether certain baseline characteristics (HbA<sub>1c</sub>, known diabetes duration and BMI) differed between the entire IDeg-treated trial population and those individuals achieving HbA<sub>1c</sub>  $\leq$ 6.5% or  $<$ 7% with IDeg treatment. In trial A (trial 3668), a total of 228 patients with T2D previously insulin-naïve or receiving basal insulin treatment were given once-daily (OD) IDeg for 26 weeks. In trial B (trial 3582) and trial C (trial 3583), 744 and 472 previously insulin-treated patients with T2D and T1D, respectively, received IDeg OD for 52 weeks, with insulin aspart at mealtimes.

**Results:** The proportion of IDeg-treated patients achieving HbA<sub>1c</sub>  $\leq$ 6.5% or  $<$ 7% was 23% and 41%, respectively (trial A), 31% and 49%, respectively (trial B), and 24% and 40%, respectively (trial C). Mean baseline values (HbA<sub>1c</sub>, diabetes duration and BMI) varied across trials, reflecting the different patient populations being studied. In all three trials, patients achieving HbA<sub>1c</sub>  $\leq$ 6.5% or  $<$ 7% had a lower HbA<sub>1c</sub> at baseline compared with the entire population treated with IDeg (Table 1). Neither known duration of diabetes nor BMI were systematically different for patients achieving HbA<sub>1c</sub>  $\leq$ 6.5% or  $<$ 7% compared with the entire population.

**Conclusion:** This evaluation of patients with T2D or T1D suggests that neither diabetes duration nor BMI are factors that influence whether patients will achieve HbA<sub>1c</sub>  $\leq$ 6.5% or  $<$ 7.0% when initiating treatment with once-daily IDeg or switching to IDeg from another basal insulin. As expected, individuals achieving HbA<sub>1c</sub>  $\leq$ 6.5% or  $<$ 7% are characterised by a lower baseline HbA<sub>1c</sub>. Based on the above studies, the likelihood of a patient achieving HbA<sub>1c</sub> targets with once-daily IDeg is not influenced by diabetes duration or BMI at baseline, but by baseline HbA<sub>1c</sub>.

Table 1: Baseline HbA<sub>1c</sub>, but not diabetes duration or BMI, was associated with subjects reaching HbA<sub>1c</sub> targets across three randomised trials.

	HbA <sub>1c</sub> ≤6.5%	HbA <sub>1c</sub> <7%	All subjects
HbA <sub>1c</sub> (%)			
Trial A	7.8	7.9	8.4
Trial B	8.0	8.0	8.3
Trial C	6.8	7.0	7.7

### Pharmacokinetics (PK) of the novel, long-acting basal insulin LY2605541 in subjects with varying degrees of renal function

H. Linnebjerg, S.L. Choi, E.C.Q. Lam, K.F. Mace, T.S. Hodgson, V.P. Sinha; Eli Lilly and Company, Indianapolis, USA.

**Background and aims:** The basal insulin LY2605541 (LY) is PEGylated insulin lispro designed to have a large hydrodynamic size which delays insulin absorption and reduces clearance, resulting in prolonged duration of action. This Phase 1, multi-site, open-label study was designed to investigate the PK of LY in subjects with renal impairment.

**Materials and methods:** The PK of LY after a single subcutaneous dose (3 nmol/kg) was evaluated in 5 groups of subjects [Table]. Serial PK samples were collected up to 12 days post-dose. For subjects with end stage renal disease (ESRD), LY was given approximately 48 h before subjects resumed their normal dialysis schedule (2–4 hemodialysis sessions over the 12-day PK sampling period).

**Results:** The apparent clearance (CL/F) and half-life ( $t_{1/2}$ ) across the groups were not affected by renal function; the relationship between CL/F and the estimated creatinine clearance (CrCL) was not significant (slope=0.000863 [ $p=0.885$ ]). Dose-normalized  $C_{max}$  values ( $C_{max}/\text{Dose}$ ) in subjects with moderate and severe renal impairment were slightly lower compared to control subjects, but with similar overall LY serum exposure (dose-normalized  $AUC_{(0-\infty)}$  [ $AUC_{(0-\infty)}/\text{Dose}$ ]). Dialysis did not result in a significant LY elimination ( $\leq 25\%$ ) relative to the overall AUC in subjects with ESRD. LY was well tolerated in healthy subjects and those with renal impairment.

**Conclusion:** In conclusion, the PK properties of LY appear to be unaffected by renal impairment. Therefore no specific dose adjustment due to PK would be needed with increasing renal impairment.

	Estimated Creatinine Clearance (CrCL, mL/min)				
	Normal Function (>80)	Mild Impairment (51–80)	Moderate Impairment (30–50)	Severe Impairment (<30)	ESRD (Dialysis for >3 months)
Demographics [N or Mean (SD)]					
N (M/F)	12 (9/3)	8 (7/1)	8 (5/3)	9 (4/5)	9 (6/3)
Age (years)	45.5 (15.3)	68.9 (8.9)	61.0 (13.3)	61.8 (11.5)	44.4 (10.7)
Weight (kg)	81.3 (15.1)	84.5 (13.0)	73.7 (16.0)	66.7 (10.1)	79.9 (19.3)

## 923

### Insulin degludec has similar pharmacokinetic properties in subjects with renal impairment and subjects with normal renal function

H.L. Haahr<sup>1</sup>, G. Arold<sup>2</sup>, S.G. Böttcher<sup>3</sup>, M. Thrane<sup>4</sup>, I. Kiss<sup>5</sup>;

<sup>1</sup>Department of Insulin Clinical Pharmacology, Novo Nordisk A/S, Søborg, Denmark, <sup>2</sup>PRA International GmbH, Berlin, Germany, <sup>3</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>4</sup>Novo Nordisk A/S, Copenhagen, Denmark, <sup>5</sup>St Imre Teaching Hospital, Budapest, Hungary.

**Background and aims:** Insulin degludec (IDeg) is a new-generation basal insulin forming soluble multi-hexamers upon subcutaneous injection, resulting in a flat and stable ultra-long action profile. This open-label, parallel-group trial investigated the pharmacokinetic (PK) properties of IDeg in subjects with different grades of renal impairment and subjects with normal renal function (NRF) following single doses of 0.4 U/kg IDeg. In addition, the influence of haemodialysis on clearance of IDeg was investigated in end-stage renal disease (ESRD) subjects by administration of two single doses of IDeg, one before and one just after haemodialysis.

**Materials and methods:** A total of 30 subjects (mean age: 65.6 years; females/males: 15/15; mean BMI: 28.4 kg/m<sup>2</sup>) were allocated to one of five renal function groups ( $n=6$  per group): NRF, mild, moderate, severe renal impairment or ESRD.

**Results:** PK profiles of IDeg were similar for subjects with normal and impaired renal function. Renal impairment had no statistically significant effect on total exposure ( $AUC_{0-120h,SD}$ ), maximum concentration ( $C_{max,SD}$ ) or apparent clearance ( $CL/F_{SD}$ ) [Table 1]. PK profiles of IDeg for subjects with ESRD were similar irrespective of whether subjects received haemodialysis or not. Haemodialysis did not affect CL/FSD, and no unaltered IDeg was detected in dialysate samples collected during dialysis from subjects with ESRD.

**Conclusion:** The ultra-long PK properties of IDeg are preserved in subjects with renal impairment; renal impairment did not result in differences in the PK properties of IDeg compared to subjects with NRF. Haemodialysis did not affect the clearance of IDeg.

#### PK endpoints vs. creatinine clearance

	$AUC_{IDeg,0-120h,SD}$	$C_{max,IDeg,SD}$	$CL/F_{IDeg,SD}$
Estimated slope	-0.138	-0.171	0.129
95% CI	[-0.390; 0.113]	[-0.415; 0.073]	[-0.120; 0.378]
Statistical significance	NS	NS	NS

Estimated slope: a measure of correlation between creatinine clearance and PK endpoint; CI: confidence interval; NS: non-significant ( $p \geq 0.05$ ).

Renal impairment was classified based on creatinine clearance ( $CL_{CR}$ ) estimated by the Cockcroft & Gault formula, and subjects were grouped as: Normal ( $CL_{CR} > 80$  mL/min), mild ( $CL_{CR} > 50$ – $\leq 80$  mL/min), moderate ( $CL_{CR} > 30$ – $\leq 50$  mL/min), severe ( $CL_{CR} \leq 30$  mL/min or end-stage renal disease (ESRD)).

### Ultra-long pharmacokinetic properties of insulin degludec in younger adults are preserved in geriatric subjects with type 1 diabetes

S. Korsatko<sup>1</sup>, S. Deller<sup>1</sup>, J. Mader<sup>1</sup>, K. Glettl<sup>1</sup>, G. Köhler<sup>1</sup>, G. Bock<sup>1</sup>, M. Urschitz<sup>1</sup>, M. Wolf<sup>1</sup>, H. Hastrup-Nielsen<sup>2</sup>, F. Søndergaard<sup>3</sup>, H.L. Haahr<sup>2</sup>, T.R. Pieber<sup>1</sup>;

<sup>1</sup>Medical University of Graz, Austria, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>3</sup>Novo Nordisk A/S, Aalborg, Denmark.

**Background and aims:** Insulin degludec (IDeg) is an ultra-long-acting basal insulin that forms soluble multi-hexamers upon subcutaneous injection resulting in a depot from which IDeg is continuously and slowly absorbed into the circulation leading to a flat and stable glucose-lowering effect. This study investigated the pharmacokinetic (PK) and pharmacodynamic (PD) properties of IDeg in geriatric ( $\geq 65$  years) versus younger adult (18–35 years) subjects with type 1 diabetes (C-Peptide  $< 0.3$  nmol/L).

**Materials and methods:** This was a randomised, double-blind, two-period cross-over, multiple-dose study with 6 days of once-daily administration of 0.4 U/kg IDeg or 0.4 U/kg insulin glargine. Data are shown for IDeg only. Fourteen geriatric (mean age: 67.8 years; baseline HbA<sub>1c</sub>: 7.7%; BMI: 26.2 kg/

m<sup>2</sup>) and 13 younger adult (mean age: 27.1 years; baseline HbA<sub>1c</sub>: 7.8%; BMI: 24.4 kg/m<sup>2</sup>) subjects participated.

**Results:** The mean IDeg concentration-time profile at steady state (SS) was similar in geriatric and younger adult subjects. There was no statistically significant difference in total exposure (AUC<sub>IDeg,tau,SS</sub>) or maximum concentration (C<sub>max,IDeg,SS</sub>) of IDeg between geriatric and younger adults (Table 1), mean ratio [95% CI] C<sub>max,SS</sub>: 1.02 [0.74; 1.39]. The estimated terminal half-life was 25 hours. There was no statistically significant difference between age groups in total glucose-lowering effect of IDeg (AUC<sub>GIR,tau,SS</sub>) (Table 1).

**Conclusions:** The ultra-long pharmacokinetic properties of IDeg in younger adults were preserved in geriatric subjects. Total exposure was similar and there were no differences in the glucose-lowering effect of IDeg between geriatric and younger adult subjects.

	PK: AUC IDeg,<tau>,SS (pmol*h/L)	PD: AUC GIR,<tau>,SS (mg/kg)
Geriatric (least square mean)	85673	1923
Younger adult (least square mean)	82727	2457
Geriatric vs. younger adult Mean ratio [95% CI]	1.04 [0.73; 1.47]	0.78 [0.47; 1.31]

Table 1: Pair-wise comparison of IDeg PK/PD in geriatric vs younger adult subjects with type 1 diabetes

## 925

### Insulin degludec provides similar pharmacokinetic and pharmacodynamic responses in Black, White and Hispanic/Latino patients with type 2 diabetes

M. Hompesch<sup>1</sup>, L. Morrow<sup>1</sup>, E. Watkins<sup>1</sup>, C. Roepstorff<sup>2</sup>, H.F. Thomsen<sup>3</sup>, H.L. Haahr<sup>2</sup>;

<sup>1</sup>Profil Institute for Clinical Research, Inc, Chula Vista, USA, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>3</sup>Novo Nordisk A/S, Aalborg, Denmark.

**Background and aims:** Insulin degludec (IDeg) is a new-generation basal insulin that forms soluble multi-hexamers upon s.c. injection, resulting in an ultra-long and consistent action profile. This randomised, double-blind, two-period, cross-over trial investigated the pharmacokinetic and pharmacodynamic properties of IDeg at steady-state (SS).

**Materials and methods:** The trial included 63 insulin-treated patients (26 females and 37 males) with type 2 diabetes of different race and/or ethnicity (18 Black, 23 White, 22 Hispanic/Latino; mean age: 52 years, BMI: 32.4 kg/m<sup>2</sup>, HbA<sub>1c</sub>: 8.2%). Patients completed two 6-day treatment periods with 0.6 U/kg-day of IDeg or insulin detemir (IDet). At the end of each treatment period, a 24-hour euglycaemic glucose clamp was performed (Biostat; clamp blood glucose level 5.0 mmol/L).

**Results:** IDeg resulted in a flat and stable glucose-lowering effect extending beyond 24 hours in all patients across race/ethnic groups. The effect was evenly distributed between the first and second 12 hours in all groups (AUC<sub>GIR,0-12h,SS</sub>/AUC<sub>GIR,<tau>,SS</sub> ranging between 0.48 and 0.54). The total glucose-lowering effect of IDeg at SS (AUC<sub>GIR,<tau>,SS</sub>) was 1940, 1722, and 2286 mg/kg in Black, White, and Hispanic/Latino subjects, respectively. Pair-wise comparisons were not significantly different (mean difference [95% CI]: Black vs. Hispanic/Latino -346 [-1088; 396]; Black vs. White 218 [-551; 986]; Hispanic/Latino vs. White 564 [-168; 1295] mg/kg). Pair-wise comparisons of total IDeg exposure (AUC<sub>IDeg,<tau>,SS</sub>) were also similar between the three groups with mean ratios [95% CI] of: Black vs. Hispanic/Latino 1.13 [0.95; 1.34], Black vs. White 1.10 [0.91; 1.31], and Hispanic/Latino vs. White 0.97 [0.82; 1.16] pmol-hour/L. There was no significant difference in the race/ethnicity pattern between IDeg and IDet for AUC<sub>GIR,<tau>,SS</sub>, p=0.85 or AUC<sub>ins,<tau>,SS</sub>, p=0.58. IDeg was well tolerated and no safety issues were identified.

**Conclusion:** IDeg resulted in similar pharmacokinetic and pharmacodynamic responses across race and ethnicity in patients with type 2 diabetes. Thus, the ultra-long pharmacological properties of IDeg are preserved across race and ethnic groups. While insulin doses must be adjusted on an individual basis, this trial supports the notion that differences in the response to IDeg should not be anticipated based on differences in race or ethnicity between patients.

#### Local tolerability of insulin degludec is comparable to insulin glargine: a meta-analysis of trials in type 1 and type 2 diabetes

L.F. Meneghini<sup>1</sup>, P.-M. Schumm-Draeger<sup>2</sup>, S. Harris<sup>3</sup>, M.-A. Gall<sup>4</sup>, N. Lassota<sup>4</sup>, J.S. Christiansen<sup>5</sup>;

<sup>1</sup>University of Miami Miller School of Medicine, Miami, USA, <sup>2</sup>Academic Teaching Hospital Munich Bogenhausen, Munich, Germany, <sup>3</sup>University of Western Ontario, London, Canada, <sup>4</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>5</sup>Aarhus University Hospital, Aarhus, Denmark.

**Background and aims:** Injection site reactions may occur following subcutaneous (s.c.) insulin administration. Insulin degludec (IDeg) is a new basal insulin that forms a soluble depot of multi-hexamers after s.c. injection.

**Materials and methods:** Utilising patient level data, we examined via meta-analysis whether the number of injection site reactions with IDeg was different from insulin glargine (IGlar) in patients with type 1 diabetes (T1D) or type 2 diabetes (T2D). The analysis included 6 randomised, open-label, controlled, treat-to-target, phase 3a trials of 26 or 52 weeks' duration with once-daily dosing of IDeg (n=3060) and IGlar (n=1198) in T1D (2 trials) and T2D (4 trials). There were more subjects treated with IDeg than IGlar due to a number of trials having a 3:1 randomisation. The number of injection site reactions was analysed with a negative binomial regression model.

**Results:** Although lower observed rates of injection site reactions were seen with IDeg compared to IGlar in both T1D and T2D (basal-only therapy), the differences were not statistically significant (Table). A similar proportion of patients (T1D+T2D) reported injection site reactions with IDeg (3.6%) and IGlar (3.5%). For both IDeg and IGlar, injection site reactions were most commonly reported as injection site haematoma, injection site reaction (unspecific) and injection site pain. Two injection site reactions for IGlar were classified as severe adverse events. Few patients (0.1%) with IDeg or IGlar withdrew from the trials due to injection site reactions (IDeg: injection site haematoma, injection site pain; IGlar: injection site reaction [unspecified]).

**Conclusion:** This meta-analysis demonstrates good local tolerability of IDeg compared to IGlar following s.c. injection.

#### Injection site reaction analysis outcomes

	Number of patients (n)		Observed rate per 100 exposure-years		Estimated rate ratio IDeg/IGlar	
	IDeg	IGlar	IDeg	IGlar	Rate ratio	95% CI
T1D+T2D (pooled)	3060	1198	6.8	7.0	0.86	[0.57; 1.30]
T1D <sup>a</sup>						
801			5.3	6.7	N/A	N/A
315						
T2D	2259	883	7.4	7.1	0.91	[0.56; 1.48]

#### Risk factors to predict insulin requirement for optimum control of blood glucose after glucocorticoid administration in patients with autoimmune diseases

H. Morita, T. Ikeda, I. Mori, Y. Kitada, K.-I. Taguchi, N. Takahashi, K. Fujioka, M. Yamauchi, K. Kajita, T. Ishizuka;  
Department of General Internal Medicine, Gifu University Graduate School of Medicine, Japan.

**Background and aims:** Glucocorticoid treatment often induces insulin resistance and hyperglycemia. High dose of glucocorticoid or the pulse therapy are initially required to treat severe disturbance of organs. It is important to predict in advance insulin requirement for optimum control of hyperglycemia induced by glucocorticoid administration for treatment of various autoimmune diseases. We aimed to investigate risk factors and their cutoff values to predict insulin requirement after glucocorticoid administration.

**Materials and methods:** We retrospectively evaluated patients with autoimmune diseases who admitted to our department between 2004 and 2011 and were treated with glucocorticoid. They were newly administered more than 5 mg/day of prednisolone and continued for at least 4 weeks. Patients who had already used insulin before initiation of glucocorticoid therapy and were administered GLP-1 analogue instead of insulin after glucocorticoid treatment were excluded.

**Results:** A total of 147 patients (mean age, 58±19 years) were analyzed in the present study. Insulin, oral antihyperglycemic agents and diet therapy alone were needed to improve hyperglycemia in 26, 24 and 97 patients, respectively. A multiple logistic regression analysis revealed that risk factors of insulin requirement after glucocorticoid administration were higher fasting plasma glucose, larger initial dose (mg/body weight) of prednisolone, higher HbA1c and male. Receiver operating characteristic (ROC) analysis showed that cutoff values of HbA1c, fasting plasma glucose and initial dose of prednisolone were 99 mg/dl, 0.74 mg/kg/day, 6.7%, respectively. Area under the curve of the ROC curve in fasting plasma glucose (0.85) was higher than in HbA1c (0.80) or initial dose of prednisolone (0.74).

**Conclusion:** More than 99 mg/dl of fasting plasma glucose before glucocorticoid administration is most valuable predicting factor for insulin requirement after glucocorticoid treatment.

## 928

### Night time glucose variability in obese type 2 diabetes patients treated with NPH insulin at bedtime may be related to the size of the needle

M. Pawlowski<sup>1</sup>, M. Rutkowska<sup>1</sup>, E. Szymanska-Garbacz<sup>1</sup>, M. Saryusz-Wolska<sup>1</sup>, J. Loba<sup>1</sup>, P. Grzelak<sup>2</sup>, L. Stefanczyk<sup>2</sup>, L. Czupryniak<sup>1</sup>; <sup>1</sup>Diabetologia, <sup>2</sup>Radiology, Medical University of Lodz, Poland.

**Background and aims:** In a large group of type 2 diabetes patients NPH insulin given at bedtime fails to control fasting blood glucose, even if a dose of the insulin is increased substantially. This problem is frequently encountered in obese subjects, in whom insulin absorption from subcutaneous tissue might be severely impaired and may depend on depth of the injection i.e. on the needle length. The effect of needle length on blood glucose control is poorly studied. The aim of this study was to assess the effect of using two various needle sizes on blood glucose excursions after NPH insulin dose administration.

**Materials and methods:** We studied 19 obese subjects (mean [±SD] age 62.3±5.0 years, 11 women, BMI 34.3±4.1 kg/m<sup>2</sup>), with long lasting type 2 diabetes (diabetes duration 14.3±4.2 years) and inadequate control of disease (HbA1c 8.6±1.1%). All subjects were treated with short acting insulin before meals and high dose of NPH insulin (46±11 IU) at bedtime. Subcutaneous fat tissue thickness assessed by ultrasound scanning was 2.1±0.6 cm. Glucose excursions were measured with the Continuous Glucose Monitoring System (CGMS; iPRO2, Medtronic, Minneapolis, USA) used consecutively for 5 days (4 nights), from Monday to Friday. For the first two days patients used 6 mm needle, and for the following two days they used 12.7 mm one. Insulin NPH was injected at the same site in the abdominal area. We compared fasting blood glucose (FBG), calculated average glucose (AG) and the total area under the curve (AUC) of glucose excursions during the night (0.00–6.00 am); glycemic variability coefficients were also calculated.

**Results:** Injecting NPH insulin with a 12.7 mm needle was associated with lower glycemia than when 6 mm needle was used: FBG was 134±16 vs 145±25 mg/dl (p=0.02), and AG 111.1±14.1 vs 133.8±32.7mg/dl (p=0.04), respectively. There was a trend for the AUC to be lower when 12.7 rather than 6 mm needle was used (7911±724 vs 9732±1641, p=0.04). Coefficient of variation was 11.1±6 when a short needle was used and 12.6±6.1 with a long one (p=0.37).

**Conclusion:** Poorly controlled obese type 2 diabetes patients may benefit from using longer needles for insulin NPH injections as it may result in the reduction of fasting blood glucose. Establishing whether this effect will be long lasting and eventually may lead to a significant HbA1c decrease requires further prospective studies.

## 929

### Efficacy of needle-free jet injection for the administration of rapid-acting insulin analogues is independent of the body-mass index

E.E.C. Engwerda<sup>1</sup>, E.J. Abbink<sup>2</sup>, C.J. Tack<sup>1</sup>, B.E. de Galan<sup>1</sup>; <sup>1</sup>General Internal Medicine 463, <sup>2</sup>Clinical Research Centre Nijmegen, Radboud University Nijmegen Medical Centre, Netherlands.

**Background and aims:** We previously showed that administration of rapid-acting insulin analogues by jet injection reduced the time to peak plasma insulin levels and the time to maximal insulin action by ~50%, when compared to conventional insulin injection by insulin pen. The current analysis was conducted to assess whether and to what extent body-mass index (BMI) affected the rate of insulin absorption and glucose-lowering action, when administered by jet injection or conventional insulin pen.

**Materials and methods:** Euglycaemic glucose clamps were performed in 18 healthy volunteers (BMI range, 18 to 28 kg/m<sup>2</sup>) after subcutaneous administration of 0.2 U/kg body weight of insulin aspart, either by jet injection or conventional pen, using a randomised, double-blind, double-dummy, crossover study design. The times to maximal plasma insulin level (T-INS<sub>max</sub>) and maximal glucose infusion rate (GIR) needed to maintain euglycemia (T-GIR<sub>max</sub>) were analysed in subgroups defined by BMI below the median of 23.6 kg/m<sup>2</sup> (BMI-low) or BMI above the median (BMI-high).

**Results:** After conventional insulin injection, T-INS<sub>max</sub> was 49±3 minutes in BMI-low versus 80±10 minutes in BMI-high (P=0.008), and T-GIR<sub>max</sub> was 77±10 in BMI-low versus 134±15 minutes in BMI-high (P=0.006). After jet injection, BMI-low and BMI-high subgroups did not differ with respect to T-INS<sub>max</sub> (29±4 versus 32±5 minutes, P=0.59) or T-GIR<sub>max</sub> (48±4 versus 54±4 minutes, P=0.31). In continuous analyses, BMI was significantly correlated to T-INS<sub>max</sub> (R=0.58, P=0.012) and T-GIR<sub>max</sub> (R=0.56, P=0.017) after conventional insulin administration, but not after jet injection (R=0.059 and 0.135, respectively, P both >0.5). As a consequence, the time-reducing benefit of using jet rather than conventional injection for insulin administration was greater in the BMI-high than in the BMI-low subgroup for both T-INS<sub>max</sub> (-48±9 versus -20±5 minutes, P=0.018) and T-GIR<sub>max</sub> (-80±16 versus -29±10 minutes, P=0.018).

**Conclusion:** BMI significantly affects the rate of absorption and action of aspart insulin when injected by conventional pen, but not when injected by jet injection. Therefore, using a jet injector for administration of rapid-acting insulin analogues may especially benefit subjects with higher BMI.

### Clinical test of fuzzy logic controller (FLC) in a closed loop artificial pancreas

R. Mauseth<sup>1</sup>, D. Matheson<sup>1</sup>, R. Kircher<sup>1</sup>, J. Bollyky<sup>2</sup>, C. Greenbaum<sup>2</sup>;

<sup>1</sup>Dose Safety, Inc., Redmond, <sup>2</sup>Benaroya Research Institute, Seattle, USA.

**Background and aims:** To evaluate the effectiveness of a fully automated system using a FLC in a 24-hr clinical research center setting. We wished to determine whether this system could (1) correct elevated blood glucose (BG), (2) control the fasting state and diurnal variation, (3) control the glycemic response to a small meal (30 gms CHO) and (4) control the glycemic response to a larger meal (60 gms CHO). Prior to the study, in silico testing was performed and the dosing aggressiveness parameter was established. Hypoglycemia avoidance was the primary focus and blood sugar control was secondary for this study, our first fully automated, closed loop human trial.

**Materials and methods:** A FLC was used to direct insulin delivery to adult type 1 patients. We used the Artificial Pancreas System developed by UC Santa Barbara and Sansum Diabetes Research Institute, an OmniPod pump and Dexcom Seven Plus sensors. There was no pre-meal priming boluses, nurse or physician data entry or modifications. The controller algorithm was initialized using only the patient's Total Daily Insulin. The controller automatically commanded the OmniPod pump on a five-minute cycle time.

**Results:** 8 adult subjects (4 men, 4 women, age 18–35 years, mean 23.6, A1c 6.4–8.6%, mean 7.7%) completed the overnight portion of the study. Table 1 shows the endpoint values for the midnight to 8am period. Two patients (number 1 and 4) did not complete the entire study due to technical issues. Procedural adjustments were made and no further problems occurred with the final six patients.

**Conclusion:** These preliminary data indicate that a FLC, initialized using only the patient's total daily insulin, may provide effective closed loop regu-

lation of blood glucose and reduce the risk of nocturnal hypoglycemia in a clinical setting for adults with type 1 diabetes.

Table 1: Midnight - 8am Results

Endpoint	Midnight-8am
Max blood glucose (mg/dL)	195 mg/dL
Min blood glucose (mg/dL)	95 mg/dL
Mean blood glucose	135 mg/dL
Percent time < 70 mg/dL	0.5%
Percent time > 200 mg/dL	4.0%
Percent time 70-200 mg/dL	95.6%
Percent time > 180 mg/dL	7.5%
Percent time in 70-180 mg/dL	92.0%
Percent time > 144 mg/dL	36.0%
Percent time in 70-144 mg/dL	63.5%

### Lowering blood glucose with continuous intravenous insulin infusion may have effect on QT interval

E. Szymanska-Garbacz, M. Saryusz-Wolska, M. Pawlowski, J. Loba, L. Czupryniak;  
Internal Medicine and Diabetology Department, Medical University of Lodz, Poland.

**Background and aims:** Poorly controlled type 1 diabetes patients are occasionally hospitalized and treated with continuous intravenous insulin infusion (CIVII), which is associated with a significant risk of hypoglycemia, an acknowledged risk factor for cardiac arrhythmias. The aim of the study was to assess heart rhythm during CIVII.

**Materials and methods:** The study group comprised 15 type 1 diabetes subjects (mean [±SD] age 32.6±10.7 years, diabetes duration 7.8±6.5 years, BMI 23.1±2.2 kg/m<sup>2</sup>, HbA1c 10.0±2.3%, pH 7.419±0.08, K<sup>+</sup> 4.34±0.39 mmol/l) without any heart disease or macrovascular complications or autonomic neuropathy, using no QT-affecting medications. CIVII consisted of basal insulin infusion and three 90-min mealtime boluses per day. Capillary blood glucose was measured every 60-90 min, and the CIVII rate was adjusted accordingly so as to achieve near normoglycemia. In all subjects 24-hour ECG monitoring was performed during the second day of CIVII.

**Results:** Mean blood glucose during CIVII was 174±51 mg/dl (range 28-432 mg/dl). No clinically significant abnormalities in ECG monitoring were noted. Mean QT interval was 422±14 ms. However, in the whole group there was a statistically significant correlation between QT interval during minimum and maximum blood glucose and these blood glucose values ( $r=-0.42$ ,  $p<0.05$ , Fig. 1). In addition, more insulin resistant subjects showed tendency to have longer QT interval ( $r=0.25$ ;  $p=0.06$ ).

**Conclusion:** In conclusion, using CIVII in otherwise healthy type 1 diabetes subjects may affect electrophysiological processes in the myocardium. This mode of treatment should be used with caution even in patients without cardiovascular disease.

Fig. 1. The correlation between QT interval during minimum and maximum blood glucose and these blood glucose values during CIVII (two blood glucose values per each patient).

## 932

### Effect of intraperitoneal insulin administration on IGF-1 concentrations in type 1 diabetes

P.R. van Dijk<sup>1</sup>, S.J.J. Logtenberg<sup>2</sup>, N. Kleefstra<sup>1,2</sup>, K.H. Groenier<sup>1</sup>, H.J.G. Bilo<sup>1,2</sup>, H.J. Arnqvist<sup>3</sup>;

<sup>1</sup>Diabetes centre, Isala Clinics, Zwolle, Netherlands, <sup>2</sup>Internal Medicine, University Medical Center Groningen, Netherlands, <sup>3</sup>Diabetes Research Centre, Linköping University, Sweden.

**Background and aims:** Insulin-like growth factor-1 (IGF-1) and insulin genes are part of the same family. In patients with type 1 diabetes, low IGF-1 concentrations and high levels of IGF binding protein-1 (IGFBP-1) have been reported. This may affect atherosclerotic processes and diabetic vascular lesions. It has been suggested that the low circulating IGF-1 and high IGFBP-1 is partly due to low insulin levels in the portal vein. The aim of this study is to investigate the effects of intraperitoneal (IP) administered insulin as compared to subcutaneous (SC) insulin on IGF-1 and IGFBP-1 levels.

**Materials and methods:** Open-label, randomized controlled cross-over trial. After a 3-month qualification phase, patients were randomized to receive either 6 months continuous intraperitoneal insulin infusion (CIPII) through an implantable pump (MIP 2007C, Medtronic) followed by 6 months SC insulin or vice versa with a washout phase in between. General linear models were used to test for differences in HbA1c values, taking the order of the two treatments into account. Due to missing values, linear mixed models were used for IGF-1 and IGFBP-1. Correlation between differences in IGF-1 and total daily insulin dose was calculated using Spearman's rho.

**Results:** Twenty-three patients (43.4% male) were included with a mean (±SD) age of 43.1 ± 12.0 years, diabetes duration of 22.1 ± 10.9 years and HbA1c of 8.6 ± 1.1 %. Mean IGF-1 concentrations at the start of the SC and IP insulin phase were available for 21 and 22 patients, respectively; 75.8 (23.3) ng/ml and 81.1 (30.1) ng/ml. After randomization, groups were comparable regarding clinical characteristics. After 3 and 6 months the IGF-1 levels with SC insulin were 72.1 (25.5) ng/ml and 76.0 (25.1) ng/ml compared to 97.2 (39.9) ng/ml and 89.0 (37.5) ng/ml with IP insulin. The change in mean IGF-1 concentration during CIPII was 12.3 ng/ml (95% confidence interval (CI) 1.4, 23.2 ng/ml;  $p=0.03$ ) and 0.7 ng/ml (95% CI -10.0, 11.5 ng/ml;  $p=0.88$ ) during SC insulin. Taking the effect of treatment order into account, the estimated increase of IGF-1 was 11.6 ng/ml (95% CI -3.3, 26.5 ng/ml;  $p=0.12$ ) with CIPII compared to SC insulin. In addition, the IGFBP-1 concentrations decreased with -138.4 ng/ml (95% CI -206.7, -70.1 ng/ml;  $p<0.001$ ) with CIPII. HbA1c improved -0.76% (95% CI -1.41, -0.11) in favor of IP insulin. There was a non-significant negative association between the mean difference in insulin dose and IGF1 level during IP treatment ( $r=-0.038$ ,  $p=0.87$ ).

**Conclusion:** During CIPII treatment there was a decrease in IGFBP-1 and a non-significant increase in IGF-1 compared to the SC insulin phase. Taken together, the findings in the current study support the hypothesis, but do not provide definite answers to the question whether IP insulin compared to SC insulin has beneficial effects on the IGF-1 system in type 1 diabetes.

Clinical Trial Registration Number: NCT00286962

## 933

**Comparison of glycaemic response to typical foods of the mediterranean diet using different types of insulin bolus in patients with type 1 diabetes treated with insulin pump**S. Murillo<sup>1</sup>, L. Brugnara<sup>1</sup>, E. Roura<sup>2</sup>, A. Novials<sup>1</sup>;<sup>1</sup>CIBERDEM - IDIBAPS, Hospital Clinic, Barcelona, <sup>2</sup>ALICIA foundation, St Fruitós de Bages, Spain.

**Background and aims:** The glycaemic index of foods explains the effects of certain foods on blood glucose during the 2 hours after ingestion. However, some foods have a delayed absorption and, in these cases, the application of extended or multi-wave insulin boluses could be more effective in controlling postprandial glycaemia than traditional normal boluses. The aim of this study was to analyze the postprandial blood glucose effects after the ingestion of 4 typical menus in the Mediterranean diet, comparing the results obtained by applying 3 types of preprandial insulin boluses.

**Materials and methods:** 36 individuals with T1D over 18 years of age, and using insulin pump therapy, were included in the study. The dinner menus included ham and cheese pizza, seafood paella, cured ham sandwich and barley casserole. All menus contained the same amount of carbohydrates (60.5±1.2g) and similar total energy values (664.7±58.9kcal). For three non-consecutive days, individuals included in the study had the same menu for dinner, using the same dose of insulin as a bolus (previously calculated using each subject's own particular ratio insulin / carbohydrates ratio), but applying a Normal bolus, an Extended bolus to 4 hours or a Multi-wave bolus (50% normal and 50% extended to 4 hours) on each day of the study. Postprandial blood glucose was monitored by a continuous glucose sensor (DexCom 7Plus) and we monitored levels of physical activity by an activity sensor (Armband of Sensewear). We evaluated the area under the curve (AUC), expressed as mg/dlx8hours, and obtained within 8 hours after the dinner, for the same menu. Statistical analysis was performed using Student's *t*-test. The *p*-values < 0.05 were considered to be significant.

**Results:** Pizza: AUC values using Normal Bolus (390.5±162.2) were lower than when using the Extended (539.3±181.4;ns) or Multi-wave (460.7±217.7;ns) bolus. There was an increased number of hypoglycaemic events using the Normal bolus (33%) than with a Multi-wave (11%) or Expanded (11%) bolus. In a later study, we performed a test with 9 individuals who ate only pizza dough (without cheese or ham) using a Normal bolus. AUC values were lower (172.0±57.7) in comparison with full pizza (390.5±162.2; *p*<0.05). Seafood paella: Normal bolus produces less AUC (198.5±140.9) than Extended (469.4±97.8; *p*<0.05) or Multi-wave (348.7±152.0;ns) bolus. Sandwich: Normal Bolus has a lower AUC (181.6±107.1) than the Extended bolus (495.0±183.3, *p*<0.05) or the Multi-wave bolus (393.0±195.0, *p*<0.05). Barley casserole: Normal bolus caused hypoglycaemia in 6 of the 9 subjects studied. Extended bolus had a higher but, not significant, AUC (317.7±198.8) than Multi-wave bolus (210.0±16.9;ns).

**Conclusion:** Normal bolus is effective for those menus based on high-glycaemic index foods, such as sandwiches or seafood paella. For the paella, having a long cooking time (15 minutes), behaves as fast-food absorption, despite the moderate glycaemic index of rice. In contrast, Multi-wave bolus seems advisable for a slow-digesting food, like pizza or barley, since Normal bolus increases the frequency of hypoglycaemic events.

## PS 076 Initiation of insulin therapy

## 934

**The effect of short-term continuous intravenous insulin infusion on long-term metabolic control in obese patients with type 2 diabetes**

M. Rutkowska, M. Pawlowski, J. Loba, L. Czupryniak;

Internal Medicine and Diabetology Department, Medical University of Lodz, Poland.

**Background and aims:** In a large group of obese type 2 diabetes achieving good metabolic control is extremely difficult, despite using all treatment options available in the outpatient setting (i.e. intensive education, intensive high-dose insulin treatment combined with oral agents administration). These patients may be treated with continuous intravenous insulin infusion (CIVII) in hospital as this mode of treatment improves blood glucose rapidly and is believed to counteract glucose toxicity. However, the long term effect of this procedure on metabolic control of diabetes is unknown. We conducted the study to assess the effect of short term CIVII on long term glucose control in obese subjects with type 2 diabetes.

**Materials and methods:** The study group comprised 36 type 2 diabetes patients treated with insulin (23 women and 13 men, mean age [±SD] 59.9 ± 7.7 years, diabetes duration 6.3 ± 3.0 years, body weight 92.9 ± 19.1 kg, BMI 33.5 ± 5.8 kg/m<sup>2</sup>, HbA1c 9.7 ± 1.8 %). In all subjects body weight, BMI, waist-to-hip ratio (WHR), blood pressure, fasting plasma triglycerides, total cholesterol, LDL- and HDL-cholesterol, and HbA1c levels were measured before and 6 months after CIVII. CIVII was applied for at least 72 hours, it consisted of basal insulin infusion and three 90-min insulin boluses per day administered at the meal time. Capillary blood glucose was measured every 90-120 min throughout the day and night. Hypoglycemia was diagnosed if capillary blood glucose was <60 mg/dl or when CIVII was stopped due to the symptoms of hypoglycemia. During the study period the subjects who used oral antidiabetic medication maintained it at stable doses. The controls were 24 type 2 diabetes patients (mean age 61.3 ± 7.2 years, BMI 32.8 ± 5.1 kg/m<sup>2</sup>, HbA1c 9.4 ± 1.6 %), who were subject to standard outpatient care and in whom the same parameters as in the study group were examined at baseline and after 6-month period.

**Results:** In obese type 2 patients 6 months after CIVII treatment HbA1c decreased significantly to 8.8 ± 1.6% (*p*<0.05), however no improvement in body weight, WHR, blood pressure or plasma lipid parameters was noted. Shortly after CIVII daily insulin dose was significantly reduced (from 64.5 ± 24.6 at baseline to 50.7 ± 10.8 IU/day on discharge from the hospital, *p*<0.05), yet 6 months later it was similar to the baseline insulin requirement. In the control subjects no statistically significant changes in analyzed parameters were found during the study period.

**Conclusion:** In patients with type 2 diabetes with poor metabolic control CIVII results in significant improvement of long-term glucose control, without exerting effect on other metabolic parameters.

## 935

**Comparison of three titration algorithms for the initiation of basal insulin in patients with type 2 diabetes mellitus**L. Aurand<sup>1</sup>, G. Dailey<sup>2</sup>, J. Stewart<sup>3</sup>, B. Ameer<sup>4</sup>, R. Zhou<sup>5</sup>;<sup>1</sup>Sanofi-aventis U.S., Bridgewater, USA, <sup>2</sup>Scripps Clinic, La Jolla, USA,<sup>3</sup>Sanofi-Aventis Canada, Quebec, Canada, <sup>4</sup>Robert Wood Johnson Medical School, New Brunswick, USA, <sup>5</sup>Medpace, Cincinnati, USA.

**Background and aims:** On initiation of basal insulin therapy in patients with type 2 diabetes mellitus (T2DM), the dose is titrated until target fasting plasma glucose (FPG) is achieved. Many different basal insulin titration algorithms have been studied and it may be difficult for health care providers to choose one. This pooled analysis of patient-level data compared endpoints from studies using different treatment algorithms for the initiation and intensification of insulin glargine, in insulin-naïve patients with T2DM.

**Materials and methods:** Data were pooled from 8 randomized controlled trials that added insulin glargine to oral antidiabetic drugs (OADs) at a 10 U starting dose, using 3 different treatment algorithms. Differences in the baseline characteristics between algorithms were analyzed by *t*-test or  $\chi^2$  test where appropriate. Change from baseline endpoint variables were analyzed using a mixed model with algorithm as a factor and corresponding baseline measurement as covariate.

**Results:** Algorithm 1 ( $n = 163$ ; mean age 57 years; 66% men) required 1 U daily when FPG was above target; algorithm 2 ( $n = 117$ ; mean age 59 years; 62% men) required 2 U every 3 days when FPG was above target; and algorithm 3 ( $n = 1100$ ; mean age 57 years; 54% men) used a treat-to-target approach, generally increasing 2–8 U weekly based on 2-day mean FPG levels. At baseline, there were differences in FPG and  $HbA_{1c}$  levels between the cohorts (Table). After adjusting for the baseline measurements, algorithm 2 had a significantly greater change in  $HbA_{1c}$  than did 1 (Table). Algorithm 3 tended towards more confirmed hypoglycemia, and in all groups the incidence of severe hypoglycemia was low, ranging 0–1.5% (Table). However, comparison of severe hypoglycemia between groups was limited due to few events. Final insulin doses were 0.43 U/kg, 0.60 U/kg, and 0.44 U/kg for algorithms 1, 2, and 3, respectively; with significantly higher doses for algorithm 2 vs 1 and 3, although when insulin dose at endpoint was corrected for  $HbA_{1c}$  change, doses were only significantly different for algorithm 2 vs 3. Baseline OAD therapy use differed across groups; those receiving metformin and a sulfonylurea (SU) made up 51%, 70% and 71% of algorithms 1, 2 and 3 respectively. When patients taking only metformin plus sulfonylurea at baseline were analyzed the results were comparable to those found in the whole population (Table).

**Conclusion:** These data suggest that simpler titration algorithms (1 and 2) achieved similar glycemic control vs more complex algorithms (3), with less confirmed hypoglycemia. These data may assist the choice of algorithm for initiation and intensification of basal insulin in patients with T2DM, but need validation with a randomized controlled trial.

Table: Baseline values and outcomes for 3 titration algorithms.

	Total Population ( $n=1380$ )			Metformin and SU ( $n=948$ )		
	Algo- rithm 1	Algo- rithm 2	Algo- rithm 3	Algo- rithm 1	Algo- rithm 2	Algo- rithm 3

### Real-world comparative outcomes study in US patients with type 2 diabetes initiating basal insulin analogues

K.L. Davis<sup>1</sup>, J.L. Meyers<sup>1</sup>, M. Tangirala<sup>2</sup>, W. Wei<sup>2</sup>;

<sup>1</sup>RTI Health Solutions, Research Triangle Park, <sup>2</sup>Sanofi-Aventis U.S., Bridgewater, USA.

**Background and aims:** Currently, there is a paucity of real-world comparative effectiveness data among patients with type 2 diabetes mellitus (T2DM) initiating basal insulin analogs. Using a database of anonymized electronic medical records (EMR), this study compared outcomes among real-world US T2DM patients initiating insulin therapy with either insulin glargine (GLA) or insulin detemir (DET).

**Materials and methods:** Using the General Electric Centricity EMR database, a retrospective comparative analysis was conducted among T2DM patients who were  $\geq 18$  years old, initiated GLA or DET between January 1, 2006, and December 31, 2010, had EMR activity for  $\geq 6$  months prior to (baseline) and  $\geq 12$  months after (follow-up) GLA or DET initiation, and were previously or currently treated with only oral antidiabetic drugs (OADs) and/or a glucagon-like peptide-1 (GLP-1) analogue. To limit selection bias, each DET patient was matched with up to 5 GLA patients based on their baseline demographic and clinical characteristics. Study endpoints included

treatment persistence,  $HbA_{1c}$ , body weight, BMI, and chart-recorded hypoglycemia rate during the 12 month follow-up.

**Results:** A total of 6,620 (GLA: 5,473, DET: 1,147) patients were matched and analysed from 11,727 (GLA: 10,580, DET: 1,147) eligible patients. Patients were well balanced on the observed baseline characteristics (mean, GLA vs DET: male [%], 49.0 vs 48.5; age [years] 57.8 vs 57.4;  $HbA_{1c}$  [%], 9.4 vs 9.4; body weight [kg], 102.1 vs 102.6; BMI [kg/m<sup>2</sup>] 35.7 vs 35.9). Other well balanced baseline characteristics were geography, payer type, provider specialty, year of insulin initiation, prior chronic medication use and comorbidities. During the 1-year follow-up, significantly fewer patients were still taking DET at the end of 6, 9, and 12 months post-initiation (Figure). Prevalence of hypoglycemia was similar during the 1-year follow-up (2.87 vs 3.23%,  $P = 0.5143$ ). At the end of follow-up, the GLA cohort had significantly lower  $HbA_{1c}$  than the DET cohort (8.24 vs 8.37%,  $P = 0.0353$ ), the change in  $HbA_{1c}$  from baseline was also greater in the GLA cohort (−1.11 vs −0.96%,  $P = 0.0479$ ). There was no significant difference in weight (102.8 vs 102.8 kg,  $P = 0.9538$ ) or weight change from baseline (0.65 vs 0.40 kg,  $P = 0.3116$ ). BMI was also similar at the end of 1 year follow-up (35.92 vs 36.03 kg/m<sup>2</sup>,  $P = 0.6848$ ).

**Conclusion:** This EMR study of almost 7,000 matched US T2DM patients initiating basal insulin analogs suggested that, in the real-world setting, initiating GLA, as compared to DET, may be associated with greater persistence and better glycemic outcomes with similar hypoglycemia incidence and weight/BMI change.

### The effects of early basal insulin treatment on inflammation and endothelium-related biomarkers in patients with type 2 diabetes

U. Ünlütürk<sup>1</sup>, A.S. Kesikli<sup>2</sup>, C. Ates<sup>3</sup>, G. Günaydin<sup>2</sup>, A.R. Uysal<sup>1</sup>, R. Emral<sup>1</sup>;

<sup>1</sup>Endocrinology and Metabolism, Ankara University School of Medicine, <sup>2</sup>Basic Oncology, Hacettepe University Institute of Oncology, <sup>3</sup>Biostatistics, Ankara University School of Medicine, Turkey.

**Background and aims:** In type 2 diabetes mellitus (T2DM), there is a lack of comparison of different treatment alternatives, especially in terms of pleiotropic effects such as the effects on endothelial functions, coagulation status and inflammation. This study was mainly prepared to analyze the effects of early basal insulin versus sulfonylurea treatment on endothelial injury, coagulation status and inflammation-related biomarkers in patients with T2DM.

**Materials and methods:** A total of 43 patients with T2DM, 16 in the insulin Detemir treatment arm and 27 in the gliclazide-MR arm were included. The study protocol is summarized in Figure 1. Plasma levels of soluble markers of endothelial activation or damage, such as intercellular cell adhesion molecule-1 (sICAM-1), vascular cell adhesion molecule-1, E-selectin and P-selectin; markers of inflammation like monocyte chemoattractant protein-1 and interleukin-6, and markers to determine the tendency towards coagulation, like tissue plasminogen activator and plasminogen activator inhibitor-1 levels were investigated using commercially available ELISA kits.

**Results:** Both treatment protocols were equally effective in controlling blood glucose. sICAM-1 levels were observed to decrease significantly between the basal and 6<sup>th</sup> month follow-up measurements in the early insulin treatment arm. Moreover, sE-selectin levels were demonstrated to decrease between the basal and 3<sup>rd</sup> month follow-up measurements only in the insulin Detemir arm. Although sP-selectin levels were demonstrated to increase sig-

nificantly in both patient groups, the increment in the insulin Detemir arm was significant only between the 3<sup>rd</sup> and 6<sup>th</sup> month follow-up measurements, showing the effect of the addition of sulfonylurea to the treatment protocol. Levels of other markers were indifferent between the two treatment groups. **Conclusion:** These results suggest that early basal insulin treatment might be a promising approach in preventing late complications associated with T2DM, through inhibiting endothelial activation and damage.

### Reduction in HbA<sub>1c</sub> and hypoglycaemia rates with insulin glargine vs NPH in treatment-naïve patients with type 2 diabetes stratified by BMI: pooled analysis of 6 clinical trials

G.B. Bolli<sup>1</sup>, F. Porcellati<sup>1</sup>, J. Lin<sup>2</sup>, A. Cali<sup>3</sup>, E. Wang<sup>4</sup>, M.-P. Dain<sup>3</sup>, P. Lucidi<sup>1</sup>, C.G. Fanelli<sup>1</sup>

<sup>1</sup>University of Perugia, Italy, <sup>2</sup>Novosys Health, Flemington, USA, <sup>3</sup>Sanofi, Paris, France, <sup>4</sup>Sanofi, Bridgewater, USA.

**Background and aims:** Insulin glargine is as efficacious as NPH insulin but is associated with lower incidence of hypoglycaemia. The aims of this pooled analysis were to compare efficacy and safety of glargine and NPH in treatment-naïve patients with type 2 diabetes (T2DM). Additional analysis was conducted to determine HbA<sub>1c</sub> reduction and incidence of severe and severe nocturnal hypoglycaemia based on BMI strata (< 30 kg/m<sup>2</sup> and ≥ 30 kg/m<sup>2</sup>) for patients using insulin glargine or NPH.

**Materials and methods:** Intent-to-treat populations were pooled from 6 randomised clinical trials of subjects with T2DM begun on insulin for 24 to 36 weeks. HbA<sub>1c</sub> and BMI were measured at baseline and endpoint. Severe and severe nocturnal hypoglycaemia were recorded.

**Results:** A total of 2600 subjects received either glargine (n = 1385) or NPH (n = 1215). There were no differences in baseline characteristics between groups, and 35% vs 34% had BMI ≥ 30 kg/m<sup>2</sup> in the glargine and NPH groups, respectively. At endpoint, in the overall analysis, HbA<sub>1c</sub> levels fell from mean (SD) 9.0 (1.0) % in both to 7.6 (1.2) % in the glargine group and 7.7 (1.2) % in the NPH group. The change from baseline was similar in both groups (-1.3 [1.2] %). In patients with BMI < 30 kg/m<sup>2</sup>, glargine use was associated with a significant reduction in HbA<sub>1c</sub> compared with NPH (-1.29 vs -1.14%, *P* = 0.008). The reduction in HbA<sub>1c</sub> was similar for both treatments in patients with BMI ≥ 30 kg/m<sup>2</sup>. Fewer subjects on glargine compared with NPH experienced severe hypoglycaemia, both overall and in the BMI < 30 kg/m<sup>2</sup> subgroup (Overall: 2.0% vs 3.2%; *P* = 0.04; BMI < 30 kg/m<sup>2</sup>: 2.2% vs 3.9%, *P* = 0.04, respectively). Treatment with glargine was associated with lower incidence of severe nocturnal hypoglycaemia compared with NPH overall and in 2 BMI subgroups (Overall: 0.7% vs 2.1%; *P* = 0.002; BMI < 30 kg/m<sup>2</sup>: 1.0% vs 2.4%, *P* = 0.02; BMI ≥ 30 kg/m<sup>2</sup>: 0.2% vs 1.7%, *P* = 0.01, respectively).

**Conclusion:** This pooled analysis shows that in patients with BMI < 30 kg/m<sup>2</sup> glargine is more efficacious and there is less severe hypoglycaemia than with NPH. The incidence of severe nocturnal hypoglycaemia was lower for glargine than NPH irrespective of BMI.

	Body Mass Index				Overall	
	< 30 kg/m <sup>2</sup>		≥ 30 kg/m <sup>2</sup>			
	Glargine	NPH	Glargine	NPH	Glargine	NPH
Δ HbA <sub>1c</sub> , Mean (SD), %	-1.3 (1.2) <sup>a</sup>	-1.1 (1.2)	-1.4 (1.2) <sup>d</sup>	-1.5 (1.1)	-1.3 (1.2) <sup>a</sup>	-1.3 (1.2)
Severe hypoglycaemia, %	2.2 <sup>b</sup>	3.9	1.4 <sup>d</sup>	1.9	2.0 <sup>b</sup>	3.2
Severe nocturnal hypoglycaemia, %	1.0 <sup>c</sup>	2.4	0.2 <sup>e</sup>	1.7	0.7 <sup>f</sup>	2.1

<sup>a</sup>*P* = 0.008; <sup>b</sup>*P* = 0.04; <sup>c</sup>*P* = 0.03; <sup>d</sup>*P* = NS; <sup>e</sup>*P* = 0.02; <sup>f</sup>*P* = 0.002 vs NPH

### Weight change upon initiation of insulin detemir treatment with or without dietary intervention

P.A. Hollander<sup>1</sup>, M. Piletić<sup>2</sup>, H.J. Silver<sup>3</sup>, H. Andersen<sup>4</sup>, L. Conradsen Hiort<sup>4</sup>, K. Niswender<sup>3</sup>

<sup>1</sup>Baylor Endocrine Center, Baylor University Medical Center, Dallas, USA,

<sup>2</sup>General Hospital Novo Mesto, Novo Mesto, Slovenia, <sup>3</sup>Vanderbilt University School of Medicine, Nashville, USA, <sup>4</sup>Novo Nordisk, Søborg, Denmark.

**Background and aims:** Weight gain upon initiation of insulin therapy is counter to clinical goals in diabetes management. The aim of this trial was to determine the impact of a dietary intervention on weight change from baseline when initiating insulin detemir (IDet) in insulin-naïve type 2 diabetes subjects.

**Materials and methods:** In all, 611 insulin-naïve type 2 diabetes subjects were included in a randomised, stratified, controlled, parallel, open-labelled multinational treat-to-target trial. The treatment period was 26 weeks. Subjects received IDet once daily with metformin and were randomised (1:1) to either dietary intervention (IDet+Diet) or no dietary intervention (IDet). Subjects were stratified according to one of 4 BMI strata: 25.0–29.9, 30.0–34.9, 35.0–39.9 and 40.0–45.0 kg/m<sup>2</sup>. Baseline (mean/SD) body weight and HbA<sub>1c</sub> were comparable for subjects randomised to the IDet+Diet group (weight 96.4/18.2 kg; HbA<sub>1c</sub> 8.0/0.7 %) and the IDet group (weight 97/20.4 kg; HbA<sub>1c</sub> 7.9/0.6 %). Subjects in the IDet+Diet group received 3 face-to-face meetings and 3 phone consultations by a certified dietician. Subjects in the IDet group received only basic dietary advice at baseline. Differences between the groups in changes from baseline in body weight, HbA<sub>1c</sub>, fasting plasma glucose (FPG) and hypoglycaemic episodes were analysed after 26 weeks.

**Results:** No differences in demographic or subject characteristics were seen between the groups at baseline. After 26 weeks the estimated mean weight loss (SEM) was 1.05 kg (0.23) (IDet+Diet) and 0.56 kg (0.23) (IDet); the difference was non-significant (*p* = 0.132). In both groups subjects in the highest BMI strata obtained a greater weight reduction compared to subjects in the lowest BMI strata (Figure 1). Both groups obtained a similar improvement in glycaemic control; estimated mean change (SE) in HbA<sub>1c</sub> after 26 weeks was -0.93 % (0.05) (IDet+Diet) and -0.80 % (0.05) (IDet); the difference was NS (*p* = 0.053). Estimated mean change (SE) in FPG was -3.00 mmol/l (0.12) (IDet+Diet) and -2.93 mmol/l (0.12) (IDet). No observed difference in caloric intake was seen; the reduction was 553 kJ (IDet+Diet) and 787 kJ (IDet). The rate (episodes/exposure year) of hypoglycaemic episodes was similar for the two groups: 25.47 episodes (IDet+Diet) and 23.30 episodes (IDet). No significant difference (*p* = 0.691) was seen between the groups; the estimated rate ratio (IDet/IDet+Diet) was 0.96 [0.79; 1.17].

**Conclusion:** An average weight reduction was observed regardless of dietary intervention when initiating insulin detemir in insulin-naïve type 2 diabetes subjects; the difference in weight change between the two groups was non-significant. The weight loss was most pronounced for subjects in the highest BMI strata. Glycaemic control as measured by HbA<sub>1c</sub> and FPG improved similarly in both groups.

### Gradual intensification of premixed insulin lispro therapy vs basal ± mealtime insulin in patients with type 2 diabetes eating light breakfasts

D. Giugliano<sup>1</sup>, V. Woo<sup>2</sup>, S. Shah<sup>3</sup>, M. Tracz<sup>4</sup>, C. Mistodis<sup>5</sup>, A. Calle-Pascual<sup>6</sup>, R. Duarte<sup>7</sup>, R. Sari<sup>8</sup>, J. Deinhard<sup>9</sup>, A.O. Jiletcovici<sup>10</sup>, S. Wille<sup>10</sup>, J. Kiljanski<sup>10</sup>; <sup>1</sup>Second Univ. of Naples, Italy, University of Manitoba Health Sciences Center, Winnipeg, Canada, <sup>2</sup>Diabetes Action Centre, Mumbai, India, <sup>3</sup>Dept of Gastroenterology and Metabolic Diseases, Med University Warsaw, Poland, <sup>4</sup>Spitalul Clinic de Urgenta "Sf. Apostol Andrei", Galati, Romania, <sup>5</sup>Servicio Endocrinologia, Hospital Clinico San Carlos, Madrid, Spain, <sup>6</sup>Eli Lilly and Company, Lisboa, Portugal, <sup>7</sup>Faculty of Medicine, Akdeniz University, Antalya, Turkey, <sup>8</sup>Accovion GmbH, Eschborn, Germany, <sup>9</sup>Eli Lilly and Company, Vienna, Austria.

**Background and aims:** Insulin therapy in type 2 diabetes mellitus (T2DM) should be tailored to individual patients' (pts) needs. We tested if, in those eating light breakfasts, premixed insulin analogues may be an option to substitute basal ± mealtime insulin.

**Materials and methods:** This randomized, open-label, 48-week, parallel arm study compared 2 algorithms of initiation and then intensification of insulin therapy. One, 2 or 3 injections of insulin lispro mix 25 and/or insulin lispro mix 50 (lispro mix algorithm; LM) OR glargine ±1, 2 or 3 injections of insulin lispro (basal ± meal-time insulin algorithm; BM) were used in T2DM pts not controlled with oral antihyperglycaemic medications, consuming <15% daily calories at breakfast. The objective was to test the hypothesis that LM was non-inferior to BM for glycaemic control, measured by HbA1c after 48 weeks, assessed using ANOVA adjusted for baseline HbA1c and with a non-inferiority margin of 0.4%. Post-hoc analyses assessed the mean number of injections/day and percentage of pts achieving <7.0% HbA1c without hypoglycaemia.

**Results:** Pts (n=344: 176 [51%] females, mean [SD] age 54.3 [8.8] years, BMI 29.4 [4.6] kg/m<sup>2</sup>, baseline HbA1c 9.02 [0.97] %) were randomized to LM (n=171) or BM (n=173). In the per-protocol analysis (n=230) "LS means" (95%CI) endpoint HbA1c were 7.40 (7.15 - 7.65) and 7.55 (7.27 - 7.82) in LM and BM arms, respectively. The between-treatment difference was -0.14% (-0.42, 0.13); non-inferiority was met and confirmed in the full analysis set (n=321). Mean HbA1c changes at Week 48 were -1.68% (1.35) (LM) and -1.66% (1.31) (BM); p=0.967. Mean number of insulin injections/day at Week 48 was 1.96 in the LM and 1.99 in the glargine arm. HbA1c targets of <7.0% were achieved by 48.2% (LM) vs. 36.2% (BM) and ≤6.5% were achieved by 24.8% (LM) vs. 18.5% (BM) of pts. The percentage of pts achieving HbA1c <7.0% without hypoglycaemia was 13.1% and 8.5%, respectively at Week 48; p=0.251. SMBG profiles, body weight changes of +2.31 (3.3) kg and +2.32 (3.7) kg, and total insulin doses of 46.20 (28.4) IU/day and 46.45 (31.4) IU/day at Week 48 were similar in LM and BM, respectively. Overall (65% vs. 60%) and severe hypoglycaemia rate (2% vs. 4%) were similar in LM and BM groups (p=0.75); however, more LM pts had nocturnal symptomatic episodes (27.8% vs. 17.9%; p=0.039).

**Conclusion:** This study met the primary objective of establishing non-inferiority of an insulin mixtures-based regimen to a basal ± meal-time insulin regimen in achieving glycaemic control of T2DM patients eating a light breakfast, which is peculiar in countries with a Mediterranean diet.

### The way of insulin introduction more than the target glucose level determines the outcomes of critically ill patients with type 2 diabetes mellitus

N.G. Belyaeva, E.S. Komissarova, L.G. Strongin, S.A. Tezyaeva; State Medical Academy, Nizhny Novgorod, Russian Federation.

**Background and aims:** NICE-SUGAR has shown worsening of outcomes in maintenance of blood glucose level less than 6,1 mmol/l in critically ill patients with type 2 diabetes mellitus. The purpose of the present research is to compare the outcomes in different target glucose levels: 6,5-8,5 mmol/l and 8,6-11,0 mmol/l considering the way of insulin therapy.

**Materials and methods:** At the time of admission to the intensive care unit, 88 patients with various surgical pathology and type 2 diabetes mellitus, or hyperglycemia >11 mmol/l were randomly assigned to 4 groups. In group 1 (n=25) and 2 (n=20) the target glucose level 6,5-8,5 mmol/l was supported. In group 3 (n=21) and 4 (n=22) the level of glycemia 8,6-11,0 mmol/l was maintained. There were no differences in the baselin characteristics between the groups. The control of blood glucose level during the first 72 hours was carried out by intravenous infusion of short - acting insulin (in group 1 and 3), and by subcutaneous injections (in group 2 and 4). Risk scoring was performed using Acute Physiology and Chronic Health Evaluation (APACHE) score. Quantity of hypoglycemias and 90 - day survival rate were estimated.

**Results:** There were no significant differences between groups 1,2,3,4 in symptomatic hypoglycemias (p=0,5). Hypoglycemias less than 3,9 mmol/l were more often in the groups of subcutaneous injections (p=0,045). Parameters of gravity according to the APACHE score have decreased in group 1 on 10,0 (5,9-11,5) points, in group 3 - on 8,1 (5,9-9,6) points, in group 4 - on 6,9 (6,0-9,3), in group 2 - on 6,3 (5,2-11,3) points. 90-day survival rate shows the dependence only from the way of introduction of insulin 96%,50%,97,6%, 54,5% in groups 1,2,3,4 accordingly (p=0,03).

**Conclusion:** 90- day survival rate and dynamics of gravity according to APACHE score in critically ill patients with type 2 diabetes mellitus was significantly better, hypoglycemic effects were observed less often in the groups of insulin injections in both target glucose levels. However there were no significant differences in these parameters between groups with different target glucose levels when we used the same method of insulin treatment,

## 942

### Reduced physical activity one year after initiation of insulin therapy in patients with type 2 diabetes mellitus: results of a prospective study

H. Jansen, G. Vervoort, C. Tack; Radboud University Nijmegen Medical Centre, Netherlands.

**Background and aims:** Insulin therapy is frequently needed to achieve adequate glycaemic control in patients with type 2 diabetes mellitus (T2DM), but often at the expense of significant weight gain. Weight gain is partly explained by correction of glucose control, but other factors are largely unknown. We hypothesized that a decrease in physical activity may contribute to insulin-associated weight gain. This hypothesis was prospectively tested in a group of patients starting on insulin therapy.

**Materials and methods:** A total of 58 insulin-naïve patients with type 2 diabetes mellitus (M:F 32:26, mean age 61 ± 10 yr; mean diabetes duration 9 yr) were included. Physical activity was measured quantitatively using a SenseWear Pro Armband™ at baseline and after 12 months of insulin therapy. In addition, body weight, insulin dose and glycaemic control (HbA1c) were determined before and after 12 months of insulin therapy.

**Results:** After 12 months insulin therapy, mean body weight had increased by 3.6 ± 5.0 kg (SD) (range -5.8 to +21.0 kg; 55 % of the patients showed pronounced weight gain of ≥ 3 kg); HbA1c decreased from 8.9 ± 1.7 to 7.5 ± 1.1 % (both P < 0.05). Mean insulin dose at 12 months was 48 ± 33 U/day (0.51 U/kg insulin). Mean physical activity expressed as metabolic equivalent (METs) was significant lower at 12 months of insulin therapy compared to baseline (1.44 ± 0.29 vs. 1.36 ± 0.28; P < 0.05). Also the average number of steps per

day significantly diminished after 12 months of insulin treatment compared to baseline (baseline:  $6757 \pm 3432$  vs.  $5952 \pm 2755$  at 12 months of insulin,  $P < 0.05$ ). There was no correlation between the change in body weight over 12 months and the change in physical activity level.

**Conclusion:** Physical activity is decreased after 12 months of insulin therapy in patients with type 2 diabetes mellitus. Whether the decrease in physical activity is partly a cause of insulin-induced weight gain or merely a consequence remains to be determined.

**A pooled analysis of patients with type 2 diabetes mellitus to evaluate the efficacy and safety of a basal-bolus regimen across different age groups**

A. Cali<sup>1</sup>, G. Dailey<sup>2</sup>, J. Lin<sup>3</sup>, E. Wang<sup>4</sup>;

<sup>1</sup>Sanofi, Paris, France, <sup>2</sup>Scripps Clinic and Research Foundation, La Jolla, USA, <sup>3</sup>Novosys Health, Flemington, USA, <sup>4</sup>Sanofi, Bridgewater, USA.

**Background and aims:** Basal-bolus (mealtime bolus doses of insulin added to basal insulin) refers to a type of diabetes treatment intensification regimen that is prescribed for both young and older patients with type 2 diabetes mellitus. We evaluated the efficacy and safety of adding mealtime insulin glulisine to basal insulin across 3 different age groups ( $< 55$ ,  $55$ – $64$ , and  $\geq 65$  years).

**Materials and methods:** Data were pooled from 5 randomised, multicentre studies examining patients with poor glycaemic control who were initiated on basal insulin to which insulin glulisine was added at mealtime, with age group ranges approximating tertiles. Patients were treated for up to 6 months. Demographic information and efficacy and safety data were collected at baseline and at each study's endpoint.

**Results:** A total of 1413 patients were analysed (49.5% female). A total of 32.2% ( $n = 455$ ) were  $< 55$  years of age, 42.6% ( $n = 602$ ) were  $55$  to  $64$  years of age, and 25.2% ( $n = 356$ ) were  $\geq 65$  years of age. Mean body mass index for those  $< 55$ ,  $55$  to  $64$ , and  $\geq 65$  years of age was  $35.6 \text{ kg/m}^2$ ,  $34.2 \text{ kg/m}^2$ , and  $32.0 \text{ kg/m}^2$ , respectively. The basal-bolus regimen resulted in significant decreases in  $\text{HbA}_{1c}$  between baseline and study end in all 3 age groups (all  $P < 0.001$ ; Table). Among the 3 age groups, this change was similar (Table). Target  $\text{HbA}_{1c}$  ( $< 7\%$ ) was reached by 45.5%, 50.3%, and 54.5% in the  $< 55$ ,  $55$  to  $64$ , and  $\geq 65$  year cohorts, respectively. Incidence of severe hypoglycaemia (as defined in each trial protocol) was similar (Table). There was weight gain in each age group ( $P < 0.001$ ), with significantly less weight gain in the two older groups.

**Conclusion:** This pooled analysis suggests that basal-bolus treatment with mealtime insulin glulisine added to basal insulin significantly and clinically reduces  $\text{HbA}_{1c}$  across different age groups, including the older groups, with similar rates of severe hypoglycaemia. In addition, there was less weight gain in the older patients compared to younger patients.

Age range, year	<55	55 to 64	$\geq 65$	P value (between age groups)
Patients, n	455	602	356	
$\text{HbA}_{1c}$ at baseline, %	8.1 (1.0)	7.8 (0.9)	7.7 (0.9)	$< 0.01$
$\text{HbA}_{1c}$ at endpoint, %	7.3 (1.1)	7.0 (0.9)	6.9 (0.8)	$< 0.01$
$\Delta \text{HbA}_{1c}$ between baseline and endpoint, %	-0.8* (1.1)	-0.8* (1.0)	-0.8* (1.0)	0.8
$\Delta$ Weight, kg	3.5 (4.8)	2.3 (4.4)	2.1 (3.8)	$< 0.01$

**Relative contribution of basal and postprandial blood glucose to hyperglycaemia in patients (Pts) with type 2 diabetes mellitus enrolled in the START study**

S. Harris<sup>1</sup>, J.-F. Yale<sup>2</sup>, B. Abbaszadeh<sup>3</sup>, J. Stewart<sup>3</sup>, L. Berard<sup>4</sup>;

<sup>1</sup>Western University, London, <sup>2</sup>McGill University, Montreal, <sup>3</sup>Sanofi, Laval, <sup>4</sup>Health Science Centre, Winnipeg, Canada.

**Background and aims:** Recent studies have described the relative contribution of Basal Blood Glucose (BBG) and Postprandial Blood Glucose (PPBG) across various  $\text{HbA}_{1c}$  (A1c) values, but very few studies demonstrated the PPBG contribution in both insulin naïve (IN) and insulin treated (IT) Pts with T2DM. The START study compared a patient-driven algorithm for titrating insulin glargine (iGla) and insulin glulisine (iGlu) to a physician-driven algorithm for insulin intensification in Pts with T2DM not at target. The run-in phase (RI-P) of START study provided an opportunity to describe the relative

contributions of PPBG and BBG in IN and IT Pts utilizing 7-point glucose profiles prior to and following the initiation and/or optimization of iGla for 12 weeks.

**Materials and methods:** In this open-label, multicenter, randomized, comparative, Canadian study, uncontrolled Pts with T2DM receiving basal insulin  $\pm$  oral antihyperglycemic drugs (OADs) or IN on 2–3 OADs were eligible to participate. Pts entered RI-P, during which they received iGla using simple titration algorithm. At the end of RI-P, all Pts were on a stable dose of basal insulin. Patients with an A1c still above 7.0% were randomized into a patient or physician-driven algorithm using iGlu titration for 24 weeks to achieve optimal glycemic control. Pts with complete 7-point glucose profiles at baseline and at the end of the RI-P were included in this analysis. The area under the curve (AUC) was partitioned into three parts: area above the fasting plasma glucose (AUCp), area between the fasting plasma glucose and 5.5 mmol/L (AUCb), and the area below 5.5 mmol/L. The percent for the PPBG and BBG contribution were calculated as  $100 \times \text{AUCp}/(\text{AUCb} + \text{AUCp})$  and  $100 \times \text{AUCb}/(\text{AUCb} + \text{AUCp})$  respectively.

**Results:** There were 214 IN and 212 IT Pts whose mean ages (years) were 58.5 and 60.2 and percent males were 64.5 and 56.1, respectively. Mean A1c at baseline was 9.3 and 8.6 for IN and IT Pts respectively. After 12 weeks of initiating or optimizing iGla mean A1c and FPG change were -0.83% and -3.2 mmol/L. A1c reduction was higher in IN than IT (-1.21 vs -0.45). The result for PPBG and BBG contribution to hyperglycemia are shown in the table.

**Conclusion:** The RI-P results of the START study showed that the glucose profile of IN and IT Pts are different depending on their relative A1c levels. In IN Pts with A1c below 8.5%, the contribution of PPBG to hyperglycemia is higher than for A1c above 8.5%. In IT Pts, PPBG contribution to hyperglycemia is higher or equal to BBG contribution in Pts with A1c below 9%. Initiating or optimizing iGla as expected corrects for BBG hyperglycemia and increased PPBG contribution across all A1c levels. These findings suggest that depending on the A1c and whether or not a patient is already on basal insulin, an individualized approach should be considered for initiating or intensifying treatment in Pts with T2DM above the A1c of 7%.

	Baseline			Run-in phase Results 12 weeks following initiation or optimization of insulin glargine

### Lower incidence of diabetic complications with insulin glargine versus basal human insulins in patients with type 1 or type 2 diabetes: a population-based cohort study in Italy

S. Cammarota<sup>1</sup>, D. Bruzzese<sup>2</sup>, A.L. Catapano<sup>3</sup>, A. Citarella<sup>1</sup>, L. De Luca<sup>1</sup>, L. Manzoli<sup>4</sup>, M. Masulli<sup>5</sup>, E. Menditto<sup>1</sup>, A. Mezzetti<sup>6</sup>, S. Riegler<sup>1</sup>, D. Putignano<sup>1</sup>, E. Tragni<sup>3</sup>, E. Novellino<sup>1</sup>, G. Riccardi<sup>5</sup>

<sup>1</sup>Center of Pharmacoeconomics and Drug Utilization, "Federico II" University, Naples, <sup>2</sup>Department of Preventive Medical Sciences, "Federico II" University, Naples, <sup>3</sup>Department of Pharmacological Sciences, University of Milan, <sup>4</sup>Section of Hygiene, Epidemiology, Pharmacology and Legal Medicine, G. D'Annunzio University Foundation, Chieti, <sup>5</sup>Department of Clinical and Experimental Medicine, "Federico II" University, Naples, <sup>6</sup>Clinical Research Centre, G. D'Annunzio, Chieti, Italy.

**Background and aims:** Several studies have demonstrated that the introduction of both rapid- and long-acting insulin analogues may help to achieve better glycemic control with less hypoglycemic episodes than the traditional human insulin (HI) formulations. It remains unknown whether insulin analogues are also better in reducing long-term diabetic complications. Aim of this study was to compare the use of insulin glargine and intermediate/long-acting HI in relation to the first occurrence of diabetes-related complications in a cohort of diabetic patients.

**Materials and methods:** A population-based cohort study was conducted using administrative data from four local health authorities in the Abruzzo Region (900,000 inhabitants). A record linkage-analysis was done to identify diabetic patients free of macrovascular disease at baseline and consistently treated with insulin glargine or intermediate/long-acting HI during a 3-year follow-up. Patients were followed from January 1, 2006 until the date of hospital admission for any diabetes-related complications, censoring (death or emigration), or December 31, 2008, whichever occurred first. HRs and 95% CIs of any diabetic complication and macrovascular, microvascular and metabolic complications were estimated separately using Cox proportional hazard models adjusted for age, gender, previous microvascular or metabolic complications, concomitant drugs and anti-diabetic drugs use. Propensity score matching was also used to adjust for differences in cardiovascular risk markers between the two treatment groups.

**Results:** Overall, 1,921 diabetic patients were included: 744 intermediate/long-acting HI users and 1,177 insulin glargine users. During the 3-year follow-up, 209 incident events of any diabetes-related complication in the intermediate/long-acting HI group (28.1%, 123 events per 1,000 person-years at risk) and 159 in the insulin glargine group (13.5%, 50 events per 1,000 person-years at risk) occurred. After adjustment for covariates, insulin glargine users had a HR (95% CI) of 0.58 (0.45–0.74) for any diabetes-related complication and HRs of 0.63 (0.47–0.86), 0.55 (0.32–0.96) and 0.38 (0.19–0.73) for macrovascular, microvascular and metabolic complications, respectively, as compared with intermediate/long-acting HI users. Propensity score-based matched-pair analyses supported these findings.

**Conclusion:** Our results suggest that the use of insulin glargine compared with traditional basal insulins is associated with a lower risk of diabetic complications; long-term controlled intervention trials are needed to confirm this hypothesis.

Supported by: "Federico II" University of Naples

## 946

### Insulin glargine metabolite M1 is the principal insulin component circulating in plasma of young children with type 1 diabetes: Results from the PRESCHOOL study

T. Danne<sup>1</sup>, P. Johnston<sup>2</sup>, G. Xiang<sup>3</sup>, A. Cali<sup>4</sup>, M.-P. Dain<sup>4</sup>, A. Philotheou<sup>5</sup>, <sup>1</sup>Kinder- und Jugendkrankenhaus 'Auf der Bult', Hannover, Germany, <sup>2</sup>Sanofi, Bridgewater, USA, <sup>3</sup>Fewmo Technology Co.LTD, Beijing, China, <sup>4</sup>Sanofi, Paris, France, <sup>5</sup>UCT Private Academic Hospital, Cape Town, South Africa.

**Background and aims:** The principal circulating component in plasma of adults is insulin glargine metabolite M1, but the metabolism of insulin glargine has not been studied in young children. The objective of this study was to examine the metabolism of insulin glargine in young children in order to rule out accumulation of insulin glargine in this population. Ct.gov NCT00993473.

**Materials and methods:** Children with type 1 diabetes from the PRESCHOOL study, aged 1 to 6 years, who were treated with insulin glargine for 24 weeks (n = 61) had blood samples drawn at Weeks 1, 2, and 4 approximately 24 hours after the last dose for pharmacokinetic analysis of plasma levels of glargine and its metabolites. C<sub>trough</sub> values for insulin glargine and its metabolites M1 and M2 were determined using LC-MS/MS. The lower limit of quantification was 0.2 ng/mL for parent and each metabolite.

**Results:** Insulin glargine metabolite M1 was the principal circulating component in plasma. Mean (SD) plasma M1 C<sub>trough</sub> values were 0.580 (0.786), 0.458 (0.700), and 0.452 (0.583) ng/mL at Weeks 1, 2, and 4, respectively, indicating no accumulation of M1. The standard deviation was observed to not change over time. Mean insulin glargine parent and metabolite M2 concentrations were below the level of quantification. Similar results have been observed in adults.

**Conclusion:** For young children with type 1 diabetes, the principal circulating insulin component in plasma was insulin glargine metabolite M1, known to be the pharmacologically active component. Since M1 does not differ from human insulin in terms of binding to IGF-1R and in mitogenesis, these data provide additional evidence for the safety profile of insulin glargine in young children.

Clinical Trial Registration Number: NCT00993473

**Improved glycaemic control with once-daily insulin glargine in people with type 2 diabetes inadequately controlled on insulin detemir/OAD combination therapy (RESOLUTE)**L. Lieve<sup>1</sup>, M. Rodriguez<sup>2</sup>, L. Czupryniak<sup>3</sup>, W. Landgraf<sup>4</sup>, V. Pilorget<sup>5</sup>, M.-P. Dain<sup>5</sup>, M. Kvapil<sup>6</sup><sup>1</sup>Maxima Medical Centre, Eindhoven, Netherlands, <sup>2</sup>University Hospital, Mendoza, Argentina, <sup>3</sup>University of Lodz, Poland, <sup>4</sup>Sanofi, Frankfurt, Germany, <sup>5</sup>Sanofi, Paris, France, <sup>6</sup>University Hospital Motol, Prague, Czech Republic.

**Background and aims:** Evidence from a randomised clinical trial indicates clinically relevant differences in efficacy between basal insulin glargine (GLA) and insulin detemir (DET) when used once-daily. We investigated whether patients with type 2 diabetes (T2D) inadequately controlled with DET therapy in combination with oral anti-diabetic agents (OADs) would benefit from switching to GLA treatment in everyday clinical practice.

**Materials and methods:** RESOLUTE was a multi-national (5 countries), non-interventional, 6-month, prospective, observational study performed between June 2010 and November 2011 in 88 office- and hospital-based diabetes centres. Patients with T2D treated for  $\geq 3$  months with DET (QD or BID) combined with OADs and having an HbA<sub>1c</sub>  $> 7\%$  to  $10\%$  were eligible when switched to GLA at the physician's discretion. The primary endpoint was the change in HbA<sub>1c</sub> after 6 months. The main secondary endpoints included fasting plasma glucose (FPG), insulin dose, body weight, hypoglycaemia over the last month and adverse events.

**Results:** Of 564 patients included in the study, 511 were eligible for analysis, of whom 59% previously received QD DET and 40% BID DET in addition to OADs (92% received metformin and/or SU). Patient characteristics (61% female) were (mean [SD]): age, 61.9 (10.1) years; BMI, 30.9 (5.1) kg/m<sup>2</sup>; duration of diabetes, 9.2 (5.9) years. Patients were on DET therapy for 14.4 (12.7) months with 28.4 (17.1) U/day. GLA was initiated once-daily at bedtime (79%), dinner (11%) or breakfast (8%) in 98% of patients. After a mean follow-up period of 186 (17) days, mean HbA<sub>1c</sub> decreased from 8.37% (0.77) to 7.32% (0.95) ( $P < 0.0001$ ) and mean FPG from 8.9 (2.1) mmol/L to 6.8 (1.7) mmol/L ( $P < 0.0001$ ). Glycaemic improvements were more pronounced in former BID DET patients (table). At study end, 40% of patients reached HbA<sub>1c</sub>  $< 7\%$  and 25% were between 7% and 7.5%. OAD co-medication was continued in a comparable manner during follow-up. Mean body weight slightly decreased (-0.2 [2.5] kg), and the percentage of patients with reported symptomatic (9.4%), nocturnal (3.1%) and severe (0%) hypoglycaemia in the last month of GLA therapy was consistently lower compared with the last month of previous DET treatment (16.4%, 8.2% and 1.2%, respectively). The number of patients who reported adverse events was low with GLA (2.4%).

**Conclusion:** Under real-life conditions in poorly controlled patients with T2D, replacement of QD or BID DET with once-daily GLA resulted in a clinically relevant improvement in glycaemic control without increased hypoglycaemia risk or weight gain.

**Study of Once-Daily Levemir (SOLVE™): Patient quality of life and physician resource utilisation of once-daily insulin detemir in Chinese patients with type 2 diabetes**C. Pan<sup>1</sup>, J. Lu<sup>1</sup>, P. Wang<sup>2</sup>, Q. Ji<sup>3</sup>, L. Ji<sup>4</sup><sup>1</sup>Chinese PLA General Hospital, Beijing, <sup>2</sup>Tianjin Medical University Metabolic Diseases Hospital, Tianjin, <sup>3</sup>Xijing Hospital affiliated to 4th Military Medical University, Xi'an, <sup>4</sup>Peking University People's Hospital, Beijing, China.

**Background and aims:** Barriers to insulin initiation in people with type 2 diabetes mellitus (T2DM) include fear of increased treatment complexity by both patients and healthcare professionals, and a perceived lack of time and resources by primary care physicians. SOLVE™ was a 24-week international observational study of insulin detemir initiation in patients with T2DM previously treated with one or more oral antidiabetic drugs (OADs) across 10 countries. This abstract reports the effect of insulin detemir initiation on patient quality of life and resource utilization based on a sub-analysis of data from China.

**Materials and methods:** Patient quality of life was assessed at baseline and end of study using the Insulin Treatment Appraisal Scale (ITAS) - a self-assessment questionnaire comprising 20 items (16 negative items and 4 positive items) with 5 categories of 'strongly disagree', 'disagree', 'neither agree nor disagree', 'agree' and 'strongly agree'. Physician resource utilization was self-assessed by a questionnaire.

**Results:** A total of 3272 patients were enrolled in China. Of these, 2988 patients (91.3%) completed the 24-week study (58% male, age 56.2 $\pm$ 10.8 years, BMI 25.3 $\pm$ 3.3 kg/m<sup>2</sup>, duration of diabetes 7.1 $\pm$ 5.2 years, OAD therapy 6.3 $\pm$ 5.1 years). During the study period, neither serious adverse drug reactions nor major hypoglycemic events were reported. Insulin dose at the end

of the study was  $0.24 \pm 0.11$  U/kg.  $HbA_{1c}$  improved by  $-1.2 \pm 1.7\%$  ( $p < 0.001$ ). The ITAS questionnaire was completed by 2872 patients. The main concerns of initiating insulin at baseline were (reported as percentages of patients agree or strongly agree): item 18: 'Being on insulin causes family and friends to be more concerned about me' (64.7%), item 1: 'Taking insulin means I have failed to manage my diabetes with diet and tablets' (53.3%) and item 20: 'Taking insulin makes me more dependent on my doctor' (52.3%). After the 24-week treatment, the largest changes in attitudes occurred in relation to the following items: Item 19: 'Taking insulin means help to improve my energy level' (from 59.0% at baseline to 77.5% at Week 24); Item 6: 'I am afraid of injecting myself with a needle' (from 34.5% to 17.4%); and Item 1: 'Taking insulin means I have failed to manage my diabetes with diet and tablets' (from 53.3% to 44.8%); all of which improved after initiating insulin. A total of 3272 physician resource utilisation questionnaires were collected. It was reported that NovoPen 4 was the preferred device (45.0%). The time taken to teach patients to self-inject and perform dose self-adjustment was  $13.4 \pm 9.79$  minutes and  $11.4 \pm 9.32$  minutes, respectively. Only 2.2% of physicians reported the use of insulin detemir by patients as difficult or very difficult; and only 8.8% of physicians reported being dissatisfied or very dissatisfied with  $HbA_{1c}$  target achieved by the end of the study.

**Conclusion:** Initiating insulin detemir therapy once daily as add-on to OADs was safe and effective for Chinese patients with T2DM, and it was not perceived as being difficult by patients as reported by physicians. Patients' perceptions and satisfaction of insulin treatment improved after initiation of insulin.

### Superior glycaemic control with once-daily IDegAsp vs insulin glargine in Japanese adults with type 2 diabetes mellitus inadequately controlled with OADs: a randomised controlled, phase 3 trial

S. Nakamura<sup>1</sup>, Y. Ono<sup>2</sup>, R. Rabol<sup>3</sup>, L. Endahl<sup>3</sup>, Y. Onishi<sup>4</sup>

<sup>1</sup>Internal Medicine, Iryo Houjin Shadan Kowakai Heiwadai Hospital, Miyazaki, Japan, <sup>2</sup>Takagi Hospital, Fukuoka, Japan, <sup>3</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>4</sup>Division of Diabetes and Metabolism, Institute for Adult Diseases, Asahi Life Foundation in Tokyo, Japan.

**Background and aims:** Insulin degludec (IDeg) is a new basal insulin that forms soluble multi-hexamers upon s.c. injection, resulting in an ultra-long and consistent glucose-lowering effect. Insulin degludec/insulin aspart (IDegAsp) is a soluble co-formulation of IDeg (70%) and insulin aspart (30%) that provides both mealtime and basal insulin coverage. We investigated the efficacy and safety of IDegAsp in insulin-naïve Japanese adults with type 2 diabetes inadequately controlled on oral antidiabetic drugs (OADs) in a phase 3, 26-week, open-label, treat-to-target trial.

**Materials and methods:** Participants (mean: 60.5 years old;  $HbA_{1c}$  8.4%; fasting plasma glucose [FPG] 9.0 mmol/L; BMI 25.1 kg/m<sup>2</sup>; duration of diabetes 11.7 years) were randomised to once-daily injections of IDegAsp ( $n=147$ ) or insulin glargine (IGlar;  $n=149$ ), both with/without up to 2 OADs (excluding sulphonylureas, dipeptidyl peptidase-4 inhibitors and glinides). IDegAsp was injected before the largest meal of the day at the discretion of each participant (and maintained throughout the trial); IGlar was injected at the same time each day according to label. Both insulins were titrated to an FPG  $< 5$  mmol/L. **Results:** After 26 weeks, mean  $HbA_{1c}$  was 7.0% with IDegAsp and 7.3% with IGlar. Analysis of change in  $HbA_{1c}$  from baseline to end-of-trial demonstrated that IDegAsp was superior to IGlar (estimated treatment difference (ETD) IDegAsp-IGlar:  $-0.28\%$  [-0.46; -0.10]<sub>95% CI</sub>,  $p < 0.001$ ). At end-of-trial, a greater proportion of subjects achieved  $HbA_{1c} < 7.0\%$  with IDegAsp (58.5%) vs. IGlar (40.3%). Mean FPG was similar for IDegAsp and IGlar (5.7 vs. 5.6 mmol/L; ETD IDegAsp-IGlar: 0.15 mmol/L [-0.29; 0.60],  $p=NS$ ). No severe hypoglycaemia was reported. Confirmed hypoglycaemia (PG  $< 3.1$  mmol/L) was reported for 44% of subjects in both groups; IDegAsp was associated with a numerically lower (27%) rate of confirmed hypoglycaemia than IGlar (estimated rate ratio (ERR) IDegAsp/IGlar: 0.73 [0.50; 1.08]  $p=NS$ ). A significantly greater proportion of subjects achieved  $HbA_{1c} < 7.0\%$  at end-of-trial (without confirmed hypoglycaemia in the last 12 weeks of treatment) with IDegAsp compared to IGlar (43% vs. 25%; Odds Ratio 2.21 [1.25; 3.92],  $p=0.003$ ). The rate of nocturnal confirmed hypoglycaemia (confirmed hypoglycaemia with onset between 00:01-05:59 h) was numerically lower (by 25%) with IDegAsp than IGlar (RR: 0.75 [0.34; 1.64],  $p=NS$ ). Mean daily insulin doses were similar between groups at the end-of-trial (IDegAsp: 28 U; IGlar: 29 U) as were increases in body weight from baseline (0.7 kg for both

groups). Overall rates of adverse events were similar between groups with no treatment-specific pattern or clustering.

**Conclusion:** IDegAsp dosed once daily with the largest meal of the day provided superior long-term glycaemic control with similar FPG to IGlar at a numerically lower rate of overall and nocturnal hypoglycaemia.

## 950

### Comparing the efficacy of biphasic insulin aspart-30 and insulin detemir given in the morning as an add-on to type 2 diabetic patients treated with OHA by using CGM

D. Tsujino, R. Nishimura, C. Seo, K. Andou, A. Morimoto, K. Utsunomiya; Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.

**Aims:** To compare the efficacy of biphasic insulin aspart-30 (A) and insulin detemir (D) given in the morning as an add-on to type 2 diabetic patients treated with oral hypoglycaemic agents (OHA).

**Methods:** This study enrolled 25 poorly controlled type 2 diabetic patients ( $8\% < HbA_{1c} < 11\%$ ) being treated with OHA mono- or combination therapy consisting of sulphonylureas, thiazolidinediones or biguanides. The patients were randomly assigned to A or D, which were administered in the morning as an add-on to OHA mono- or combination therapy, with the baseline-dosing methods maintained after allocation. After adjusting their insulin dosages over a period of  $\geq 2$  months to achieve predinner glucose levels  $< 130$  mg/dL, the patients were hospitalised and monitored by CGM for 3 days. Day 2 CGM data were subjected to analysis for comparison. The t-test was used to compare the 24-hour mean glucose levels and their standard deviations (SDs) in groups A and D; the mean amplitude of glucose excursions (MAGE), the proportion of time in hypoglycaemia (180 mg/dL), the postprandial peak glucose levels, the range of postprandial glucose increases and the time from preprandial glucose levels to postprandial peak glucose levels. The present study was conducted with the approval of the Institutional Review Board at our university.

**Results:** There was no significant difference in the patients' backgrounds between groups A and D [males/females, 7/5 vs. 9/4; age (mean  $\pm$  SD),  $59.9 \pm 10.2$  vs.  $61.3 \pm 6.9$  years; and BMI,  $26.9 \pm 4.2$  vs.  $24.8 \pm 3.5$  kg/m<sup>2</sup>], as well as in baseline  $HbA_{1c}$  levels ( $9.16 \pm 0.49$  vs.  $9.02 \pm 0.42\%$ ), insulin dosages at admission ( $0.117 \pm 0.067$  vs.  $0.115 \pm 0.071$  U/kg per day) or decreases in  $HbA_{1c}$  from the start of insulin to admission ( $-1.17 \pm 0.43$  vs.  $-1.14 \pm 0.75\%$ ). The 24-hour mean glucose levels and their SDs were not significantly different between groups A and D ( $162 \pm 29$  vs.  $155 \pm 16$  mg/dL and  $33.8 \pm 16.1$  vs.  $42.1 \pm 9.1$  vs., respectively). The MAGE was significantly lower in group A ( $75 \pm 35$ ) than in group D ( $103 \pm 13$ ) ( $P = 0.020$ ), and the time in hypoglycaemia tended to be shorter in group A ( $0.4 \pm 1.4$  min) than in group D ( $16.5 \pm 27.3$ ) ( $P = 0.055$ ), whereas the time in hyperglycaemia was not significantly different. Postprandial glucose increases were significantly narrower in range after breakfast in group A ( $63 \pm 34$ ) than in group D ( $105 \pm 34$ ) ( $P = 0.005$ ), with the postprandial peak glucose levels after breakfast tending to be lower in group A ( $210 \pm 49$  mg/dL) than in group D ( $243 \pm 33$  mg/dL) ( $P = 0.055$ ). The time to postprandial peak glucose levels tended to be shorter in group A than in group D (breakfast,  $86 \pm 25$  min vs.  $110 \pm 36$ ,  $P = 0.066$ ; dinner,  $74 \pm 34$  min vs.  $101 \pm 24$ ,  $P = 0.033$ ).

**Conclusion:** A comparison of glycaemic variations in type 2 diabetic patients by CGM demonstrated significantly lower MAGE with A than with D; the difference was mainly due to significantly greater reductions in glucose increases after breakfast.

**Predictors of good blood glucose control in people receiving biphasic insulin aspart 30 premix insulin: data from the A<sub>1</sub>chieve study**P.D. Home<sup>1</sup>, Z.A. Latif<sup>2</sup>, P. Soewondo<sup>3</sup>, G. Gonzalez-Galvez<sup>4</sup>, V. Prusty<sup>5</sup>, Y. Li<sup>6</sup>;<sup>1</sup>Institute of Cellular Medicine – Diabetes, Newcastle University, UK,<sup>2</sup>BIRDEM, Dhaka, Bangladesh, <sup>3</sup>Faculty of Medicine, Jakarta, Indonesia,<sup>4</sup>Instituto Jalisciense de Investigacion en Diabetes y Obesidad, SC, Jalisco, Mexico, <sup>5</sup>Novo Nordisk Pharmaceuticals, Zurich, Switzerland, <sup>6</sup>Peking Union Medical College Hospital, Beijing, China.

**Background and aims:** Premix insulins, including biphasic insulin aspart 30, are widely used to enable the effective management of both basal and prandial glucose. Target HbA<sub>1c</sub> levels have been shown to be achievable in up to 66% of people with type 2 diabetes. The present subgroup analysis of the A<sub>1</sub>chieve study investigated which factors predicted the achievement of an HbA<sub>1c</sub> level of <7.0 % in a large population starting aspart premix 30.

**Materials and methods:** A<sub>1</sub>chieve was an international, prospective, multi-centre, non-interventional, 24-week study evaluating the safety and clinical effectiveness of insulin analogues in 66 726 people with type 2 diabetes. In this subanalysis, data from people receiving aspart premix 30 were examined to elucidate baseline characteristics which were statistically correlated with attainment of good blood glucose control, defined as HbA<sub>1c</sub> <7.0 %, at week 24. All statistical analyses were two sided, using a pre-specified 5% significance level, unless otherwise stated.

**Results:** Data from 29 834 participants begun on aspart premix 30 were analysed. Of these 9387 people achieved HbA<sub>1c</sub> <7.0 % by week 24. In this group HbA<sub>1c</sub> fell from 9.0 (SD 1.8) to 6.4 (0.4) % (mean change -2.6 [1.8] %), and fasting plasma glucose (FPG) from 10.4 (3.2) to 6.3 (1.1) mmol/l (change -4.1 [3.2] mmol/l). Multivariate analysis indicated that, after adjustment for differences between regions, the factors identified as predictors of an HbA<sub>1c</sub> of <7.0 % were shorter duration of diabetes, lower baseline BMI, HbA<sub>1c</sub> and triglycerides, and a lower prevalence of microvascular complications (Table). Age, FPG, postprandial glucose and systolic blood pressure at baseline did not emerge as independent predictors.

**Conclusion:** Several factors did predict achievement of target HbA<sub>1c</sub> levels in people with type 2 diabetes starting aspart premix 30. These seem to be markers of lesser overall metabolic disturbance and shorter duration of diabetes.

	Odds ratio (95% CI)	p
Duration of diabetes (per yr)	0.98 (0.97;0.99)	<0.001
BMI (per kg/m <sup>2</sup> )	0.98 (0.97;0.99)	0.01
HbA <sub>1c</sub> (per % unit)	0.77 (0.75;0.80)	<0.001
Quality of life (per 10% EQ-5D)	1.04 (1.002;1.09)	0.04
Total serum cholesterol (per mmol/l)	1.07 (1.02;1.12)	0.01
Serum triglycerides (per mmol/l)	0.90 (0.85;0.95)	<0.001
Microvascular complications (yes/no)	0.93 (0.88;0.99)	0.02
Baseline predictors of HbA <sub>1c</sub> <7.0 % 24 weeks after starting aspart premix 30

**Association of glycaemic control and hypoglycaemia with personality traits and resilience of patients with diabetes**W.C. Kewelow<sup>1</sup>, F. Zillich<sup>2</sup>, K. Wick<sup>2</sup>, N. Müller<sup>1</sup>, C. Kloos<sup>1</sup>, T. Lehmann<sup>3</sup>, G. Wolf<sup>1</sup>, U.A. Müller<sup>1</sup>;<sup>1</sup>Endocrinology and Metabolic Diseases, Internal Medicine III, University Hospital, <sup>2</sup>Institute of Psychosocial Medicine and Psychotherapy, University Hospital, <sup>3</sup>Institute of Medical Statistics, Information Sciences and Documentation, University Hospital, Jena, Germany.

**Background and aims:** Structured therapy and education programs for patients with type 1 (T1DM) and type 2 diabetes (T2DM) have been shown to improve HbA<sub>1c</sub> and to reduce rates of hypoglycaemia as well as the individual dose adjustment. But not all patients succeed to reach their treatment goals after participating in such a program. Personality traits have been shown to be a predictor for long-term mortality and complications in patients with chronic diseases. We assessed the personality traits neuroticism (NE), extraversion (EX), conscientiousness (CO), agreeableness (AG) and openness (OP) as well as resilience (RES) to explain therapy success or failure.

**Materials and methods:** We conducted a cross-sectional study of patients with T1DM and T2DM in a tertiary care centre in Germany during a period of three months. We assessed the short version of the Big Five Inventory (BFI-S), resilience scale (RS-13), treatment satisfaction (DTSQ standard) and social status in 669 patients (162 T1DM, age 52.17, duration of diabetes 20.05 years, HbA<sub>1c</sub> 7.51%, BMI 26.6 kg/m<sup>2</sup>, 507 T2DM, age 67.43, duration of diabetes 15.4 years, HbA<sub>1c</sub> 7.31%, BMI 32.9 kg/m<sup>2</sup>). Quality of diabetes care was measured by HbA<sub>1c</sub>, blood pressure, BMI and rates of serious and severe hypoglycaemia.

**Results:** In T2DM higher scores in CO are correlated with a lower mean HbA<sub>1c</sub>, R=-0.106[-0.504;-0.050], p<0.05. Personality traits or RES have no correlation to hypoglycaemia. Subgroup analysis of the highest and lowest scores of the personality traits showed that patients with higher scores in EX, OP and CO have a significantly (p<0.05) higher social status (EX 12.73 vs. 11.02 / OP 12.51 vs. 10.58 / CO 12.15 vs.10.46), less polyneuropathy, lower use of insulin (units/day) (EX 33.84 vs. 49.89 / OP 34.85 vs. 47.28 / CO 34.42 vs. 58.29), and higher scores for RES (EX 75.41 vs. 64.07 / OP 74.55 vs. 66.61 / CO 75.78 vs. 64.94) and lower scores for NE (EX 3.34 vs. 3.7 / OP 3.59 vs. 3.64 / CO 3.47 vs. 3.72). Patients with higher scores in NE have a higher BMI (35.27 vs. 32.69 kg/m<sup>2</sup>, p<0.05) and lower scores in EX, AG and RES (62.6 vs. 74.26, p<0.01). In T1DM no significant correlations could be identified comparing personality traits or RES and HbA<sub>1c</sub>, BMI and rates of hypoglycaemia. In subgroup analysis patients with higher scores in CO have a higher social status, 13.02 vs. 10.91, p<0.05, and patients with higher scores in NE have a lower social status, 11.5 vs. 13.6, p<0.05, and treatment satisfaction, 24.88 vs. 27.82, p<0.05. In both T1DM and T2DM higher scores in RES, and AG were positively correlated with the treatment satisfaction.

**Conclusion:** Apart from a weak correlation for CO and mean HbA<sub>1c</sub> in T2DM we found no significant influence of personality traits or RES on HbA<sub>1c</sub> and rates of hypoglycaemia. Higher RES and AG are positively associated with higher treatment satisfaction. Seemingly, psychic healthy persons are mostly sufficiently able to cope with diabetes related stress. It is known that participating in a structured treatment and education program equalised differences related to social status. A similar effect may occur with personality related differences as well.

## 953

**The ticking time bomb - fear of hypoglycaemia and its impact on diabetes control: baseline results from the ABACUS**K. Barnard<sup>1</sup>, D.A. Cavan<sup>2</sup>, R. Ziegler<sup>3</sup>, I. Cranston<sup>4</sup>, J. Ryder<sup>2</sup>, C. Vogel<sup>5</sup>, C.G. Parkin<sup>6</sup>, W. Koehler<sup>7</sup>, I. Vesper<sup>8</sup>, B. Petersen<sup>9</sup>, R.S. Wagner<sup>9</sup>;<sup>1</sup>University of Southampton, UK, <sup>2</sup>Royal Bournemouth Hospital, UK,<sup>3</sup>Diabetes Clinic for Children and Adolescents, Muenster, Germany, <sup>4</sup>QueenAlexandra Hospital, Portsmouth, UK, <sup>5</sup>Internistisches Facharztzentrum,Langen, Germany, <sup>6</sup>CGParkin Communications, Inc., Boulder City, USA,<sup>7</sup>baseline statistics GmbH, Mannheim, Germany, <sup>8</sup>Roche Diagnostics GmbH, Mannheim, Germany, <sup>9</sup>Roche Diagnostics, Inc., Indianapolis, USA.

**Background and aims:** Diabetes self-management is demanding and relentless, with prevalence of depression significantly higher for people with

both type 1 (T1DM) and type 2 (T2DM) diabetes. Fear of hypoglycaemia is a significant problem with a pervasive and detrimental effect on patients' abilities to self-manage their disease. However, such factors are not routinely addressed in clinical care, which can result in poor clinical and psychosocial outcomes. We explored the prevalence and impact of fear of hypoglycaemia in patients with poorly controlled diabetes.

**Materials and methods:** Baseline data were drawn from 116 subjects enrolled in the Automated Bolus Advisor Control and Usability Study (ABACUS), a large, prospective, randomised, multi-national study of poorly controlled ( $\text{HbA}_{1c} \geq 7.5\%$  /  $58 \text{ mmol/l}$ ), MDI-treated people with T1DM and T2DM. At screening, investigators administered the Hypoglycaemia Fear Survey (HFS-II), a validated measure of avoidance behaviours and worries specific to use of insulin.

**Results:** In this cohort with sub-optimal diabetes control, fear of hypoglycaemia was common, with 39.1% ( $n = 45$ ) of participants reporting that they "often" or "always" reduce their insulin dose to avoid hypoglycaemia; 34.2% ( $n = 39$ ) indicated that they performed self-monitoring of blood glucose (SMBG)  $\geq 6$  times per day as an avoidance strategy. Fear of hypoglycaemia within this population was correlated with increased problem areas in diabetes, higher mean blood glucose, increased depressive prevalence, and reduced diabetes treatment satisfaction. (Table 1)

**Conclusion:** These data suggest that fear of hypoglycaemia is highly prevalent and associated with poor glycaemic control and poor psychosocial health. These patients require management strategies that recognise and address this fear. Tools that minimise the risk of hypoglycaemia will likely increase confidence in achieving better control of diabetes; an automated bolus advisor may be one of those tools. This will be evaluated in the ABACUS.

Table 1. Correlation of fear of hypoglycaemia with other measures of clinical and psychosocial well-

Clinical/psychosocial measure	Correlation coefficients
Problem areas in diabetes	0.57
Mean blood glucose	0.39
Depressive disorders	0.35
Diabetes treatment satisfaction	-0.46

Clinical Trial Registration Number: NCT01460446

## 954

**Novel long-acting basal insulin analogue LY2605541 significantly reduces nocturnal hypoglycaemia and fear of hypoglycaemia compared to insulin glargine in patients with type 2 diabetes mellitus**

B. Curtis<sup>1</sup>, C. Shi<sup>2</sup>

<sup>1</sup>Global Health Outcomes, Eli Lilly and Company, Indianapolis, USA, <sup>2</sup>3 Statprobe, Detroit, USA.

**Background and aims:** The clinical impact of mild-moderate hypoglycemia (MH) is unclear. While physiologic manifestations are subtle, emotional impacts on the patient, reaction of the practitioner, and subsequent changes in their respective behaviors may lead to sub-optimal long-term outcomes. The aim of this analysis was to evaluate the impact of MH on patient behavior and fear of hypoglycemia using a validated patient-reported measure, the Adult Low Blood Sugar Survey (ALBSS).

**Materials and methods:** The basal insulin analog LY2605541 (LY) is a PE-Glylated insulin lispro designed to have a large hydrodynamic size which delays insulin absorption and reduces clearance, resulting in prolonged duration of action. In a 12-week, Phase 2, randomized, open-label, parallel study in patients with type 2 diabetes (T2DM), LY was compared to the basal insulin glargine (GL). The ALBSS is a patient-reported questionnaire, with items rated on a 5-point Likert scale (score 0-4) where a lower score indicates less impact of the item being measured. The behavior subscale has 15 items and the fear subscale 18 items. Patients completed the ALBSS at baseline, week 6, and week 12 of the study. Only patients who had baseline and at least 1 post-baseline measurement were included in the analyses. Treatment comparison was assessed using analysis of covariance (ANCOVA) model.

**Results:** At baseline (LY v GL) mean  $\pm$  SE FBG was  $8.16 \pm 0.17$  v  $7.77 \pm 0.22 \text{ mmol/L}$  and  $\text{HbA}_{1c}$  was  $7.7 \pm 0.1$  v  $7.8 \pm 0.1\%$ . At week 12, LY v GL resulted in similar mean fasting blood glucose ( $p = .433$ ) and mean  $\text{HbA}_{1c}$  ( $p = .279$ ) values. Intra-day blood glucose (BG) variability, as measured by

8-point self-monitored BG standard deviation, was reduced with LY ( $1.89 \pm 0.06$  v  $2.16 \pm 0.11 \text{ mmol/L}$ ,  $p = .031$ ). Adjusting for baseline nocturnal hypoglycemia, LY pts had a 48% rate reduction in nocturnal hypoglycemia events compared to GL ( $p = .021$ ). The mean scores of the behavior, fear, and total ALBSS score were not statistically different at baseline. The mean ALBSS fear score at week 12 was 6.6 (SD: 9.1) and 10.0 (SD: 15.8) for the LY and GL groups respectively, with an LS mean difference (LY-GL) of -2.3 (-4.0, -0.7 [ $p=.022$ ]). The mean ALBSS total score at week 12 was 13.0 (SD: 15.0) and 16.5 (SD: 22.5) for the LY and insulin GL groups respectively, with an LS mean difference (LY-GL) of -3.4 (-5.9, -0.9, [ $p=.026$ ]).

**Conclusion:** In patients with Type 2 diabetes, the novel long-acting basal insulin LY2605541 significantly reduced the baseline-adjusted rate of nocturnal hypoglycemia and patient fear of hypoglycemic events. The authors hypothesize that change in the ALBSS behavior sub-scale did not materialize due to the nature of a protocol-driven clinical trial, in which patients are more likely to comply with treatment recommendations. Further Phase 3 studies are underway to confirm these findings and to evaluate the impact on longer term health outcomes.

## 955

**GAPP2™: Global survey finds one in eight patients intentionally reduce basal insulin doses to avoid hypoglycaemia in the last month**

M. Brod<sup>1</sup>, M. Peyrot<sup>2</sup>, A. Rana<sup>3</sup>, A.H. Barnett<sup>4</sup>

<sup>1</sup>The Brod Group, Mill Valley, USA, <sup>2</sup>Sociology Department, Loyola University, Baltimore, USA, <sup>3</sup>Medical Affairs, Novo Nordisk, Copenhagen, Denmark, <sup>4</sup>Heart of England NHS Foundation Trust and University of Birmingham, UK.

**Background and aims:** There remain gaps in understanding about patient insulin-taking behaviour and why patients may miss doses. Questions about insulin-taking behaviour were therefore included in a large global survey (GAPP2™) of type 2 diabetes (T2DM) patients and healthcare professionals (HCPs) (primary care, diabetes specialists and diabetes nurses/educators) carried out to gain new insights into the challenges of insulin treatment and their impact on diabetes management.

**Materials and methods:** The survey was performed in six countries: USA, Canada, Japan, UK, Germany and Denmark. HCPs involved in diabetes management and T2DM patients (diagnosed at  $\geq 40$  years) receiving insulin treatment were identified from online research panels with over 6.5 million members.

**Results:** Data are presented on insulin-taking behaviour of 3042 T2DM patients using insulin analogue (IA), and experiences of 1653 HCPs. Patients reported irregular dosing of the basal insulin (BI). 48% had missed a dose, 51% had mis-timed by  $> 2$  hours and 38% had reduced a dose of BI. In the previous 30 days patients reported missing (22%: mean  $3 \pm 0.16$ ), mis-timing (24%: mean  $4.2 \pm 0.21$ ) or reducing (14%: mean  $4.2 \pm 0.24$ ) a dose of their BI. During this period, patients reported missing (17%), mis-timing (27%) or reducing (27%) their BI dose 5 times or more in a given month. This was greater than or approximately equivalent to the magnitude of dosing irregularities that HCPs reported as being significant enough to have a clinical impact on glucose control (for BI only patients:  $4.4 \pm 0.1$  missed,  $5.6 \pm 0.18$  mis-timed, or  $5.1 \pm 0.13$  reduced BI doses and for basal bolus patients:  $4.5 \pm 0.1$ ,  $5.6 \pm 0.18$ ,  $4.8 \pm 0.12$  respectively). On the last occasion that patients had missed, mis-timed or reduced their dose of BI, 13%, 17% and 77% respectively had done so intentionally. The most commonly cited reasons for this behaviour were low blood sugar levels and reduction in hypoglycaemia risk. Most patients recognised the clinical importance of irregular dosing. 63% of patients thought missing BI doses would have a negative impact on their long-term health and 37% reported they would feel guilty if they missed a BI dose. Only 10% of patients reported that they downplayed the number of missed doses to their HCPs, however, HCPs thought around 30% of patients downplayed missed doses.

**Conclusion:** Some patients intentionally dose their BI irregularly citing reduction in hypoglycaemia risk or low blood sugar as reasons for this behaviour. A proportion of patients undertake mis-dosing behaviour at a frequency that would be of concern to the HCPs despite an appreciation of the potential long-term consequences for their health. Further research is needed to focus on interventions which address the reasons for regular and intentional poor insulin-taking behaviour highlighted by our results.

Most common reasons for intentionally missing/mis-timing/reducing doses of basal insulin

	Missing a dose	Taking a dose > 2 hr earlier or later than prescribed	Reducing a dose
Total (n)	178	237	856
Blood sugar low	38%	21%	50%
Blood sugar high	7%	12%	3%
Reduced risk of hypoglycaemia	39%	22%	43%
Advised by a HCP	8%	3%	20%
Changed eating pattern	21%	30%	16%
Ran out/running low on insulin	17%	6%	9%
Skipped a meal	18%	14%	9%
Exercised recently	9%	8%	7%
Social situation	11%	20%	2%

### Assessing the relationship between the effect of glycaemic control and avoided symptomatic hypoglycaemia on quality of life in the management of type 2 diabetes

V. Foos<sup>1</sup>, P. McEwan<sup>2</sup>, A. Lloyd<sup>3</sup>, J. Palmer<sup>4</sup>, M. Lamotte<sup>5</sup>, D. Grant<sup>6</sup>;

<sup>1</sup>IMS Health, Basel, UK, <sup>2</sup>Swansea University, Swansea, UK, <sup>3</sup>IMS Consulting Group, London, UK, <sup>4</sup>IMS Health, Basel, Switzerland, <sup>5</sup>IMS HEOR, Vilvoorde, Belgium, <sup>6</sup>IMS Health, London, UK.

**Background and aims:** Achieving optimal blood glucose control minimizes long-term diabetes related complications. Hypoglycaemia represents a potential barrier to achieving optimal glycaemic control and also impacts directly on costs and health utility; furthermore, the hypoglycaemia profile of an intervention is potentially subject to less compound discounting if evaluated as an initial therapy. The objective of this study was to undertake an equilibrium analysis to identify the level of HbA<sub>1c</sub> reduction required to achieve the same quality of life benefit as achieved by avoiding events of non-severe symptomatic hypoglycemia (NSHE).

**Materials and methods:** This study used the Core Diabetes Model (CDM), a validated and established diabetes model, to explore the relationship between the avoidance of NSHE, HbA<sub>1c</sub> reduction and quality-adjusted life expectancy (QALE). Scenario analysis (SA) comparing typical therapeutic profile compared Treatment A versus Treatment B assuming 1) differential rates of NSHE ranging from 25 to 250 events per 100 patient years and no HbA<sub>1c</sub> effect and 2) an increasing difference in HbA<sub>1c</sub> ranging between 0.1% and 1% points (0.1% increments) with no effect on NSHE. The model was run over a lifetime and benefits were discounted at 3.0%. Patient baseline characteristics were based on NHANES population with a mean baseline A1c of 7.4%. Incremental QALE was observed using alternative assumptions for the disutility of symptomatic hypoglycemia based on published data (base case: -0.0052; SA: -0.0029, -0.0107, -0.0184).

**Results:** The relationship between rates of NSHE and incremental QALE was linear ( $R^2 > 0.9999$ ). The QALE gain associated with avoiding 1 NSHE per patient per year was 0.06; incremental QALE per event avoided changed in scenario analyses to 0.035, 0.124 and 0.212 quality adjusted life years for assumed disutilities of -0.0029, -0.0107 and -0.0184, respectively. The impact of HbA<sub>1c</sub> reduction on QALE gain ranged from 0.0112 to 0.1171 for changes between 0.1% and 1.0% points, respectively (also exhibiting a linear relationship;  $R^2 = 0.9922$ ). The HbA<sub>1c</sub> reduction required to achieve equivalent QALE benefit as the avoidance of one NSHE per patient per year was 0.54% in the base case analysis (NSHE disutility of -0.0052) and 0.33%, 1.08% and 1.84% in SA for NSHE disutilities of 0.0029, -0.0107 and -0.0184, respectively.

**Conclusion:** HbA<sub>1c</sub> change and reduced NSHE are key drivers when diabetes interventions are compared in cost effectiveness analyses. This analysis is noteworthy as it demonstrates the significant contribution to QALE exhibited by the avoidance of NSHE; particularly in comparison with levels of HbA<sub>1c</sub>

change typically associated current anti-hyperglycaemic agents. The avoidance of NSHE is at least as powerful a driver of QALE as lowering HbA<sub>1c</sub>.

## 957

### Health status in people with type 2 diabetes on basal-oral therapy is significantly improved with insulin degludec vs insulin glargine

J. Jendle<sup>1</sup>, N. Freemantle<sup>2</sup>, L. Meneghini<sup>3</sup>, T.E. Christensen<sup>4</sup>, M.L. Wolden<sup>4</sup>, R.E. Ratner<sup>5</sup>;

<sup>1</sup>Endocrine and Diabetes Center, University of Orebro, Sweden, <sup>2</sup>University College London, UK, <sup>3</sup>University of Miami Miller School of Medicine, USA, <sup>4</sup>Novo Nordisk, Søborg, Denmark, <sup>5</sup>MedStar Health Research Institute, Hyattville, USA.

**Background and aims:** Health status plays a critical role in therapy adherence in people with diabetes. Insulin degludec (IDeg) is a new-generation, ultra-long-acting basal insulin, forming soluble multi-hexamers following subcutaneous injection, achieving a stable time-action profile >24 hrs. This meta-analysis of patient level data from three open-label, randomised trials of 26 or 52 weeks duration compared the effect of IDeg and insulin glargine (IGlar) on health status in people with type 2 diabetes on basal-oral therapy.

**Materials and methods:** We assessed glycaemic control via HbA<sub>1c</sub> and fasting plasma glucose (FPG) concentrations, hypoglycaemia, defined as plasma glucose <3.1 mmol/L, and health-related quality of life, using the Medical Outcomes Study Short Form 36 (SF-36). Insulin-naïve patients received IDeg (n=1290) or IGlar (n=632) once daily, in combination with oral antidiabetic drugs. Statistical analysis was performed using a generalised linear model with treatment, trial, antidiabetic therapy at baseline, gender, region, age and relevant baseline values as explanatory variables.

**Results:** At baseline, mean age was 58.6 yrs, HbA<sub>1c</sub> 67 mmol/mol (8.3%), FPG 9.4 mmol/L and BMI 30.0 kg/m<sup>2</sup>. In all three trials, IDeg was confirmed as non-inferior to IGlar based on HbA<sub>1c</sub>. In each of the trials comprising the meta-analysis, FPG and confirmed overall and nocturnal (00:01-05:59 hrs) hypoglycaemia were all numerically or significantly lower with IDeg vs IGlar. At study end, overall physical component score was significantly higher (better) with IDeg vs IGlar (+0.66 [95% CI: 0.04; 1.28]), largely due to a difference (+1.10 [95% CI: 0.22; 1.98]) in the bodily pain domain score. In the mental domains, vitality was significantly higher with IDeg vs IGlar (+0.81 [95% CI: 0.01; 1.59]). The remaining SF-36 domains had scores in favour of IDeg, but were not significantly different between insulins.

**Conclusion:** Compared with IGlar, IDeg leads to improvements in both mental and physical health status for people with type 2 diabetes on basal-oral therapy.

## 958

### Binge-eating disorder in adults with newly diagnosed type 2 diabetes - baseline data from the SOUL-D study

H. Akram<sup>1</sup>, C. Kan<sup>1</sup>, S. Amiel<sup>2</sup>, K. Winkley<sup>1</sup>, K. Ismail<sup>1</sup>;

<sup>1</sup>Psychological Medicine, <sup>2</sup>Diabetes Research Group, Kings College London, UK.

**Background and aims:** The relationship between eating disorders and type 2 diabetes (T2DM) is poorly understood. The published prevalence of binge-eating disorder (BED) ranges from 1.4 to 25.6% among individuals with T2DM. The present study aims to ascertain the prevalence of BED among participants from the South London Diabetes (SOUL-D) Study and its impact on glycaemic control.

**Materials and methods:** SOUL-D is a community based prospective cohort study examining a range of biological, psychological and social factors in people with newly-diagnosed T2DM. The Eating Disorders Diagnostic Scale (EDDS) was used to screen for BED and the Patient Health Questionnaire (PHQ-9) for depression. BMI and HbA<sub>1c</sub> were also measured.

**Results:** From those who completed the EDDS questionnaire (n=1154), 20 reached full BED and 4 subthreshold BED diagnosis, representing 2.1% of the total sample. In comparison to subjects without BED, subjects with BED were significantly younger (mean(SD):50.9(12.6) vs. 55.8(11.5),  $p=0.032$ ), more likely to be female (83.3% vs. 42.3%,  $p<0.001$ ), in full-time employment (70.8% vs. 46.0%,  $p=0.016$ ) and less likely to be married (29.2% vs. 49.8%,  $p=0.046$ ). They also had higher BMI (37.9kg/m<sup>2</sup>(9.87) vs. 31.5kg/m<sup>2</sup>(6.3),  $p<0.001$ ), poorer glycaemic control (7.53%(1.56) vs. 6.97%(1.45),  $p=0.047$ ) and more depressive symptoms (9.27(7.34) vs. 4.23(5.22),  $p<0.001$ ).

**Conclusion:** There is a significant association between BED and worse metabolic and psychological outcomes in subjects with newly diagnosed T2DM. The finding underscores the relevance of assessing and addressing disordered eating behaviours in patients with T2DM, in order to improve biomedical and psychological outcomes.

## 959

### Does personality affect social status in patients with type 1 and type 2 diabetes?

F. Zillich<sup>1</sup>, W.C. Keweloh<sup>2</sup>, K. Wick<sup>1</sup>, N. Müller<sup>2</sup>, C. Kloos<sup>2</sup>, T. Lehmann<sup>3</sup>, G. Wolf<sup>2</sup>, U.A. Müller<sup>2</sup>;

<sup>1</sup>Institute of Psychosocial Medicine and Psychotherapy, <sup>2</sup>Endocrinology and Metabolic Diseases, Internal Medicine III, <sup>3</sup>Institute of Medical Statistics, Information Sciences and Documentation, University Hospital, Jena, Germany.

**Background and aims:** Patients with low social status showed worse HbA<sub>1c</sub> at the beginning of diabetes therapy in a tertiary care center but differences in therapy outcome related to social status were equalised while participating in structured therapy and education programs. We assessed personality traits neuroticism (NE), extraversion (EX), conscientiousness (CO), agreeableness (AG), openness (OP) as well as resilience (RES) as influencing factors on social status and therapy success or failure.

**Materials and methods:** We conducted a cross-sectional study of patients with type 1 (T1DM) and type 2 diabetes (T2DM) in a tertiary care centre in Germany during a period of three month. We assessed the short version of the Big Five Inventory (BFI-S), resilience scale (RS-13), treatment satisfaction (DTSQ standard) and social status in 669 patients (162 T1DM, age 52.17, duration of diabetes 20.05 years, HbA<sub>1c</sub> 7.51%, BMI 26.6 kg/m<sup>2</sup>, social status 12.67, 507 T2DM, age 67.43, duration of diabetes 15.4 years, HbA<sub>1c</sub> 7.31%, BMI 32.9 kg/m<sup>2</sup>, social status 11.65). Social status was measured by education level, highest professional position and household net income (total score 3–21). Quality of diabetes care was measured by HbA<sub>1c</sub>, blood pressure, BMI and rates of serious and severe hypoglycaemia.

**Results:** In T2DM differences in social status are causal for 5.8% of the differences in mean HbA<sub>1c</sub>.  $R=0.283$  [−0.081; 0.018],  $p<0.01$ . Higher social status goes along with higher scores for EX,  $R=0.347$  [0.277; 1.642];  $p<0.01$ , CO,  $R=0.434$  [0.058; 1.764],  $p<0.05$ , OP,  $R=0.422$  [0.986; 2.643],  $p<0.01$  and RES,  $r=0.172$ ,  $p<0.01$  and lower scores for NE,  $r=-0.102$ ,  $p<0.05$ . Subgroup analysis of the highest and lowest scores of the personality traits showed similar results. In T1DM higher social status are correlated to higher scores in OP,  $R=0.237$  [0.942; 4.305],  $p<0.01$  and lower scores in NE,  $R=-0.172$  [−2.655; 0.371],  $p<0.01$ . In subgroup analysis higher scores in CO were correlated to a higher social status, 13.02 vs. 10.91,  $p<0.05$  and significantly higher scores for RES, 75.02 vs. 61.48,  $p<0.01$  and EX, 3.22 vs. 2.86,  $p<0.01$ . Higher scores in NE are related to a lower social status, 11.5 vs. 13.6,  $p<0.05$  and to lower scores of RES, 73.45 vs. 62.71,  $p<0.01$ .

**Conclusion:** In both T1DM and T2DM higher social status means better therapy outcome. Higher social status is especially related to higher scores in conscientiousness and lower scores in neuroticism in T1DM and T2DM. Therefore people who are i.e. nervous, anxious, hostile, vulnerable or depressed might have lower social status when connected with treatment of diabetes. An association with depression or other psychiatric diseases should be examined. Resilience seems to correlate significantly with social status. Whether social status has significant influence on resilience or resilience influences social status remains to be clarified.

## 960

### Differences in social network and social support in people with type 1 and type 2 diabetes and the role of socioeconomic status

N.F. Hempler, L.E. Joensen, I. Willaing;

Steno Health Promotion Center, Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** A good social network and social support is associated with fewer psychosocial problems and better self-management behaviours in people with diabetes. People with type 1 and type 2 diabetes have different characteristics; however, little is known about differences in social network and social support in relation to diabetes type, and how socio-demographic factors might influence possible differences. We explored 1) differences in so-

cial network and social support between people with type 1 and type 2 diabetes and 2) whether differences were influenced by education level.

**Materials and methods:** We compared cross-sectional survey data from three populations: people with type 2 diabetes (N=1,084) and type 1 diabetes (N=2,426) from a specialist diabetes clinic and people with type 2 diabetes from a web panel (N=1,491). The web panel consisted of a representative sample of Danish people with type 2 diabetes and using the Internet. Social network was measured as contacts to friends and family, whereas social support was measured as the ability to get help from the social network in case of severe illness. All analyses were adjusted for age and cohabitation. Using logistic regression models we calculated the relative excess risk due to interaction (RERI), which indicates existing moderating effects of education.

**Results:** Our findings show that people with type 2 from the diabetes clinic (OR 2.01; 95% CI 1.57–2.59) and the web panel (OR 2.23; 95% CI 1.78–2.79) more often reported little contact with family, compared to people with type 1 diabetes. A similar pattern was observed regarding contact with friends. Furthermore, people with type 2 diabetes from the diabetes clinic (OR 1.44; 95% CI 1.44–2.08) and the web panel (OR 1.85; 95% CI 1.58–2.17) more often reported that they could not count on getting help in case of severe illness, compared with people with type 1 diabetes. The influence of education on social support and social network were more pronounced among people with type 2 compared to people with type 1. No notable differences were observed when analyses were stratified for sex.

**Conclusion:** In conclusion, people with type 2 diabetes have poorer social networks and less social support than people with type 1 diabetes. The findings indicate that differences in social network and social support to a larger extent were influenced by educational status in people with type 2 diabetes compared to people with type 1. Translating our findings into interventional practice, we suggest that interventions aiming at improving and establishing social relations and social support should be particularly emphasised in people with type 2 diabetes with low education.

## 961

### How do patients' preferences compare to the present spectrum of diabetes research?

S. Arnolds<sup>1</sup>, S. Heckermann<sup>1</sup>, P.T. Sawicki<sup>2</sup>;

<sup>1</sup>Profil Institute for Metabolic Research, Neuss, <sup>2</sup>Institute for Health Economics and Clinical Epidemiology, Medical Faculty of the University of Cologne, Germany.

**Background and aims:** It is unclear how current topics in diabetes research correspond to the research patients would like to see done. Thus, it was our aim to assess patients' preferences in diabetes research and compare them to the spectrum of scientific topics as presented during recent annual meetings of the European Association for the Study of Diabetes (EASD).

**Materials and methods:** Four experienced, scientifically active diabetologists divided the entire spectrum of diabetes research into nine main topics (table) - defined by consensus. The completeness of the proposed fields was checked by testing whether each and every abstract published during the EASD meeting in 2008 was covered by a defined scientific field. In order to obtain an as far as possible unselected sample of interested patients a questionnaire was published in a popular weekly news magazine, accompanied by an article inviting patients with diabetes and their relatives to express their preferences in diabetes research. They were asked to classify each of the nine prespecified scientific fields using a scale from 1 to 9 (1=least, 9=very important) and to decide which of the nine areas was of top priority. The status of the current spectrum of diabetes research was assessed by means of recent EASD abstracts. Two reviewers independently allocated all EASD abstracts published in 2010 and 2011 to one of the nine prespecified research fields. In case of disagreement a third reviewer was consulted.

**Results:** The main results are shown in the table. The questionnaire was answered by 652 patients with diabetes, 205 relatives and 61 other persons interested in the disease. The most important diabetes research fields from the patients' perspective were "development, pathophysiology and prevention of diabetes" (25.6%), "transplantation and cell therapy" (19.4%) and "blood glucose measurement and artificial pancreas" (16.5%), whereas "extreme blood values including hypoglycaemia and hyperglycaemia" was considered least important (2.4%). In 2010 and 2011 2645 EASD abstracts were published. The most often covered topic of current research was "development, pathophysiology and prevention of diabetes" (46.3%), followed by "diabetes complications in man" (17.5%), whereas "transplantation and cell therapy" had the lowest number of abstracts (0.7%).

**Conclusion:** The priorities and preferences of patients with diabetes and their relatives regarding the main diabetes research fields may differ when compared to current scientific activity. Institutions, sponsors and research foundations may consider involving patients with diabetes and their relatives more often in the weighting and selection of research topics.

Research preferences of survey participants versus EASD abstracts in 2010 and 2011

Field of research	Importance of research field* Mean score (SD) from 1=least important to 9=very important	Top priority field of research* n (%) of all responses	EASD 2010 + 2011 abstracts: assignment to field of research n (%)**	EASD 2010 + 2011 abstracts: Commercial sponsorship n (%)***
1) Development, pathophysiology and prevention of diabetes	8.14 (1.54)	235 (25.60)	1225 (46.31)	114 (9.31)
2) Transplantation and cell therapy	6.86 (2.36)	178 (19.39)	19 (0.72)	0 (0)
3) Non-pharmaceutical therapy	6.82 (2.53)	81 (8.82)	163 (6.17)	18 (11.04)
4) Insulin therapy	7.25 (2.08)	63 (6.86)	131 (4.95)	98 (74.81)
5) Blood-glucose lowering therapy without insulin	7.08 (2.36)	110 (11.98)	247 (9.34)	213 (86.23)
6) Extreme blood values including hypoglycaemia and hyperglycaemia	7.14 (2.08)	22 (2.40)	38 (1.44)	12 (31.58)

### Poor well-being and psychosocial risk factors among adolescents and young adults with diabetes: prevalence and association to metabolic control

K. Lange<sup>1</sup>, S. Enax<sup>1</sup>, K.-M. Röhlver<sup>2</sup>

<sup>1</sup>Medical Psychology, Hannover Medical School, Hannover,

<sup>2</sup>Diabeteszentrum, Christliches Krankenhaus, Quakenbrück, Germany.

**Background and aim:** Previous studies have suggested that psychological factors are important influences affecting the care and management of diabetes in adolescence. The study “Lebenschancen (life chances) with diabetes 2011” focuses on the prevalence of psychosocial risk factors, physical and psychosocial well-being and patients’ needs in the subsequent phases of transition to internal medicine and in young adulthood.

**Methods:** The participants of a diabetes camp for 16-25 year old people from all over Germany (CAMP D) were invited to fill in a questionnaire on their physical status (HbA1c, co morbidity, diabetes complication), emotional well-being (WHO-5 and HADS questionnaire) and diabetes related distress (PAID). In addition clinical and socioeconomic characteristics and satisfaction with main aspects of diabetes care (Likert scale: 1 optimal - 6 bad) were assessed.

**Results:** Data were received from 368 (91%) of the participants of CAMP D (64.5% female, mean age 20.2±2.6 y, mean diabetes duration 8.5±5.5 y, 45.7% CSII and 54.3% MDI). Late complications were diagnosed in 6.8% of the patients, but additional 13% didn’t know about it. 19.8% of the participants were affected by a second chronic disease (e. g. 2% asthma, 2% celiac, 8% hypo/hyperthyroidism). Mean HbA1c was 8.4±1.7% with 26% of the patients in insufficient control (HbA1c > 9%). While diabetes related distress (PAID) was rated low (22.9±14.5 (min 0 - max 80)), overall emotional well-being was severely impaired in 36.6% (WHO-5 sum score <13). 11% of participants showed (sub-) clinical symptoms of an anxiety disorder (HADS-A) and 4% symptoms of depression (HADS-D). 19.2% reported of former or current psychotherapy due to depression (10.1%), eating disorder (4.1%), anxiety (2.2%) or alcohol abuse (2.2%). In contrast to high satisfaction with medical care and diabetes education (mean scores: 2.1±1.1 / 2.3±1.3), satisfaction with psychosocial care was rated low (mean score: 3.0±1.5) by 230 participants. The remaining 35.8% young people stated that no psychosocial care was available. Emotional well-being (WHO-5) was associated with diabetes distress (r=-0.38), satisfaction with diabetes care (r=-0.25), gender (female < male), educational level (lower < higher) and family structure (parents living apart < living together). Participants with psychological co morbidity reported higher HbA1c than those without (9.1±1.9% vs. 8.2±1.6%) and lower well-being (12.5±4.7 vs. 14.3±5.0) (each p < 0.01). There was no association between type of insulin therapy (CSII or MDI) and HbA1c or emotional well-being (each p > 0.1).

**Conclusion:** More than 1/3 of the young people with diabetes reported of substantial impaired emotional well-being and 19% of former or current indication for psychotherapy. Psychosocial diabetes care was missed by more than a 1/3 of the young participants. On the background of the close association between metabolic control, emotional well-being, burden due to somatic and psychological co morbidities and psychosocial risk factors, better structures for integrated psychological screening and psychosocial care for young adults with diabetes are necessary.

## 963

### Adolescent girls with type 1 diabetes have poorer health perception and quality of life than the general population. A study in 18 countries on 95,870 adolescents

H.M.C. Hoey<sup>1</sup>, M. Trab Damsgaard<sup>2</sup>, P. Due<sup>2</sup>, C. de Beaufort<sup>3</sup>, H. Mortensen<sup>4</sup>, T.C. Skinner<sup>5</sup>, H.-J. Aanstoot<sup>6</sup>, L. Castano<sup>7</sup>, K.J. Robertson<sup>8</sup>, P. Swift On behalf of The Hvidoere Study Group<sup>9</sup>;

<sup>1</sup>Dept Paediatrics, University of Dublin, Trinity College, Ireland, <sup>2</sup>National Institute of Public Health, Copenhagen, Denmark, <sup>3</sup>Diabetes and Endocrine Care CP, Clinique Pédiatrique/CHL, Luxembourg, <sup>4</sup>E Herlev Hospital, Faculty of Health Science, Copenhagen, Denmark, <sup>5</sup>Rural Clinical School, Tasmania, Australia, <sup>6</sup>Diabetes Center for Paediatric and Adolescent Diabetes Care and Research, Rotterdam, Netherlands, <sup>7</sup>Hospital de Cruces, Bilbao, Spain, <sup>8</sup>Royal Hospital for Sick Children, Glasgow, UK, <sup>9</sup>Children's Hospital, Leicester Royal Infirmary, UK.

**Background and aims:** The Health Behaviour in School-Age Children study (HBSC) is a cross-national study, of 43 countries from Europe and North America and investigates health and health behaviour of adolescents. The Hvidoere Study Group (HSG) has shown that health perception and Quality of Life (QOL) of adolescents with type 1 diabetes (T1D) is poorer in girls than in boys and that good QOL and health perception are associated with better metabolic control. The aim of this study was to investigate whether QOL and health perception in adolescents with diabetes differs from their healthy peers.

**Materials and methods:** Adolescents aged 11, 13 and 15 years from 18 countries where data from both the HBSC and the HSG studies are available were studied (94,387 from the HBSC study and 1,483 with T1D from the HSG). Measures of QOL included life satisfaction (Cantril ladder) (score 0–10; high score indicates good life satisfaction) and health perception (rated excellent, good, fair or poor).

**Results:** Adolescents with diabetes particularly the older girls reported significantly poorer health perception than the general population and also lower than that of boys with diabetes. Health perception rated fair or poor - 11yrs: boys 10.7% vs HBSC 9.0% ( $p=0.056$ ), girls 18.7% vs HBSC 10.4% ( $p=0.0005$ ); -13 yrs: boys 21.3% vs HBSC 10.8% ( $p<0.0001$ ), girls 24.9% vs HBSC 15.6% ( $p<0.0001$ ); -15 yrs: boys 19% vs HBSC 12.1% ( $p=0.0006$ ), girls 35.69% vs HBSC 20.34% ( $p<0.0001$ ). Girls with diabetes reported less life satisfaction score by age than boys with T1D and also lower than that of the general population (HBSC): mean scores -11yrs: boys 8.08 vs HBSC 8.17, girls 7.74 vs HBSC 8.21; -13 yrs: boys 7.60 vs HBSC 7.83, girls 7.37 vs HBSC 7.56; and at 15 yrs boys 7.54 vs HBSC 7.52, girls 7.07 vs HBSC 7.17).

**Conclusion:** Adolescent girls with T1D have poorer health perception and QOL than their healthy peers. Good health perception and QOL are associated with better metabolic control and less perceived burden for the parents. Therefore good diabetic control should be promoted as a quality of life issue which should be audited yearly. Specific attention should be given to the management of adolescents with T1D, particularly girls, as they are very vulnerable and require additional resources.

### Self-reported chronic generic and diabetes-specific quality of life of 11- to 21-year olds with early-onset type 1 diabetes

A. Stahl<sup>1</sup>, K. Lange<sup>2</sup>, K. Straßburger<sup>1</sup>, K. Castillo<sup>1</sup>, C. Bächle<sup>1</sup>, T. Meissner<sup>3</sup>, R.W. Holl<sup>4</sup>, G. Giani<sup>1</sup>, J. Rosenbauer<sup>1</sup>, in cooperation with the German Pediatric Surveillance Unit (ESPED) and the DPV-Science initiative;

<sup>1</sup>Institute for Biometry and Epidemiology, German Diabetes Centre, Düsseldorf, <sup>2</sup>Medical Psychology Unit, Hannover Medical School, <sup>3</sup>University Hospital Düsseldorf, <sup>4</sup>Institute of Epidemiology and Medical Biometry, University of Ulm, Germany.

**Background and aims:** A major goal of diabetes care - especially in young patients with early-onset type 1 diabetes (T1DM) - is to achieve near-normal glycaemic control and unimpaired quality of life (QoL). This study aimed to analyse risk factors of impaired QoL in patients with early-onset T1DM and at least 10 years diabetes duration.

**Materials and methods:** Inclusion criteria for the nationwide questionnaire survey conducted in Germany 2009–2011 were T1DM onset occurring from 0 to 4 years of age during the years 1993–1999. QoL was assessed by means of the DISABKIDS self-report questionnaires: 12-item chronic generic module, diabetes-specific impact and treatment scales (scales 0–100, higher values

indicate better QoL). Analyses were performed with multivariable regression models. Results are reported as percentages, means and standard deviations (SD), or adjusted mean differences between groups (regression coefficients ( $\beta$ )) and standard errors (SE).

**Results:** Survey participants were 840 11- to 21-year olds with T1DM (50.6% boys, 16.3 (2.3) years of age, age at onset 3.0 (1.2) years, diabetes duration 13.3 (2.0) years, HbA1c 8.3 (1.4) %, 46.9% CSII). Poor glycaemic control was the strongest risk factor for impaired QoL (HbA1c  $>9.0$  vs.  $\leq 7.5$ :  $\beta_{\text{Generic}} = -9.1$  (1.5),  $\beta_{\text{Impact}} = -15.5$  (1.9),  $\beta_{\text{Treatment}} = -21.4$  (2.6), all  $p<0.001$ ; HbA1c  $>7.5\text{--}\leq 9.0$  vs.  $\leq 7.5$ :  $\beta_{\text{Generic}} = -5.7$  (1.2),  $\beta_{\text{Impact}} = -8.3$  (1.4),  $\beta_{\text{Treatment}} = -11.9$  (2.2), all  $p<0.001$ ) followed by impaired treatment satisfaction (poor vs. very good:  $\beta_{\text{Generic}} = -8.3$  (1.7),  $\beta_{\text{Impact}} = -9.2$  (2.0),  $\beta_{\text{Treatment}} = -14.9$  (2.9), all  $p<0.001$ ; good vs. very good:  $\beta_{\text{Generic}} = -2.7$  (1.2),  $\beta_{\text{Impact}} = -3.6$  (1.5),  $\beta_{\text{Treatment}} = -6.4$  (2.1), all  $p<0.05$ ). Hypoglycaemia during the last 12 months and therapy without CSII were also associated with impaired QoL (hypoglycaemia last month or week vs. never:  $\beta_{\text{Generic}} = -4.4$  (1.4),  $\beta_{\text{Impact}} = -3.8$  (1.7),  $\beta_{\text{Treatment}} = -6.5$  (2.4), all  $p<0.05$ ; CSII no vs. yes:  $\beta_{\text{Generic}} = -3.6$  (1.1),  $\beta_{\text{Impact}} = -5.2$  (1.3),  $\beta_{\text{Treatment}} = -4.9$  (1.9), all  $p<0.01$ ). Lower socio-economic status was associated with lower scores on two scales (low and middle vs. high:  $\beta_{\text{Generic}} = -4.0$  (1.1),  $\beta_{\text{Impact}} = -3.7$  (1.4), all  $p<0.01$ ). Overweight status and prior hospitalisation were each associated with poorer scores on one scale (overweight vs. under- and normal weight:  $\beta_{\text{Impact}} = -6.1$  (1.8),  $p=0.001$ ; hospitalisation during last 12 months yes vs. no:  $\beta_{\text{Generic}} = -3.1$  (1.3),  $p=0.017$ ). Older age was associated with better ratings on the impact scale (18–21y / 14–17y vs. 11–13y:  $\beta_{\text{Impact}} = 7.1$  (2.0) / 4.9 (1.7), all  $p<0.01$ ). Gender was not associated with QoL.

**Conclusion:** The results underline the close relationship between QoL and therapy (including treatment satisfaction, metabolic control, therapeutic regimen and hypoglycaemic episodes) among children, adolescents and young adults with early-onset and long duration T1DM.

## 965

### The impact of type 2 diabetes on emotional state and quality of life

J. Ceponis<sup>1</sup>, L. Lasaitis<sup>2</sup>;

<sup>1</sup>Department of Endocrinology, <sup>2</sup>Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania.

**Background and aims:** The aim of the study was to analyze the impact of the course of disease on emotional state and quality of life (QoL) in patients with type 2 diabetes mellitus (T2DM) and outline possible gender-specific differences.

**Materials and methods:** A total of 218 patients (118 women and 100 men), aged 40–78 (mean  $59.5\pm 9.4$  years) were asked to complete Profile of Mood State (POMS) and WHO BREF Quality of Life (QoL) questionnaires. Data were grouped by diabetes duration (under 5 years, 5–10 years,  $>10$  years), quality of glucose control (HbA1c values of  $<6.5\%$ ,  $6.5\text{--}8\%$ , and  $>8\%$ ) and number of complications (0, 1,  $\geq 2$ ). Values were analyzed for both genders separately and results were compared.

**Results:** The 5–10 yrs. T2DM duration group demonstrated the most favorable POMS and QoL scores, however significance was only reached in women in POMS fatigue-inertia ( $9.6\pm 4.7$ ;  $5.9\pm 4.5$ ;  $8.1\pm 5.7$  for each group,  $p=0.006$ ) and confusion-bewilderment domains ( $3.8\pm 3.7$ ;  $1.3\pm 3.5$ ;  $3.1\pm 3.4$ ,  $p=0.004$ ), and QoL social relationships domain ( $13.0\pm 3.0$ ;  $14.6\pm 1.8$ ;  $13.9\pm 1.9$ ,  $p=0.031$ ). Inter-gender differences were observed in all groups, and were most pronounced during the first 5 years of the disease; men demonstrated significantly better scores across all domains with a notable exception of the POMS anger-hostility domain. The scores in the latter in men were higher throughout, reaching statistical significance in 5–10 years disease duration group ( $p=0.026$ ). An association of better QoL scores with higher HbA1c was observed and was significant in the social relationships domain in women ( $12.1\pm 3.2$ ;  $14.0\pm 2.1$ ;  $14.3\pm 1.9$ , respectively,  $p=0.024$ ). Gender differences were most marked in POMS vigor-activity and QoL environmental domains in the lower HbA1c range, and in QoL psychological domain in the higher HbA1c range. An association of increasing number of complications with lower QoL was significant in QoL psychological domain in women ( $12.3\pm 2.7$ ;  $12.1\pm 1.6$ ;  $13.7\pm 2.4$ ,  $p=0.016$ ) and in QoL physical domain in men ( $14.7\pm 1.9$ ;  $13.3\pm 2.5$ ;  $10.6\pm 0.4$ ,  $p=0.028$ ). The inter-gender differences were most marked in the complication-free group where women showed significantly worse results in POMS depression-dejection ( $p=0.010$ ), fatigue-inertia ( $p=0.008$ ), confusion-bewilderment ( $p=0.043$ ) domains, and in QoL physical ( $p<0.001$ ), psychological ( $p=0.001$ ) and environmental ( $p=0.035$ ) domains.

**Conclusion:** Quality of life and emotional status were best in patients with intermediate duration of T2DM; social aspects of QoL tended to improve

with an increasing HbA1c, possibly due to low cut-off values in HbA1c categories. Decreased QoL, as determined by scores in physical and psychological QoL domains, was significantly associated with increasing number of complications. The study found significant inter-gender differences in emotional status and quality of life scores; the differences in specific domains were most likely due to different strategies in coping with the disease.

## 966

### Differences in patient and clinician perspectives on type 2 diabetes mellitus management: the MOTIVATE global survey

P.E.H. Schwarz<sup>1</sup>, A.M. Felton<sup>2</sup>, M. Cobble<sup>3</sup>, S. Cavalcanti da Silva<sup>4</sup>, Y. Seino<sup>5</sup>, J. Wens<sup>6</sup>;

<sup>1</sup>Department of Medicine III, Technical University of Dresden, Germany, <sup>2</sup>FEND, London, UK, <sup>3</sup>Canyons Medical Center, Univ of Utah, Sandy, USA, <sup>4</sup>Endocrinology and metabolism, Santa casa de belo horizonte, Belo horizonte, Brazil, <sup>5</sup>Clinical Nutrition and Endocrinology, Kansai Electric Power Hospital, Osaka, Japan, <sup>6</sup>Primary and Interdisciplinary Care, University of Antwerp, Belgium.

**Background and aims:** Despite many therapeutic options and established treatment goals for patients with type 2 diabetes mellitus (T2DM), attaining combined goals for hyperglycaemia, weight reduction, blood pressure and dyslipidaemia remains difficult. The Measuring Opinions of Treatment Interventions In type 2 diAbetes mEllitus (MOTIVATE) global survey aims to improve understanding of the and differences in the perceptions of clinicians and patients regarding the treatment for T2DM.

**Materials and methods:** The MOTIVATE global survey assessed the perceptions that patients and primary care clinicians have on diabetes management beyond hyperglycaemia and evaluated weight management as a possible motivator of patient self-management. The MOTIVATE survey was an internet-based, 10-item questionnaire posed to patients with T2DM (n=2140) and clinicians (n=1406) randomly selected from 13 countries (US, Europe, Canada, China, Australia, Brazil, Mexico, Japan and South Africa) regarding attainment of various therapeutic goals and clinicians' understanding of their patients' anxiousness regarding these goals. Difference of  $\geq 3\%$  = statistically significant [95% CI], and  $\geq 10\%$  = clinically meaningful.

**Results:** Approximately 95% of patients and clinicians perceived the need for medications that address challenges beyond hyperglycaemia. Sixty percent of patients rated diabetic complications as one of their top three anxiety-provoking concerns while clinicians estimated that only 43% of their patients felt this way. Half of patients (52%) identified weight loss of  $>10\%$  as being meaningful while half of clinicians (51%) reported 1–5% weight loss as being meaningful; clinicians placed greater emphasis on durability of weight loss. Patients were more anxious about their blood pressure and lipid levels (19% and 18% reported as being very anxious, respectively) than clinicians perceived them to be (5% and 4%, respectively). Both patients and clinicians prefer a medication that offers modest weight loss (2.5%) even if accompanied by their least acceptable side effect. Patients and clinicians reported dizziness / fainting / hypoglycaemia as the least acceptable side effects.

**Conclusion:** The MOTIVATE global survey highlighted substantial disconnects between the perceptions of clinicians and patients regarding medication and therapeutic goals. These differences may impact the ability to attain desired T2DM treatment goals.

### GAPP2™: Global survey finds that a quarter of Japanese type 2 diabetes downplay insulin non-adherence to their healthcare professional

Y. Atsumi<sup>1</sup>, M. Brod<sup>2</sup>, A.H. Barnett<sup>3</sup>, M. Peyrot<sup>4</sup>;

<sup>1</sup>Saiseikai Central Hospital, Tokyo, Japan, <sup>2</sup>The Brod Group, Mill Valley, USA, <sup>3</sup>Heart of England NHS Foundation Trust and University of Birmingham, Birmingham, UK, <sup>4</sup>Loyola University, Baltimore, USA.

**Background and aims:** Type 2 diabetes (T2DM) rates are increasing in Japan due to a mix of genetic and environmental factors. Insulin analogue (IA) is widely initiated at diagnosis in Japan and a paternal physician-patient relationship remains common. To understand the impact of these issues, Japanese (JP) T2DM patients using IA and healthcare professionals (HCPs) were included in the GAPP2™ survey to assess the challenge of insulin irregularities and gain insights into differences between JP and other countries.

**Materials and methods:** An internet survey was carried out in US, Canada, Japan, UK, Germany and Denmark. HCPs involved in diabetes management and T2DM patients were identified from online research panels with over 6.5 million members. Data from 355 JP IA patients and 231 JP HCPs is compared with 2687 patients and 1422 HCPs from the five other survey countries (GP2).

**Results:** Although lower than other countries, JP patients reported irregularities of basal insulin (BI). In the last 30 days, 15% of JP patients reported missing doses of BI (mean 3.1 times) and 20% had missed 5+ doses (GP2, 22%; mean 3: 16% 5+ doses missed). JP HCPs said BI only patients told them they missed 1.5 doses per month (1.1 basal bolus patients (BB)), with just 11% admitting to 5+ missed BI doses (7% BB). GP2 HCPs reported higher numbers, mean 2.9 doses BI only (2.6 BB) and 21% missing 5+ doses (19% BB). In the same time period, 18% of JP patients reported mis-timing by  $> 2$  h (mean 5.4 times, 45% mis-timed 5+ doses), and 11% reducing a dose of BI (mean 3.8 times, 32% 5+ doses) compared to 25% (mean 4.1, 25% 5+ doses) and 15% (mean 4.2, 26% 5+ doses) for GP2 patients respectively. JP HCPs said that patients reported a significantly lower mean number of mis-timed and reduced BI doses (including those mis-timing/reducing 5+ doses) than GP2 HCPs. On the last occasion that JP patients had missed, mis-timed or reduced their BI dose, 15%, 15% and 69% had done so intentionally (13%, 17%, 77% of GP2 patients). For all patients the most common reasons for this were low blood sugar levels and hypoglycaemia risk reduction. 49% of JP patients (65% GP2) thought that missed BI doses would negatively impact their long-term health. However, more JP patients (55% vs 35% GP2) reported they would feel guilty if they missed a BI dose and JP patients were more likely to downplay the number of missed BI doses to their HCPs than GP2 respondents (22% vs 9%).

**Conclusion:** JP T2DM patients report substantial irregularities of BI dose which may lead to glycaemic control issues and long-term complications. Differences in reported rates compared to the GP2 IA population may be due to under-reporting, the impact of earlier insulin initiation or may reflect cultural differences in medication adherence. Cultural issues around reporting “failure” to HCPs require further study.

### Basal insulin injection non-adherence reported by T2DM patients using IA

	Missed BI dose		BI dose taken $> 2$ hrs earlier or $> 2$ hrs later than prescribed		Reduced BI dose

### Evaluation of the personality characteristics of type 1 patients in CSII therapy

A. Girelli<sup>1</sup>, D. Bruttomesso<sup>2</sup>, S. Ciaccio<sup>1</sup>, G. Grassi<sup>3</sup>, E. Cimino<sup>1</sup>, S. Costa<sup>2</sup>, A. Nicolucci<sup>4</sup>, R. Scotton<sup>2</sup>, U. Valentini<sup>1</sup>;

<sup>1</sup>Diabetes Care Unit, AO Spedali Civili, Brescia, <sup>2</sup>Diabetes Care Unit, AO University of Padova, <sup>3</sup>Division of Endocrinology, S. Giovanni Battista Hospital, Torino, <sup>4</sup>Mario Negri Sud, S. Maria Imbaro, Chieti, Italy.

**Background and aims:** The success of CSII (continuous subcutaneous insulin infusion) depends on the patient's proficiency and motivation. Few studies

have examined how personality influences the outcome of CSII. Aim of this multi-centric, observational, cross-sectional study was to describe the clinical and psychological characteristics of a large cohort of patients with type 1 diabetes treated with CSII and compare them with a group of patients treated with multiple daily insulin injections (MDI). We also studied the relationship between psychological characteristics and the effectiveness of therapy.

**Materials and methods:** 361 type 1 diabetic patients were sequentially recruited: 185 on CSII (61M / F124; disease duration  $20 \pm 10$  (SD) years; on CSII for  $5 \pm 4$  years) and 176 patients on MDI (M76 / F100; disease duration  $17 \pm 10$  years). Personality traits were assessed through validated questionnaires (BFQ-Big Five Questionnaire, Multidimensional Health Questionnaire-MHQ).

**Results:** Female patients were more numerous among patients on CSII. Considering metabolic control, glycated emoglobin levels were similar in the two groups (CSII= $7.8\% \pm 0.9$ , MDI= $7.7\% \pm 1.0$ ), but CHO counting was used more frequently ( $p=0.000$ ), and severe hypoglycemia was lower ( $p=0.032$ ) among patients on CSII. Patients in CSII showed significantly higher scores in the following domains: dynamism ( $p=0.050$ ), agreeableness ( $p=0.007$ ), friendliness ( $p=0.026$ ), openness to experience ( $p=0.011$ ), Health Efficacy ( $p=0.028$ ). Among CSII patients, those in better control ( $<7.5\%$ ) resulted have a higher score for conscientiousness ( $p=0.019$ ), Health-Efficacy ( $p=0.002$ ), Health Expectations-Optimism ( $p=0.034$ ), Health Esteem ( $p=0.0001$ ), Health Satisfaction ( $p=0.001$ ), Health Self-Schemata ( $p=0.036$ ) and Health Status ( $p=0.001$ ). Patients with poor control (HbA1c  $> 8.5\%$ ) showed higher scores for Health Anxiety ( $p=0.010$ ), Health Illness Self-Blame ( $p=0.024$ ), Health Monitoring ( $p=0.042$ ) and Health Depression ( $p=0.008$ ). When comparing CSII vs. MDI patients within the HbA1c  $<7.5\%$  range, CSII patients achieved average scores significantly higher on scales cooperativeness ( $p=0.013$ ), friendliness ( $p=0.024$ ), impulse control ( $p=0.033$ ), Health-Efficacy ( $p=0.009$ ), Health Consciousness ( $p=0.006$ ), Health Expectations-Optimism ( $p=0.044$ ), Illness Management ( $p=0.013$ ), Health Esteem ( $p=0.001$ ), Health Satisfaction ( $p=0.037$ ). Considering patients on CSII and MDI with HbA1c between 7.5–8.5%, those on CSII showed greater scores on scales openness to experience ( $p<0.009$ ) and Health-Efficacy ( $p<0.048$ ). There was no difference between CSII and MDI when HbA1c was above 8.5%.

**Conclusion:** Patients on CSII are more active and have a greater sense of self-efficacy than those in MDI. In patients on CSII, metabolic control is better in patients who are more conscientious, active, optimistic, have higher self-esteem and satisfaction with health status. This analysis confirms that psychological characteristics can significantly influence the success of CSII therapy and should be evaluated in the selection of patients.

**Results:** A 1 point lower score on the PF, GH, and PCS scales was associated with a 1.05–1.10 RR of mortality for the DM patients. The associations showed age dependence for these scales, with stronger associations in the younger age groups. For several scales (PF, RP, BP, GH, VT, SF, and RE), the associations with mortality also depended on score level, with stronger associations in the lower score ranges (i.e. among patients in worse health). A 1 point lower score on the PF, RP, BP, GH, SF, and PCS scales implied a 1.07–1.11 RR of being unable to work and a 1.05–1.06 RR of losing the ability to work. These associations were dependent on score level, with stronger associations in the higher score ranges. A 1 point lower score on the PF, RP, BP, GH, SF, and PCS scales was associated with a 1.03–1.04 RR of hospitalization. When baseline score and age were taken into account for each outcome, the results from the total sample did not differ significantly from the DM patients' results. Gender, education, marital status, and comorbidity score had only a minor impact on the strength of any of the associations.

**Conclusion:** Statistical associations with outcomes such as mortality, work ability, and risk of hospitalization can be used as benchmarks to interpret the magnitude of scale score differences for PROs. For a diabetes population, the results indicate up to 10% excess risk of mortality and inability to work for a 1 point lower score on selected SF-36 scales.

### Benchmarks for interpretation of score differences on the SF-36 health survey for diabetes patients

J.B. Bjorner<sup>1,2</sup>, M.L. Wolden<sup>3</sup>, J. Gundgaard<sup>3</sup>, K. Miller<sup>1</sup>;

<sup>1</sup>QualityMetric, Lincoln, USA, <sup>2</sup>Department of Public Health, University of Copenhagen, <sup>3</sup>Novo Nordisk, Copenhagen, Denmark.

**Background and aims:** Patient-reported outcomes (PROs) are widely used in clinical research. However, results on score differences may be hard to interpret if clinicians are unfamiliar with the assessment tools and lack benchmarks for interpretation of results. This study aims to establish an interpretation of score differences on the SF-36 Health Survey by linking score differences to clinical and social outcomes, and to apply this interpretation model to a diabetes mellitus (DM) population. Further, it tests whether the interpretation depends on score level and patient background characteristics.

**Materials and methods:** Using survival and logistic regression models, data from the following 3 large US cohort studies was reanalysed: the Medical Outcomes Study (N=3,445; 541 DM patients), the Medicare Health Outcomes Study (N=78,183; 16,388 DM patients), and the QualityMetric 2009 Norming Study (N=4,040; 580 DM patients). Outcome variables were mortality, hospitalization within 6 months after baseline, inability to work at baseline, and loss of ability to work within 6 months after baseline. The independent variables included scale score, age, gender, education, marital status, and number of comorbidities. Separate analyses tested scales concerning Physical Function (PF), Role Limitation due to Physical Health (RP), Bodily Pain (BP), General Health (GH), Vitality (VT), Social Function (SF), Role Limitation due to Emotional Problems (RE), Mental Health (MH), the Physical Component Summary (PCS), and the Mental Component Summary (MCS). Regression models from the total samples were applied to the DM patients and the estimated relative risks (RR) were compared to the results of separate analyses for the DM patients.

## PS 080 Psychological aspects: stress and depression

970

### Depressive symptoms in type 1 diabetic children with poor and excellent metabolic control

B.M. Zdunczyk<sup>1</sup>, J. Sendela<sup>2</sup>, H. Trippenbach-Dulska<sup>3</sup>, M. Lipka<sup>2</sup>, M. Procter-Czaplinska<sup>2</sup>, L. Groele<sup>2</sup>, A. Szybowska<sup>3</sup>;

<sup>1</sup>Clinical Child and Adolescent, Clinical Pediatric Hospital, <sup>2</sup>The Department of Pediatrics, Clinical Pediatric Hospital, <sup>3</sup>Department of Pediatrics, Medical University of Warsaw, Poland.

**Background and aims:** Many studies show there is a higher incidence of diabetes among patients with depression and depression is more often diagnosed in patients with diabetes than in healthy population. Depression is considered a major complication negatively affecting metabolic control in patients with diabetes. The aim of this study was to assess the prevalence of depression and examine its effect on metabolic control and quality of life in children and adolescents with diabetes type 1.

**Materials and methods:** 477 children took part in this study: 252 girls and 225 boys with diabetes duration > 1 year. Mean age: 13.1 years <7–17, SD 2.7>. Mean diabetes duration: 5 SD 3.5 years, mean HbA1c 7.5% <5–13.9, SD 1.5>. During the routine visit in the outpatient clinic all children and adolescents with diabetes type 1 age 7 and above were asked to fill in Polish version of Children's Depression Inventory by M. Kovac, a self-report questionnaire consisting of 27 items. Patients from age 11 and above were additionally asked to answer questions in 58-item Quality of Life Questionnaire, based on the DCCT Diabetes Quality of Life Measure. At the same time other data was collected: sex, age, diabetes duration, HbA1c, BMI, daily insulin dose.

**Results:** 17% (81/477) participants scored  $\geq 13$ , indicating elevated depressive symptoms. We found significant relationship between scores on CDI and HbA1c ( $r=0.16$ ,  $p=0.0002$ ). 181/477 (38%) children achieved mean HbA1c  $\leq 7\%$ , in this group 13% (24) subjects had CDI  $\geq 13$ . There was no difference between the frequency of depressive symptoms in children with HbA1c  $\leq 7\%$  ( $p=0.102$ ). We also didn't find the difference between participants with CDI  $\geq 13$  and CDI < 13 in HbA1c ( $p=0.24$ ). There was an extremely significant correlation between scores on the CDI and quality of life ( $r=0.64$ ,  $p<0.0001$ ), age of participants ( $r=0.24$ ,  $p<0.0001$ ) and BMI ( $r=0.22$ ,  $p<0.0001$ ). We found the difference between children with CDI  $\geq 13$  and CDI < 13 in BMI ( $p=0.0293$ ). There was also a significant correlation between scores in the CDI and insulin daily dose ( $r=0.10$ ,  $p=0.0229$ ). In the group with HbA1c  $\leq 7\%$  children with CDI  $\geq 13$  and CDI < 13 didn't differ in BMI or daily insulin dose. 9.8% (47) participants reported suicidal thoughts, which have a significant impact on CDI scores ( $P<0.0001$ ) and quality of life ( $P<0.0001$ ) but not on HbA1c ( $P=0.1106$ ). There was no difference between girls and boys on the CDI scores.

**Conclusion:** 17% participants show elevated depressive symptoms as assessed with Children's Depression Inventory. Children and adolescents with higher scores on the CDI are older, have worse quality of life, higher BMI, daily insulin dose as well as achieve worse metabolic control. Still they achieve similar level of HbA1c as their peers with lower CDI scores. Depressive symptoms were noted in 13% children with excellent control of diabetes (HbA1c  $\leq 7\%$ ). It is necessary to pay attention to emotional wellbeing of children and adolescents with diabetes type 1 regardless of HbA1c. An intervention program aimed at prevention of emotional problems in youths with diabetes should be developed. Depressive symptoms may be no more a major factor in adherence to treatment but more studies are required.

971

### The assessment of factors determining fatigue in subjects with long history of type 1 diabetes

A. Duda-Sobczak, D. Zozulinska-Ziolkiewicz, B. Wierusz-Wysocka; Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland.

**Background and aims:** Type 1 diabetes is a chronic disease requiring continuous insulin therapy. Adjusting the rules of treatment to the existing lifestyle can be a source of emotional distress and the feeling of fatigue. The aim of this study was to assess the factors determining the fatigue in subjects with long history of type 1 diabetes.

**Materials and methods:** 213 subjects (116 women), aged <60 years (26.6

$\pm 6.0$ ), diabetes duration >20 years ( $42.2 \pm 10.5$ ), HbA1c  $8.2 \pm 1.4\%$  ( $66 \pm 7.0$  mmol/mol) were included. Subjects diagnosed with chronic complications causing disability (blindness, end stage renal disease, painful peripheral neuropathy, limb amputation) were excluded. Patients fulfilled questionnaire comprising the question: Do you feel fatigue due to living with diabetes? Additionally, Problem Areas in Diabetes Questionnaire (PAID), Beck Depression Inventory (BDI), NEO-FFI (Neuroticism-Extraversion-Openness Five Factor Inventory) were completed. Socioeconomic status and parameters of metabolic control were assessed.

**Results:** 57% of subjects (61% of women, 51% of men) declared fatigue due to diabetes. Economically active people were less tired of disease ( $p=0.001$ ), subjects with higher education level less frequently declared fatigue ( $p=0.03$ ). The fear of hypoglycemia was more frequent in group declaring fatigue due to diabetes ( $p=0.001$ ).

**Conclusion:** Fatigue in type 1 diabetes is determined by comorbid depressive disorder, difficulty coping with diabetes, neurotic personality and some socioeconomic factors.

### Characteristics of group declaring and denying fatigue due to diabetes

	Declared fatigue due to living with diabetes		P
	yes	no

### The triple P study: psychopathology in pump patients

P.S. Grant;

Diabetes & Endocrinology, Tunbridge Wells Hospital, Pembury, UK.

**Background and aims:** CSII is generally successful for patients with type 1 diabetes in improving glycaemic control, alleviating the burden of hypoglycaemia and improving quality of life. There is however, a cohort of patients who fail to thrive on pump therapy and psychological factors or 'brittleness' have been posited as a cause for this. We aimed to assess the extent and spectrum of psychological illness in a population of pump patients.

**Materials and methods:** We analysed the patient data and records of 350 patients with type 1 diabetes who formed the insulin pump patient population from a large teaching hospital and compared them with an age and sex matched reference population of patients with type 1 diabetes. We quantified the prevalence of mental health problems both before and after the initiation of pump therapy and looked to see whether there was a difference in terms of changes in glycaemic control.

**Results:** In this analysis, it appears that mental health problems amongst patients selected for CSII occur significantly more frequently than in a matched population of type 1 diabetics. Of those with psycho-pathology, they have a tendency to do less well in terms of reduction in glycaemic control as indicated by changes in HbA1c, however hypoglycaemia incidence did not appear to differ significantly either.

**Conclusion:** The incidence and prevalence of mental health problems in individuals with diabetes is greater than that of the general population. In patients who go on to be selected to have insulin pump therapy, the incidence is again greater. We have shown that in those with psychological illness they tend to do less well in terms of improving their overall diabetes control, with some patients even doing worse than before. These results show that CSII may not be a suitable route of therapy for all of those who would fulfill the traditional criteria and suggest that psychological assessment, therapy and intervention may be an altogether more appropriate course of action in supporting their diabetes self management. The wider implications are that all patients with diabetes should be regularly assessed for psychological problems and that there needs to be greater psychology / psychiatric support available to diabetes clinics.

## 973

**The diabetes education program affects the depression score of type 2 diabetic patients**

T. Niya<sup>1</sup>, S. Furukawa<sup>1,2</sup>, Y. Tamagawa<sup>1</sup>, S. Shojima<sup>1</sup>, K. Manabe<sup>1</sup>, A. Ogawa<sup>1</sup>, E. Kawamoto<sup>1</sup>, T. Ueda<sup>3</sup>, H. Tokunaga<sup>3</sup>, O. Ebisui<sup>3</sup>;

<sup>1</sup>Department of Internal Medicine (Diabetes & Endocrinology), Matsuyama Shimon Hospital, <sup>2</sup>Department of Gastroenterology and Metabolism, Ehime University Graduate School of Medicine, Toon,

<sup>3</sup>Department of Diabetes & Endocrinology, Ehime Prefectural Central Hospital, Matsuyama, Japan.

**Background and aims:** Recently, many reports have shown that depressive symptoms in type 2 diabetic patients are linked with hyperglycaemia and many other diabetic complications. Treatment of diabetes may affect the depressive symptoms in patients with type 2 diabetes. In addition, when the patients understand their prognosis with regard to diabetic complications, they may feel depressed. Thus, while performing the diabetes education program for type 2 diabetic patients, it is necessary to be careful about depressive symptoms. The aim of this study was to investigate the effect of a diabetes education program on depressive symptoms.

**Materials and methods:** We enrolled 528 patients with type 2 diabetes who were admitted to our hospital to participate in the diabetes education program [age:  $60.8 \pm 11.1$  years, M/F: 330/198, HbA1c level:  $9.7\% \pm 1.8\%$ ]. We evaluated their depressive symptoms using the Zung Self-Rating Depression Scale (SDS) before and after the diabetes education program. In the program, we managed to achieve glycaemic control; in addition, we detected the presence of diabetic complications and performed self-management education for 2 weeks during hospitalization. We investigated the changes in the SDS score and the scores of 3 sub-scales (pervasive effects, physiological equivalents, and psychological equivalents) before and after the diabetes education program. Statistical evaluation was performed using a Wilcoxon signed-rank test. The level of significance was set at  $P < 0.05$ .

**Results:** Before we performed the diabetes education program, the number of diabetic patients in a non-depressive state was only 232 (43.9%). There were 167 (31.6%) and 129 (24.4%) diabetic patients in mild and moderate/severe depressive state, respectively. The SDS score decreased significantly in all patients in a depressive state ( $40.6 \pm 8.9$  to  $39.7 \pm 9.0$ ,  $P = 0.0025$ ); it decreased from  $43.4 \pm 2.3$  to  $41.3 \pm 6.5$  ( $P < 0.0001$ ) in patients in a mild depressive state and from  $51.9 \pm 3.6$  to  $47.8 \pm 6.9$  ( $P < 0.0001$ ) in those in a moderate/severe depressive state. On the other hand, the SDS score of patients in a non-depressive state increased significantly ( $32.2 \pm 4.5$  to  $34.1 \pm 7.5$ ,  $P = 0.0007$ ). In the sub-scales, the score of psychological equivalents decreased significantly in all patients ( $21.1 \pm 6.4$  to  $20.5 \pm 6.5$ ,  $P = 0.0003$ ). However, the score of pervasive effects and physiological equivalents did not change significantly in all patients. There was a significant increase in the score of physiological equivalents ( $14.6 \pm 2.7$  to  $15.1 \pm 2.8$ ,  $P = 0.0043$ ) and psychological equivalents ( $15.3 \pm 3.5$  to  $16.6 \pm 5.6$ ,  $P = 0.0098$ ) in patients in a non-depressive state. Nevertheless, the score of physiological equivalents and psychological equivalents decreased significantly in patients in a mild depressive state ( $17.4 \pm 2.8$  to  $16.8 \pm 2.9$ ,  $P = 0.0147$  and  $23.3 \pm 3.4$  to  $21.9 \pm 5.1$ ,  $P < 0.0001$ , respectively) and moderate/severe depressive state ( $20.1 \pm 3.0$  to  $19.0 \pm 3.6$ ,  $P = 0.0036$  and  $28.5 \pm 3.5$  to  $25.7 \pm 5.1$ ,  $P < 0.0001$ , respectively).

**Conclusion:** These results suggest that a diabetes education program may affect the physiological equivalents and psychological equivalents of the depressive score in type 2 diabetic patients.

## 974

**Poor adherence to therapy of depression in diabetes patients with insufficient metabolic control: results of the Diabetes Depression Study (DAD study)**

F. Petrak<sup>1</sup>, S. Herpertz<sup>1</sup>, C. Albus<sup>2</sup>, N. Hermanns<sup>3</sup>, K. Kronfeld<sup>4</sup>, B. Kulzer<sup>5</sup>, J. Kruse<sup>6</sup>, C. Ruckes<sup>4</sup>, M.J. Müller<sup>2</sup>;

<sup>1</sup>Clinic of Psychosomatic Medicine and Psychotherapy, LWL-University Clinic Bochum, <sup>2</sup>Klinik und Poliklinik für Psychosomatik und Psychotherapie, Universitätsklinikum, Köln, <sup>3</sup>Forschungsinstitut Diabetes-Akademie (FIDAM), Bad Mergentheim, <sup>4</sup>Interdisziplinäres Zentrum Klinische Studien (IZKS), Universitätsmedizin der Universität, Mainz, <sup>5</sup>Klinik für Psychosomatik und Psychotherapie, Universitätsklinikum, Gießen, <sup>6</sup>Vitos Klinikum, Marburg und Gießen-Marburg, Germany.

**Background and aims:** It is well established that depression impairs adherence to diabetes treatment. But, it is unclear if this is also the case for depres-

sion treatment. Therefore, we analysed adherence to therapy of depression in poorly controlled diabetes patients within a randomised controlled multicentre trial.

**Materials and methods:** Diabetes patients (type 1 or 2) with depression (Structured Clinical Interview for DSM-IV) were randomised to 50-200mg Sertraline (SER) or 10 sessions of a diabetes specific cognitive behavioural group therapy (CBT). Response regarding depression was assessed after 12 weeks (Hamilton Depression Rating Scale, HAMD: Baseline - 50% or  $\leq 7$ ). Adherence to treatment was defined by measuring the received therapy 'dose'; number of attended sessions were counted for the CBT group (0=nonadherent; 1-7=partially nonadherent; 8-10=adherent). For the SER group analyses of sertraline and N-desmethylsertraline in blood serum were performed after 8 and 12 weeks of treatment to measure adherence to treatment and serum target ranges were defined. Patients with SER concentrations twice within the target range were considered as adherent, once within the target range as partially nonadherent, and never within the target range as nonadherent. Group differences (adherent vs partially nonadherent or nonadherent) were analysed regarding patients characteristics and response to therapy using t-tests or Chi<sup>2</sup>-Tests.

**Results:** Within the CBT group (N=126) 54% (68/126) of patients were considered as adherent, 26.2% (33/126) as partially nonadherent and 19.8% (25/126) as nonadherent. For the SER group (N=120) 38.3% of patients were adherent (46/120), 28.3% (34/120) partially nonadherent, and 33.3% (40/120) nonadherent. Non-adherent patients were treated more often with insulin pumps (N=28 vs 13;  $p < 0.05$ ), they had a higher HbA<sub>1c</sub> ( $9.4 \pm 1.6$  vs.  $9.0 \pm 1.3$ ;  $p < 0.05$ ) and they suffered more often from very severe depression (HAMD $>25$ , N=16 vs. 3,  $p < 0.05$ ) compared to adherent patients. Significantly higher response rates were observed after 12 weeks of SER treatment for adherent patients compared to the partially adherent or nonadherent group ( $p < 0.05$ ), a difference that could not be observed within the CBT group.

**Conclusion:** A majority of patients did not adhere to their treatment. Only 54% of the CBT patients participated sufficiently in the therapy sessions and the vast majority of patients treated with sertraline did not take their medication as intended. Nonadherence predicted nonresponse for the sertraline treatment but not for the CBT.

**Temporal changes in the prevalence of depression and diabetes mellitus in a rural population of Bangladesh: from 2004 to 2009**

K. Natasha, B. Bhowmik, S. Asghar, A. Hussain;

Community Medicine, Institute of health and society, Faculty of Medicine, Oslo, Norway.

**Background and aim:** Unfortunately having least data on depression among rural diabetic people in Bangladesh we had been working in this field for last 2 decades. Referred to a previous study in that particular area, whether the situation is same or changed, we designed the study to freshly investigate the prevalence of depressive symptoms in individuals with and without diabetes in 2009.

**Method:** 952 and 2293 subjects aged  $\geq 20$  years in 2004 and 2009 respectively were collected from 10 villages of a rural community. Type 2 Diabetic cases (DM) were defined using the diagnostic criteria by World Health Organization. Simplified Montgomery and Asberg (MADRS) scale ( $\geq 20$  indicated depression) was followed for depression scoring. Risk indicators for depression in relation to socio-economic state, education, marital status and glucose abnormality, anthropometric measurements and gross clinical conditions were also assessed.

**Results:** Table: Selected socio demographical, economical and clinical data of the study population

	Healthy		DM only	Depression Only	Both			
	2004	2009	2004	2009	2004	2009	2004	2009
N (%)	648 (68.07%)	2038 (88.87%)	27 (2.84%)	148 (6.45%)	120 (12.61%)	74 (3.23%)	157 (16.49%)	33 (1.44%)
Age (Mean ±SD)	38.5 ± 12.3	41.42 ± 13.80	42.0 ± 9.0	45.01 ± 2.99	41.2 ± 14.8	45.59 ± 15.46	44.5 ± 8.8	43.09 ± 12.12
Male (%)	42.60	37.54	70.40	22.30	37.50	41.89	45.8	39.39
Female (%)	57.40	62.46	29.60	77.70	62.50	58.11	54.2	60.61
Monthly income (Taka) (Mean ±SD)	6658.00 ± 6648.00	7763.33 ± 5755.41	9463.00 ± 7367.00	8672.30 ± 6713.70	5917.00 ± 5747.00	8135.14 ± 5408.19	8685.00 ± 6194.00	10393.94 ± 6791.26
Physical activity (high)	72.40	73.99	81.5	65.54	74.20	62.16	68.8	66.67
BMI (Mean ±SD)	21.6 ± 4.0	22.46 ± 3.717	23.5 ± 3.2	24.77 ± 4.920	20.6 ± 3.2	21.76 ± 4.355	23.8 ± 3.8	25.60 ± 4.862
Systolic Blood Pressure (Mean ±SD)	117 ± 18	114.90 ± 16.075	123 ± 13	121.86 ± 17.036	119 ± 21	115.47 ± 20.139	123 ± 19	117.73 ± 17.098
WHR (Mean±SD)	0.88 ± 0.13	0.87 ± 0.06	0.93 ± 0.05	0.91 ± .06	0.86 ± 0.06	0.86 ± 0.07	0.93 ± 0.19	0.93 ± 0.06

\*\*1USD=68Tk(2004), 69Tk(2009)

Over all prevalence of Depression in 2004 and 2009 were 29% and 4.67% (95% CI) respectively though the mean age between the two studies were different (39 in 2004 and 41 in 2009). The depressive symptoms in subject with diabetes and without diabetes were 29.7% and 14.1% in 2004 and 18.2% and 2.3% in 2009.

**Discussion and conclusion:** The prevalence of depression in the later study was low specially in females, compared to the previous one, and more similar with the studies from National Institute of Mental Health, Bangladesh (4.6%), neighbour countries like Pakistan (5.8%) and India (7.4%). The systolic blood pressure declined also. The study supported the trend of diabetes which was upward (2.8% in 2004 and 6.45% in 2009). Improvements in the mean BMI score (according to WHO cut off point for Asian people) from 20.2±3.0 to 22.63 ± 3.9 and the mean financial status (USD 112.80 ± 83.62) was predicted to be the cause. It also could be predicted that less earning capacity and lack of socio technical facilities are the main cause of depression among people like ours. Our study area had expansions in their small (36.3%) and medium (46.2%) trade, electric supply (3.5%), sanitation (4.1%), health services and road and transport facilities within those 5 years the disease scenario changed. We can conclude with a stance that depression in rural developing area is based on low economic status. When the life standard increases the chance of NCD increases but depressive symptoms turn down.

### Validation of the Danish version of diabetes distress scale

L.E. Joensen<sup>1</sup>, I. Tapager<sup>2</sup>, I. Wilaing<sup>1</sup>

<sup>1</sup>Steno Health Promotion Center, Steno Diabetes Center, Gentofte, Denmark,

<sup>2</sup>Incentive Partners, Holte, Denmark.

**Background and aims:** Psychosocial problems are highly prevalent among diabetes patients. Different measures aim to assess the extent and the burden of psychosocial problems among persons with diabetes. The purpose of this study was to examine the internal consistency and validity of a Danish translation of the Diabetes Distress Scale (DDS) among adults with type 1 diabetes.

**Materials and methods:** Data was collected with a large cross-sectional survey of adults with Type 1 diabetes (N=2419, response rate 67%) in 2011. Validated scales and questions measured diabetes distress, diabetes empowerment (DES-SF), self-management behaviours, self-rated health (SF12) and quality of life (WHOQoL). An electronic patient record provided information about glycemic control (HbA1c). The Diabetes Distress Scale (DDS) consists of 17 items describing possible diabetes-related problems. The total score is derived as the sum of the 17 item scores divided by 17. The DDS is originally subdivided into four domains of diabetes related distress: emotional burden (EB), physician-related distress (PD), regimen-related distress

(RD) and diabetes-related interpersonal distress (ID). The original DDS was translated into Danish using an academic forward-backward translation procedure. Data was analyzed by computing Cronbach's alpha, factor analyses, t-test and pairwise Pearson correlations.

**Results:** Relatively few of the respondents (5.1%) left items in the scale unanswered. Overall, an acceptable number of respondents (6.3%) had the lowest possible score whereas none reached the maximum diabetes distress score. Exploratory factor analyses of DDS suggested that a 3 or 4 factor division into subscales was appropriate. If 4 factors were modeled, the division into factors corresponded almost precisely to the four domains described in the development of DDS. Only one item departed from the expected grouping and was highly correlated with the EB subscale as well as the RD subscale. The total scale had a Cronbach's  $\alpha$  of 0.92. The mean DDS-score was slightly higher for women than for men (2.0 vs. 1.8,  $p < 0.001$ ). Younger adults reported more diabetes related distress than older adults and adults with shorter diabetes duration reported more diabetes distress than adults with longer diabetes duration. Higher distress scores was correlated with low diabetes empowerment, low quality of life, unhealthy diet, not being physically active, poor glycemic control and low scores on the SF12 mental and physical component score. Analyses of HbA1c and DDS showed the highest correlation for regimen-related distress. The correlation with the SF12 physical component score was smaller than the correlation with the mental component.

**Conclusion:** Our results provide support for the use of this Danish adaptation of the 17 item Diabetes Distress Scale among adults with type 1 diabetes for screening for psychosocial distress. The scale has high internal consistency (Cronbach's  $\alpha$ 's) and the correlations with external measures confirm our hypotheses on the covariations of the underlying concepts. This supports the validity of the scale. The cross sectional nature of the study does not allow us to take into account possible day-to-day variation, test-retest reliability or sensitivity to changes over time. However, it is a testament to the reliability of the scale that the overall results of the analyses correspond well to previous investigations of the original version of the scale.

## 977

### Reliability and validity of the Chinese version of diabetes distress screening scale

M. Li, Y. Mo, L. Ji;

Peking University, Beijing, China.

**Background and aims:** Diabetes related distress is a common condition of patients with diabetes, which includes high levels of negative affect and associated with poor disease management. Diabetes Distress Screening Scale is a specific instrument that measures the diabetes related distress. The scale has been used widely in research and clinical practice. However, no published data are currently available on the instrument for the Chinese population. The aim of this study was to examine the psychometric properties of a Chinese version of the DDS scale (DDS-C).

**Materials and methods:** The reliability and validity of the DDS-C were evaluated in 202 outpatients with type 2 diabetes. Cronbach's  $\alpha$  coefficient, factor analysis, spearman's correlation and ROC curve facilitated the psychometric evaluation. The Self-rating Depression Scale (SDS) and Self-rating Anxiety Scale (SAS) scale were adopted to evaluate the criterion-related validity. One week test-retest reliability was measured.

**Results:** Exploratory factor analysis identified 4 sub-dimensions: emotional burden (EB), physician-related distress (PD), diabetes-related interpersonal and regimen distress (IRD), and medical resources-related distress (MRD). The last sub-dimension was different from the original scale which may reflect the cultural difference. The criterion-related validity of DDS-C between both SDS and SAS were acceptable ( $r_{\text{SDS}} = 0.625$ ,  $r_{\text{SAS}} = 0.633$ ,  $p < 0.01$ ). The internal consistency was good (Cronbach's  $\alpha = 0.892$ , Guttman split-half reliability = 0.895). The one week test-retest reliability was satisfactory ( $r_s = 0.9044$ ,  $p < 0.01$ ). The boundary value indicating depression emotion estimated by ROC curve was 47.5 with sensitivity of 0.656 and specificity of 0.85 while the boundary value indicating anxious emotion was 47.5 as well with sensitivity of 0.73 and specificity of 0.82.

**Conclusion:** This study suggested that the DDS-C has a consistent, generalizable factor structure with good internal reliability and validity, which could be used as a valuable instrument to assess diabetes-related distress in Chinese patients.

found between the diabetics on oral diabetic medication versus the insulin treated.

**Conclusion:** Diabetes in IHD seems specifically associated with increased depression score and lower physical quality of life. Splitting the diabetics into 2 groups of either high-high or low-low PPS and CSS seemed to gather all the different stress Q's, and the combination of the 2 might be usable for future research on the chronic stress burden in diabetes and IHD.

### Chronic stress as evaluated by pressure pain sensitivity and questionnaires in patients with ischaemic heart disease, with and without diabetes

N. Bergmann<sup>1</sup>, S. Ballegaard<sup>2</sup>, L. Andersen<sup>3</sup>, F. Gyntelberg<sup>4</sup>, C. Kistorp<sup>1</sup>, P. Holmager<sup>1</sup>, J. Faber<sup>1</sup>;

<sup>1</sup>Center of Endocrinology and Metabolism, Herlev University Hospital, Copenhagen, <sup>2</sup>Ull Care A/S, Hellerup, <sup>3</sup>Department of Cardiology P, Gentofte University Hospital, <sup>4</sup>The National Research Center for the Working Environment, Copenhagen, Denmark.

**Background and aims:** Diabetes and ischemic heart disease (IHD) are associated with chronic stress, which is a prognostic risk factor of mortality in IHD. Known questionnaires (Q's) of chronic stress covers typically only parts of the global stress concept. A newly developed hand-held device measures hyperalgesia, which seems to be stress-induced, on the sternum as Pressure Pain Sensitivity (PPS). PPS measurement is easy to perform, and might be used as a measure of chronic stress. The aim of the present study was to investigate chronic stress and the distribution of the different elements of the chronic stress-concept in diabetic patients with established and stable IHD, and to validate PPS and a newly developed 59 items stress score (CSS), both regarded as potential measures of the global concept of stress.

**Materials and methods:** A cross-sectional study of 361 patients with established and stable IHD of whom 47 (13%) had diabetes. Chronic stress was evaluated by PPS and by the following Q's: CSS, Quality of Life (SF-36), depression (MDI) and recent well-being (WHO-5). PPS was measured on the most sensitive point on sternum in the area of IC-4 to 5

**Results:** IHD patients with diabetes had a higher MDI score ( $r = 0.12$ ,  $p = 0.019$ ), lower SF-36 physical component summary score ( $r = -0.17$ ,  $p = 0.001$ ) and a lower score of several sub-measurements of the SF-36 as compared to non-diabetic IHD patients. No differences were found between diabetics and non-diabetics with regard to PPS or the other Q's. However, when comparing the most stressed diabetics, i.e. those with the highest tertiles of PPS and of CSS (high-high group) vs. those with the lowest tertiles of PPS and CSS (low-low group), the high-high group had increased MDI and reduced WHO-5 score and SF-36 mental component summary score ( $p = 0.048$ ,  $p = 0.047$  and  $p = 0.031$ , respectively). Compared to the non-diabetic IHD patients, the diabetics had higher angina score ( $r = 0.16$ ,  $p = 0.002$ ) but similar NYHA-score. CSS correlated to both angina- and NYHA score in both the diabetics and non-diabetics (all  $p < 0.001$ ) No differences in stress-measurements were

### Impact of bariatric surgery on life expectancy in adults with diabetes

P.J. O'Connor<sup>1</sup>, D. Schauer<sup>2</sup>, D. Arterburn<sup>3</sup>, E. Livingston<sup>4</sup>, K. Coleman<sup>5</sup>, S. Sidney<sup>6</sup>, D. Fischer<sup>7</sup>, M. Eckman<sup>8</sup>;

<sup>1</sup>HealthPartners Research Foundation, Minneapolis, <sup>2</sup>Division of General Internal Medicine, University of Cincinnati Medical Center, <sup>3</sup>Center for Health Studies, Group Health, Seattle, <sup>4</sup>Dept. of Gastrointestinal and Endocrine Surgery, University of Texas, Dallas, <sup>5</sup>Southern California Permanente Medical Group, Pasadena, <sup>6</sup>Kaiser Permanente Northern California, Oakland, <sup>7</sup>University of Cincinnati Medical Center, <sup>8</sup>Division of General Surgery, University of Cincinnati Medical Center, USA.

**Background and aims:** To determine the impact of gastric bypass on life expectancy for severely obese patients with diabetes.

**Materials and methods:** We developed a decision-analytic Markov model to evaluate two strategies for severely obese patients with diabetes: gastric bypass versus nonsurgical treatment. The efficacy of surgery was determined from a retrospective cohort of 165,000 severely obese diabetic patients (4500 had gastric bypass) from 4 HMO Research Network sites using fully adjusted Cox proportional hazards models. Logistic regression models calculated in-hospital mortality for surgery using data from the Nationwide Inpatient Sample (NIS). The decision model was calibrated using data from the National Health Interview Survey that is linked to the National Death Index. The model was constructed using Decision Maker<sup>®</sup>, which estimated changes in life expectancy.

**Results:** Our base case, a 40 year-old female with a BMI of 45, no hypertension, no coronary artery disease and no congestive heart failure, gained an additional 7.1 years of life expectancy with gastric bypass (43.1 years with surgery vs. 36.0 without). Surgery was no longer favored in our base case when 30-day surgical mortality exceeded 16% (baseline risk was 0.2%). Sensitivity analyses revealed that the gain in life expectancy decreases with increasing BMI, until a BMI of 62 is reached; at this point, nonsurgical treatment is associated with greater life expectancy than gastric bypass. Similar results for both men and women in all age groups were seen.

**Conclusion:** For most severely obese diabetic patients, gastric bypass surgery increases life expectancy; however, gastric bypass decreases life expectancy for those with a BMI over 62. Patients with high BMI may have other benefits from surgery, such as better quality of life and reduced burden of comorbid disease.

### Adherence to GLP-1 agonist therapy in US managed care

E. Chou<sup>1</sup>, M. Germe<sup>2</sup>, S. Schwartz<sup>3</sup>;

<sup>1</sup>R&D, Sanofi, Bridgewater, USA, <sup>2</sup>R&D, Sanofi, Paris, France, <sup>3</sup>Main Line Health System, Wynnewood, USA.

**Background and aims:** Non-adherence is a major obstacle for outcomes improvement in diabetes care. This study evaluated medication adherence with GLP-1 Agonist (GLP1) therapy.

**Materials and methods:** Patients who initiated a GLP-1 therapy during Apr 2005 to Dec 2010 with 1 year follow-up were identified from the Impact<sup>™</sup> Database. Adherence to GLP1 was approximated by medication possession ratio (MPR) as the ratio of days a patient had GLP1 drug in possession relative to the calendar days in the year after the drug initiation. Yearly adherence was defined as MPR ≥80%.

**Results:** Mean age of exenatide (EXEN: n=52,898) and liraglutide (LIRA: n=1,587) initiators was 53 years. Yearly adherence rate for EXEN decreased from 34% in 2005 to 20% in 2010, and was 31% in 2010 for LIRA. In A1C responders (<7%), adherence rate to both GLP-1 therapies was higher than in non-responders (OR=2.21; 1.98-2.46). The yearly rate of medical claims for nausea or vomiting was 4.5-5.2% for EXEN and 6.5% in 2010 for LIRA. Specifically for EXEN, nausea or vomiting were related with non-adherence in 2009 (Odds ratio [OR]=0.59; 95% CI: 0.40-0.85) and 2010 (OR=0.28, 0.13-0.59). EXEN adherence was associated with metformin use (OR=1.37; 1.27-1.48), endocrinologist care (OR=1.20; 1.14-1.26), or microvascular event (OR=1.20; 1.13-1.26) and hospitalization (OR=0.70; 0.64-0.76).

**Conclusion:** Adherence to EXEN or LIRA therapy is suboptimal and non-adherence to EXEN increased between 2005 and 2010. Adherence rate to

these GLP-1 therapies is lower in patients who do not achieve A1C goal than those who do. Medically treated nausea or vomiting and hospital admissions are contributing factors to non-adherence to EXEN therapy while endocrinologist care appears a mitigating factor. A new therapy with better tolerability may improve adherence hence patient outcomes.

### Real-world characteristics of patients with type 2 diabetes on basal insulin initiating add-on GLP-1 analogue therapy

M.R. Dalal<sup>1</sup>, Z. Ling<sup>1</sup>, K.L. Davis<sup>2</sup>, J.L. Meyers<sup>2</sup>, A. DiGenio<sup>1</sup>;

<sup>1</sup>sanofi-aventis U.S., Bridgewater, <sup>2</sup>RTI Health Solutions, Research Triangle Park, USA.

**Background and aims:** There is limited real-world data on patients treated with basal insulins plus glucagon-like peptide-1 (GLP-1) analogs. This study aimed to document the real-world patient characteristics and outcomes of type 2 diabetes mellitus (T2DM) patients treated with basal insulin with and without add-on GLP-1 analog therapy.

**Materials and methods:** Using the General Electric Centricity electronic medical records (EMR) database, a retrospective analysis was conducted in T2DM patients aged ≥ 18 years who initiated a basal insulin between January 2005 and January 2012. Patients had ≥ 6 months EMR activity prior to their index date and were stratified based on whether or not they initiated a GLP-1 analog as add-on therapy within the available follow-up period. Study index date was the first insulin prescription date for patients without subsequent add-on therapy (INS-only) and the first date of combined prescription of both drugs for patients with an add-on therapy (INS + GLP). INS-only patients were used as a reference group. Primary study endpoints included HbA<sub>1c</sub> levels and body weight and were analyzed descriptively during a maximum 12-month follow-up period. Hypoglycemia rates and gastrointestinal related events will be evaluated later.

**Results:** 29,684 patients were eligible (INS-only: N = 28743, INS + GLP: N = 939). Baseline demographic and clinical characteristics are shown (Table). At time of insulin initiation, HbA<sub>1c</sub> levels were similar for both groups. Mean HbA<sub>1c</sub> levels were 8.89% for INS-only patients at insulin initiation and 8.45% for INS + GLP patients at GLP add-on index date. Mean baseline body weight was 97.22 and 109.06 kg for INS-only and INS + GLP patients, respectively (Table). Median time between first insulin initiation date and GLP add-on date for INS + GLP patients was 468 days. At 6 months and 1 year post index date, INS-only patients showed a significant reduction in HbA<sub>1c</sub> levels from baseline of -0.77% (P < 0.0001) and -0.67% (P < 0.0001), respectively. Body weight in the INS-only group was significantly lower from baseline at 6 months (-0.24 kg, P < 0.0001), but not at 1 year after index date (+ 0.14 kg, P = 0.018, Table). INS + GLP patients also showed a significant reduction in HbA<sub>1c</sub> levels from baseline (6 months: -0.37%, P < 0.0001; 1 year: -0.35%, P < 0.0001). Body weight in the INS + GLP group was significantly lower from baseline at both time points (6 months: -1.90 kg, P < 0.0001; 1 year: -1.97 kg, P < 0.0001, Table).

**Conclusion:** This study demonstrates that in a real-world setting, the addition of GLP-1 analog therapy to basal insulin in T2DM patients can be associated with improved glycemic control and reduction in body weight. Further analyses are needed to investigate the impact of possible confounders on outcomes.

Table: Demographic and clinical characteristics of INS-only and INS + GLP patients

	INS-only (n = 28,743)	INS + GLP (n = 939)
Mean (sd) age, years	60.1 (12.8)	55.0 (11.2)
≥ 65 years, n (%)	11,171 (38.9)	195 (20.7)
Male, n (%)	14,215 (49.5)	430 (45.8)
Mean (sd) CCI score	1.1 (1.6)	0.8 (1.3)
Mean (sd) baseline HbA <sub>1c</sub> , %	9.04 (2.02)	8.93 (1.80)
Mean (sd) baseline weight, kg	97.22 (24.92)	109.06 (24.62)
Mean (sd) change in HbA <sub>1c</sub> , %		
6 months	−0.77 (2.00)*	−0.37 (1.39)*
1 year	−0.67 (2.06)*	−0.35 (1.58)*

## 982

### Is HbA<sub>1c</sub> a reliable measure for assessing glycaemic control?

M. Schweitzer<sup>1</sup>, D.A. Cavan<sup>2</sup>, R. Ziegler<sup>3</sup>, I. Cranston<sup>4</sup>, C. Parkin<sup>5</sup>, R.S. Wagner<sup>6</sup>;

<sup>1</sup>Roche Diagnostics GmbH, Mannheim, Germany, <sup>2</sup>Royal Bournemouth Hospital, Bournemouth, UK, <sup>3</sup>Diabetes Clinic for Children and Adolescents, Muenster, Germany, <sup>4</sup>Queen Alexandra Hospital, Portsmouth, UK, <sup>5</sup>CGParkin Communications, Inc., Boulder City, USA, <sup>6</sup>Roche Diagnostics, Inc., Indianapolis, USA.

**Background and aims:** HbA<sub>1c</sub> is generally considered the “gold standard” for assessing glycaemic control in people with diabetes. However, discrepancies between HbA<sub>1c</sub> values obtained from different methodologies have been reported. We assessed the correlation of results between immunoassay (IM) methodologies and high-performance liquid chromatography (HPLC).

**Materials and methods:** We compared paired baseline HbA<sub>1c</sub> values from two large clinical trials involving poorly controlled type 1 (T1DM) and type 2 (T2DM) diabetes. In our first comparison, blood samples for paired HbA<sub>1c</sub> values were obtained from 453 poorly controlled T2DM subjects, drawn from a large, cluster-randomized, multicenter study. HbA<sub>1c</sub> values were obtained from point of care (POC) tests, using IM methodology (A1C NOW+, Bayer Diagnostics, Tarrytown, New York, USA) and HPLC methodology (Variant II and Variant II Turbo haemoglobin testing systems, Bio-Rad Laboratories, Hercules, California, USA), performed at a central laboratory. Average HbA<sub>1c</sub> values were  $8.4 \pm 1.4\%$  and  $8.6 \pm 1.2\%$  for IM and HPLC, respectively. Our second comparison looked at paired baseline HbA<sub>1c</sub> values from 193 poorly controlled T1DM and T2DM subjects enrolled in the Automated Bolus Advisor Control and Usability Study (ABACUS), a large, prospective, randomized, multi-national study of poorly controlled ( $\text{HbA}_{1c} \geq 7.5\%$  /  $58 \text{ mmol/l}$ ) T1DM and T2DM, MDI-treated subjects. We compared baseline results obtained at local laboratories (using several methodologies) and central laboratory values (VII Turbo haemoglobin testing system, Bio-Rad Laboratories, Hercules, California, USA). Mean HbA<sub>1c</sub> values were  $9.04 \pm 1.17$  (local laboratory) and  $8.85 \pm 1.15\%$  (central laboratory).

**Results:** Analysis of the first data set revealed that IM results were lower than HPLC values. Although mean bias between methods was found to be acceptable at  $-0.18\%$ , standard deviation was  $0.96\%$ , and there was a significant difference ( $p < 0.001$ ) between method results as indicated by a 95% limit of agreement of  $-0.27\%$  to  $-0.09\%$  HbA<sub>1c</sub> (95% confidence interval [95% CI]),  $r = 0.74$ . IM values differed from HPLC laboratory values by  $>0.5\%$  HbA<sub>1c</sub> in  $>59\%$  of cases and by  $>1.0\%$  HbA<sub>1c</sub> in  $>27\%$  of the cases. In the second analysis, we saw a significant difference between the methodologies ( $p < 0.0001$ ) with a positive bias of  $0.15$  in IM methodology, and limits of agreement from  $0.09$  to  $0.21$  (95% CI),  $r = 0.92$ .

**Conclusion:** Because many clinicians still rely primarily on HbA<sub>1c</sub> test results when making treatment decisions, it is important that HbA<sub>1c</sub> values taken are accurate in order to avoid under-treating or over-treating patients. Given the discrepancies found in our analysis of two different data sets, cli-

nicians may consider use of self-monitoring of blood glucose (SMBG) in a structured manner, utilizing 7-point glucose profiles obtained over 3 consecutive days, to confirm actual levels of glycaemic control. These 7-point glucose profiles have been shown to highly correlate with HbA<sub>1c</sub> levels obtained from HPLC methodologies. Moreover, use of structured SMBG can provide important and unique clinical information about patterns of intra-day glycaemia variability that cannot be obtained from HbA<sub>1c</sub> testing, alone.

### Relative and absolute contributions of postprandial and fasting plasma glucose over a 24hour period

R. Peter<sup>1</sup>, G. Dunseath<sup>2</sup>, S. Luzio<sup>2</sup>, D. Owens<sup>2</sup>;

<sup>1</sup>Neath Port Talbot Hospital, UK, <sup>2</sup>Diabetes Research Group, Swansea University, UK.

**Background and aims:** To determine the relative and absolute contributions of postprandial glucose (PPG) and fasting/pre-prandial plasma glucose (FPG) over a 24 hour period and HbA<sub>1c</sub> respectively in persons with type 2 diabetes.

**Materials and methods:** Subjects ( $n = 52$ , 37 men) had 12 hour plasma glucose (PG) profiles determined in response to 3 serial, identical test meals, given at 0-240, 240-480 and 480-720, comprising the daytime period. The nighttime period was determined by extending the profile from the 720 minute value to the pre-breakfast value, corresponding to the 24 hour glucose level. The PPG exposure was calculated for each 4 hour meal period. Excess hyperglycaemia was calculated as the area above a PG concentration of  $5.5 \text{ mmol/L}$  for the whole 24 hour period. Fasting hyperglycaemia was the difference between the excess hyperglycaemia and the PPG exposure. Subjects were divided into 5 groups according to HbA<sub>1c</sub> (Gp1:  $<7\%$ , Gp2:  $7-7.5\%$ , Gp3:  $7.5-8\%$ , Gp4:  $8-9\%$ , Gp5:  $\geq 9\%$ ). The absolute contribution of PPG and fasting hyperglycaemia to excess HbA<sub>1c</sub> was also calculated.

**Results:** The relative contributions of PPG glucose exposure to 24hour excess hyperglycaemia for the 5 groups were 43.5, 34.2, 29.7, 23.5 and 17.8%, Gp 1-5 respectively ( $p = 0.004$ ) while the relative contributions of fasting hyperglycaemia increased from 56.5, 65.8, 70.3, 76.5 and 82.2%, from Gp1 to Gp5 respectively. Absolute contributions of PPG to excess HbA<sub>1c</sub> were not significantly different in the 5 groups, whilst the absolute contributions of fasting hyperglycaemia to excess HbA<sub>1c</sub> increased significantly as HbA<sub>1c</sub> increased.

**Conclusion:** The relative contributions of postprandial glucose to 24 hour excess hyperglycaemia still decreases as glycaemic control worsens, although fasting hyperglycaemia contributes substantially in all groups and increases as HbA<sub>1c</sub> deteriorates. However the absolute contribution of postprandial glucose to excess HbA<sub>1c</sub> does not differ significantly with varying glycaemic control over a 24 hour period.

## 984

**Rare, 'fast' haemoglobin variants may interfere with HbA<sub>1c</sub> measurement using ion exchange high performance liquid chromatography: implications for diagnosis of diabetes**S. Misra<sup>1</sup>, M.R. Hancock<sup>2</sup>, D. Roper<sup>2</sup>, B. Green<sup>3</sup>, R.A. Round<sup>4</sup>, R. Cramb<sup>4</sup>, S.E. Manley<sup>4</sup><sup>1</sup>Metabolic Medicine, Imperial Healthcare NHS Trust, London, <sup>2</sup>Clinical Biochemistry, Imperial NHS Trust, London, <sup>3</sup>Waters Corporation, Cheshire, <sup>4</sup>Clinical Biochemistry, University Hospital Birmingham Foundation NHS Trust, UK.

**Introduction:** Haemoglobin (Hb) variants are common and many are clinically silent. Ion exchange high performance liquid chromatography (IE HPLC) performed for HbA<sub>1c</sub> measurement often identifies variants, which, depending on their elution time can lead to over- or under-estimation of HbA<sub>1c</sub>. Most IE HPLC methods have been evaluated in the presence of common variants (e.g. Hb S & C). While most of the ~1500 variants detailed in the online Hb database are individually rare, they are cumulatively significant and a particular problem occurs if the variant or its glycated fraction co-elutes with HbA<sub>1c</sub>. Interference from undiagnosed Hb variants has a worrying impact when an absolute value of HbA<sub>1c</sub> is used to diagnose diabetes. We report 3 types of interference from Hb variants co-eluting with HbA<sub>1c</sub> on analyses performed using IE HPLC.

**Methods:** Cases presented to Clinical Biochemistry departments at our two hospitals. HbA<sub>1c</sub> was determined using Menarini-HA8160 or Tosoh G8 IE HPLC. Further analysis was performed using electrospray ionisation mass spectrophotometry (ESI-MS).

**Results:** Class 1: Distinct variant Hb's co-eluting with HbA<sub>1c</sub>. Variant Hb's were identified due to obviously abnormal chromatograms with 'error codes' generated by the analyser (figure 1). In each case the variant elutes with HbA<sub>1c</sub>. Hb Camperdown and K Woolwich have previously been shown to affect HbA<sub>1c</sub> analysis. However this is the first report of Hb J Iran interfering. These disproportionately large peaks can easily be identified. Class 2: Variants identified through asymmetry of the HbA<sub>1c</sub> peak. Asymmetry of HbA<sub>1c</sub> peaks was detected during analysis (figure 2). ESI-MS confirmed the presence of variants. Cases depict either a small peak eluting closely to HbA<sub>1c</sub> (Hb Belleville, Pyrgos and South Florida), or, a subtle shoulder to the normal HbA<sub>1c</sub> peak (Hb J-Bangkok, La Desirade and Riccarton). Analytical systems may not identify these anomalies, which if incorporated into the peak, can falsely increase HbA<sub>1c</sub>. Class 3: Undetectable variants, found by a discordant clinical picture. Figure 3 shows the chromatogram obtained from the blood of a 25-year-old lady exhibiting symptoms of tiredness. HbA<sub>1c</sub> was elevated at 152 mmol/mol (16.1%) (Menarini HA-8140), with a normal shaped peak. Fasting glucose performed was normal. ESI-MS revealed the patient was heterozygous for Hb Wayne, an alpha chain mutation. The true HbA<sub>1c</sub> was found to be 23mmol/mol (4.3%).

**Conclusion:** This case series highlights the heterogeneity with which fast Hb variants can interfere with HbA<sub>1c</sub> analysis. The classification system as outlined may help keep laboratory staff alert to potential interferences, which become critically important when using HbA<sub>1c</sub> for the diagnosis of diabetes. Though IE-HPLC is susceptible to interference, alternative methods (borate affinity chromatography / immunoassay) also have their limitations, which may not be easily recognisable. Requesting clinicians should be aware of the limitations of HbA<sub>1c</sub> analysis and query results discordant with the clinical picture. This is of even more importance when considering using HbA<sub>1c</sub> for the diagnosis of diabetes.

## 985

**Underutilisation of antihyperglycaemic combination therapy in eligible, treatment-naïve patients with type 2 diabetes mellitus**Y. Qiu<sup>1</sup>, A.Z. Fu<sup>2</sup>, M.J. Davies<sup>1</sup>, S.S. Engel<sup>1</sup><sup>1</sup>Merck Sharp & Dohme, Whitehouse Station, <sup>2</sup>Georgetown University Medical Center, Washington, USA.

**Background and aims:** Patients with type 2 diabetes mellitus (T2DM) are at increased risk for vascular morbidity and mortality. Glucose control with antihyperglycaemic agents has been shown to reduce the risk of microvascular and diabetes-related complications. The likelihood of reaching HbA<sub>1c</sub> treatment targets using monotherapy with antihyperglycaemic agents is low in T2DM patients with elevated HbA<sub>1c</sub> levels. Therefore, AACE/ACE guidelines recommend initiating dual oral combination therapy which includes metformin in untreated patients with an HbA<sub>1c</sub> of 7.6 to 9.0%. The purpose of

this analysis was to estimate the proportion of treatment-naïve patients with T2DM and an HbA<sub>1c</sub> of 7.6 to 9% who initiate antihyperglycaemic treatment with combination therapy and to determine patient-related factors associated with initiating combination therapy.

**Methods:** Using the US GE electronic medical records database, patients included in this analysis were those with a T2DM diagnosis from 2003 to 2010, at least one HbA<sub>1c</sub> measurement of 7.6 to 9% (first instance = index date), continuous enrollment in database for ≥12 months prior to and ≥6 months after index date, and no prescriptions for antihyperglycaemic agents in the 12 months prior to index date. Patients receiving prescriptions for any oral and/or injectable antihyperglycaemic agents as combination therapy (freely co-administered or fixed-dose included) or monotherapy within 30 days of index date were considered to have initiated therapy at index date. Logistic regression was performed to identify factors associated with initiating combination therapy.

**Results:** Of the 30,501 selected patients, 8% initiated antihyperglycaemic treatment with combination therapy and 36% initiated with monotherapy within 30 days of index date. Over the 2003 to 2010 time frame, the proportion of patients initiating any antihyperglycaemic monotherapy increased over time, but the proportion who initiated with combination therapy was relatively flat during this time period. After adjusting for baseline characteristics, patients with T2DM and an HbA<sub>1c</sub> of 7.6 to 9.0% were more likely to be prescribed combination antihyperglycaemic therapy if they had higher HbA<sub>1c</sub> (adjusted odds ratio [OR] = 1.78 [95% CI: 1.61, 1.97]). Patients were less likely to be prescribed combination antihyperglycaemic therapy if they were older (per 5-year OR = 0.95 [0.92, 0.97]), lived in regions outside of the Southern US (ORs ranged from 0.44 - 0.68 for different regions compared to South), or had chronic renal disease/renal failure (OR [95% CI] = 0.46 [0.28, 0.76]).

**Conclusion:** In a cohort of untreated patients meeting guideline recommendations for initiating combination antihyperglycaemic therapy, a low proportion of patients initiated with a broad range of combination therapies (8%) or any antihyperglycaemic regimen (44%). Greater efforts are needed to address underutilisation of antihyperglycaemic agents and the appropriate use of combination antihyperglycaemic therapy.

## 986

**Adding a 3rd agent to 2 oral antidiabetic drugs (OADs) - real-world economic impact and effect of treatment persistence on clinical outcomes**O. Baser<sup>1</sup>, S. Zhou<sup>2</sup>, W. Wei<sup>2</sup>, Z. Ling<sup>2</sup>, L. Xie<sup>1</sup>, P. Levin<sup>3</sup><sup>1</sup>STATinMED Research, Ann Arbor, <sup>2</sup>sanoofi-aventis U.S., Bridgewater,<sup>3</sup>MODEL Clinical Research, Baltimore, USA.

**Background and aims:** Patients with type 2 diabetes mellitus (T2DM) may need to intensify treatment when failing to maintain glycemic control with OADs only. This study assessed real-world clinical and economic outcomes, and the impact of treatment persistence, of adding a 3rd OAD (3OAD), a glucagon-like peptide 1 (GLP1) agonist (+GLP1), or insulin (+Insulin) to 2 OAD regimens.

**Materials and methods:** This retrospective cohort study used IMPACT<sup>®</sup>, a national managed care claim database, from 2000-2011. Included were adult T2DM patients previously on 2 OADs and initiating a 3rd OAD, GLP1, or insulin, with continuous health care coverage 6 months before (baseline) and 2 years after (follow-up) initiation. Within each cohort (3OAD, +GLP1, or +Insulin), we examined HbA<sub>1c</sub> and annual health care costs during baseline and the 1st and 2nd year of follow-up. We also assessed the association between HbA<sub>1c</sub> reduction from baseline and treatment persistence (ie, remaining on the initiated 3rd agent treatment class [OAD only, insulin, or GLP1] at the end of 1- or 2-year follow-up).

**Results:** A total of 51,771 patients (mean age 55.6 years, male 60.0%) were included (3OAD: 41052 [79.3%]; +Insulin: 6904 [13.3%]; +GLP1: 3815 [7.4%]). The 3 cohorts were significantly different at baseline, including HbA<sub>1c</sub> levels ( $P < 0.001$ ; Figure). During follow-up, annual drug costs increased in all 3 groups. However, +Insulin patients had decreased total costs (92% of baseline), mainly due to decreased inpatient costs (59% of baseline), while total and inpatient costs increased for 3OAD (139 and 155%) and +GLP1 (144 and 213%; Figure). At the end of 2-year follow-up, HbA<sub>1c</sub> reduction was -0.88% in +Insulin, -0.64% in 3OAD, -0.33% in +GLP1, among those with HbA<sub>1c</sub> data available (Figure). During follow-up, 2-year persistence rate was 72% in 3OAD, 57.1% in +Insulin, and 35.6% in +GLP1. In those with HbA<sub>1c</sub> data available, for +Insulin patients, 2-year treatment persistence was associated with greater HbA<sub>1c</sub> reduction, compared with switching during the 1st year (-0.99 vs

–0.59%,  $P = 0.032$ ); the opposite was observed for 3OAD (–0.65 vs –0.92%,  $P = 0.009$ ). No difference was observed in +GLP1 (–0.48 vs –0.23%,  $P = 0.128$ ). **Conclusion:** This real-world study showed that most T2DM patients added a 3rd OAD, instead of insulin or GLP1 after failing 2 OADs. All patients had HbA<sub>1c</sub> reduction during 2-year follow-up, but only the +Insulin group had decreased HbA<sub>1c</sub> and decreased total health care costs. Both 3OAD and +GLP1 groups had significant increase in health care costs, due to increased inpatient and drug costs. Treatment persistence was associated with better HbA<sub>1c</sub> reduction in the +Insulin group; the opposite was observed in the 3OAD group. This data supports the call for timely intensification and persistent use of insulin among T2DM patients not maintaining glycemic control with multiple OADs.

Graph: Health care costs (left Y-axis, bars) and HbA<sub>1c</sub> levels (right Y-axis, diamonds) at baseline, 1-year follow-up, and 2-year follow up, for patients from the total cohort adding a 3rd oral, insulin, or GLP1 to 2 OADs.

## 987

### The role of work related factors to glycaemic control in employees with diabetes

A.M. Mansinho<sup>1</sup>, C.L. Oliveira<sup>1</sup>, C.P. Paulo<sup>1</sup>, G.D. Alexandre<sup>1</sup>, I.M. Pereira<sup>1</sup>, J.F. Azevedo<sup>1</sup>, M. Almeida<sup>1</sup>, J.F. Raposo<sup>1,2</sup>

<sup>1</sup>Public Health Department, New University of Lisbon, <sup>2</sup>Diabetes Portugal, Lisbon, Portugal.

**Background and aims:** The work environment seems to influence the level of adaptation of employees with diabetes. Nevertheless little research exists. A bad disease adaptation can cause a greater absenteeism among people with diabetes. Our aim is to describe which work factors could influence the glycaemic control and evaluate the impact of Diabetes on the work ability.

**Materials and methods:** Descriptive cross-sectional and observational study. The clinical data was collected by a self-completed survey instrument. The work-related factors were collected using the Job Stress Scale (JSS) with 3 dimensions (demand, control and social support). Participants and settings: People with type 1 or type 2 diabetes employees (n=101) aged 18 to 67 years attending a portuguese diabetes center during 2 weeks of March.

**Results:** The mean age was 45.8 (±12.5) years (DM1 39.6; DM2 52.4), 70.3% were male; 67.3% had less than 12 years of education, the average duration of diabetes was 13.3 (±8.4) years. Fifty-two (51.5%) had DM1 and 49 (48.5%) DM2. The duration of diabetes was longer in DM1 (16.7±12.5y) than in DM2 (9.7±5.1y) ( $p=0.00$ ). Concerning JSS, higher level of demand score (14.8) control (18.7) and social support (20.6) suggested better metabolic control HbA<sub>1c</sub> (8.0%). Sixteen percent (n=16) indicated professional dissatisfaction of which 87.5% had a worse metabolic control. To note that 16% of diabetics did not inform their supervisors that they had diabetes. Thirty patients (29.7%) modified some of their work tasks and 26 (25.7%) interrupted some of them. People with type 1 diabetes evidenced an average absenteeism of 5.3 days, in the last 3 months, versus a 1.9 average for type 2 diabetes. Patients with complications associated to the disease missed their work, an average of 7.2 days against 1.3 of the ones with no complications.

**Conclusion:** The results suggest that people with diabetes, higher education, increase demand, control and social support at work could have better metabolic control. Some work factors such as satisfaction seem to interfere with glycaemic control. Diabetes is a chronic disease whose physical and psychological adaptation to the work environment is a key factor to retrieve them

to the labour market. Future work should corroborate some of these findings. On the other hand it will be important to develop worksite interventions to facilitate the proper and adequate integration of people with diabetes in their workplace to reduce absenteeism.

## 988

### The association between income and long term glycaemic control

S.D.M. Bot<sup>1</sup>, L. Kingo<sup>2</sup>, E. van 't Riet<sup>2</sup>, J.M. Dekker<sup>2</sup>, G. Nijpels<sup>1</sup>

<sup>1</sup>Department of General Practice, <sup>2</sup>Department of Epidemiology and Biostatistics, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

**Background and aims:** It is well known that low socio economic status (SES) is associated with adverse diabetes outcomes. Most studies examining the association between SES and diabetes outcomes have used a cross-sectional design. In this study we present longitudinal data on the association between income, as indicator of SES, and long term changes in HbA<sub>1c</sub> using patient data of a structured diabetes care system in the Netherlands.

**Materials and methods:** Patients with type 2 diabetes who entered a diabetes care system in the Netherlands between 1998 and 2010 were followed annually for up to 12 years. SES was based on census data on average household income using patient postal code data, and median income tertiles were derived. Baseline differences across the three income groups were compared using  $\chi^2$  analysis for dichotomous variables and linear regression for continuous variables. Linear mixed model analyses were performed to compare differences in mean HbA<sub>1c</sub> between income groups during follow-up using SPSS 17.

**Results:** Income data were available of 7571 patients of a total of 8245 patients who entered the diabetes care system during the study period. At entry, demographic and clinical characteristics differed significantly across income groups with higher age (mean 66 years ± 12.6 vs mean 60 years ± 11.3;  $p<0.001$ ), more women (59% vs 42%;  $p<0.001$ ), and longer duration of diabetes (mean 4.0 ± 6.6 vs 2.8 ± 5.2;  $p<0.001$ ) in the lowest income group compared to the highest income group. In Figure 1, the course of HbA<sub>1c</sub> for the three income groups is shown. Mean difference in HbA<sub>1c</sub> over 12 years, adjusted for age and sex, was 0.20 (95% CI, 0.14 to 0.26) between the highest and lowest income group. This difference attenuated to 0.14 (95% CI, 0.08 to 0.20) when additionally adjusted for diabetes duration and year of entry.

**Conclusion:** Diabetes patients with a lower income are diagnosed at a higher age. Despite equal access to care for all patients, income had a significant impact on long term glycaemic control in this large-scale population of type 2 diabetes patients.

Figure 1. Mean HbA<sub>1c</sub> per income group during up to 12 years follow-up (low: median monthly income of 1300 euro; moderate: 1700 euro; high: 2200 euro)

## PS 082 Diabetes education

989

### A new web site hosting serious games to promote education for flexible insulin therapy, insulin pump and continuous glucose monitoring

M. Joubert, A. Guillaume, Y. Reznik;

Endocrinology Unit, University Hospital of Caen, France.

**Background and aims:** The intensified insulin therapy with multiple daily injections (MDI) or continuous subcutaneous insulin injection (CSII) is the gold standard for treatment of type 1 diabetes. In addition, education to flexible insulin therapy (FIT) can improve dietary freedom and quality of life while maintaining good glycemic control. In recent years, personal continuous glucose monitoring (CGM) has emerged as an additional technology to improve type 1 diabetes control. These technological devices (CSII and CGM) and the FIT method need to be implemented with patients as part of therapeutic education programs that are time consuming for caregivers. This last point represents a limitation for the spreading of these therapeutic modalities. To address this problem, we developed serious games to be used as educational tools for CSII, CGM and FIT.

**Materials and methods:** These serious games have been developed by a multi professional team including diabetes physicians, therapeutic education physicians, nutritionists, diabetes nurses, game designers and computer scientists. These interactive media are hosted on a website in French and English language in free access. There are 3 games dedicated to children, adolescents and young adults.

**Results:** The two major serious games are “Birman Case” and “Time-Out”. These are adventure games starring a hero with type 1 diabetes using the FIT method in MDI or CSII (with or without CGM option). The player have to help the main character to manage his diabetes during the game. These games are enhanced with a glycemic variation simulator that makes them realistic and truly interactive. The simulator of “Time-Out” is based on a validated metabolic model and operates in accelerated real-time. Several situations that can induce hypo- or hyperglycemic state are imposed to the player during the game: meals containing various amount of carbohydrates, unplanned physical activity, alcohol absorption, pump failures... The player will have to manage these situations using insulin boluses, basal rate adaptation, carbohydrate intake... A summary of the therapeutic behavior of the player appears at the end of each game and can be exported to the physician. This report might be used as an evaluation and educational support. A multicentric french clinical study has begun to evaluate the impact of these games on type 1 diabetes patients knowledge and behaviour.

**Conclusion:** These educational tools are not a substitute for an education program offered by a team of health professionals but they can be integrated in such programs for the initiation, initial education, strengthening or evaluation.

990

### My diabetes my way: empowering people with diabetes through electronic record access

S.G. Cunningham<sup>1</sup>, R.R. McAlpine<sup>1</sup>, M. Brillante<sup>1</sup>, L. Wilson<sup>1</sup>, A. Waller<sup>2</sup>,

A. Emslie-Smith<sup>3</sup>, J. Walker<sup>4</sup>, A. Morris<sup>5</sup>, D. Wake<sup>5</sup>;

<sup>1</sup>Clinical Technology Centre, University of Dundee, <sup>2</sup>School of Computing, University of Dundee, <sup>3</sup>Diabetes Support Centre, Ninewells Hospital, Tayside Diabetes Managed Clinical Network, Dundee, <sup>4</sup>St John's Hospital, NHS Lothian, Livingston, <sup>5</sup>Clinical Research Centre, University of Dundee, UK.

**Background and aims:** My Diabetes My Way (MDMW - [www.mydiabetes-myway.scot.nhs.uk](http://www.mydiabetes-myway.scot.nhs.uk)) is the official NHS Scotland information portal, containing validated educational materials for people with diabetes and their carers. In December 2010 a new service was launched, allowing patients from across the whole of Scotland access to their shared electronic medical record. The source data is collected by the national diabetes system, Scottish Care Information - Diabetes Collaboration (SCI-DC). We aimed to analyse the first year of usage and uptake.

**Materials and methods:** A system was developed, containing information collected from primary care, secondary care, specialist screening services and laboratory systems across Scotland. It includes key diagnostic information; demographics; laboratory, lifestyle, foot and eye screening results; prescribed medication and clinical correspondence. This information was made available from the NHS Scotland 'shared diabetes record'. Changes can be tracked

over time using 'history' graphs and tables. Data items link to detailed descriptions, explaining why they are collected, what they are used for and what 'normal' values are. Tailored information links refer individuals to further facts related to their condition.

**Results:** 224 people with diabetes across all Scotland's 14 health boards have now accessed their own information. During the first year, 160 users accessed the system (most logins=164), with 1425 logins in total (average=8.9/patient; median=4). Audit trails show 19497 page views (122/patient), with laboratory 'test results' proving the most popular (3219 accesses;20/patient). The most utilised history graph was, unsurprisingly, HbA1c (793 accesses;5/patient). Feedback: “The knowledge provided helps me understand the normal parameters and where I stand/can improve”.

**Conclusion:** Although there are other patient access systems available worldwide, the MDMW system is unique as it provides access to information collected from all diabetes-related data sources. The system supports the self-management agenda of the Scottish Government and the objectives of the NHS Scotland Healthcare Quality Strategy. It is person-centred as it involves the individual in their care by allowing them to become partners in their clinical data monitoring. It is “timely” by providing rapid access to contemporary clinical results and is “equitable” by being available to all.

*Supported by: Scottish Diabetes Group*

991

### Who is using Twitter to communicate about diabetes and what for?

G. Gimenez-Perez<sup>1</sup>, M. Robert-Vila<sup>2</sup>, A. Recasens<sup>1</sup>, O. Simó<sup>1</sup>, I. Castells<sup>1</sup>;

<sup>1</sup>Diabetes, Endocrinology and Nutrition Unit, Hospital General de Granollers, Barcelona, <sup>2</sup>Institut Catala de la Salut; ABS Moli Nou, Sant Boi de Llobregat, Spain.

**Background and aims:** Web 2.0 tools have rapidly changed the way people communicate, and can potentially change health provider-patient interactions. Twitter is a widely used web 2.0 microblogging system using messages of less than 140 characters, which can be read by all twitter users. Positioning a hashtag (#) before the relevant words is used by tweet publishers to highlight tweet subject and facilitate its finding. The aim of this study was to analyze tweets and Twitter publishers related to diabetes in order to explore its potential as a communication tool between diabetes health providers and patients.

**Materials and methods:** All tweets under #diabetes published during periods of 1 hour (coordinated universal time (UTC) 1, 6, 11, 16 and 21 hours) of two working days were selected and stored under the favorites section of an on purpose Twitter address (@web20diabstudy) until further analysis. Tweet's origin, content and links were assessed by 2 investigators. Differences were solved by agreement. We also selected, using a list of random numbers, 100 out of the first 500 twitter addresses which displayed the word “diabetes” or “diabetic” in their description and evaluated the type of publisher behind the address.

**Results:** A total of 446 tweets were retrieved. 342 (77%) were English written and were further analyzed. 145 (42%) came from personal addresses (44% patients or relatives; 16% professionals; 40% others). 138 (40%) were from corporate addresses (64% private companies; 23% non-profit organizations; 13% healthcare organizations). The remaining (59; 18%) were from news and medical websites or others. On a whole 42 (12%) came from a health care provider (organization or professional). 260 (76%) of tweets offered a link to an additional source, mainly webpages or blogs (57%). Tweet's subjects were quite uniformly distributed with 73 (12%) tweets about treatment, 57 (16%) about personal experiences and 51 (15%) about diet. 53% of tweets published by patients or relatives related to personal experiences. In 167 (49%) tweets an intention of branding or selling was evident either in the tweet itself or in the publisher's address. Non-profit organizations and patients accounted for 56% (28% each) of the Twitter addresses evaluated, with only 4% belonging to healthcare professionals or organizations.

**Conclusion:** Twitter is a useful tool to identify patients with diabetes and therefore to explore their personal experiences and thoughts. Although Twitter might allow the communication between diabetes healthcare providers and patients with diabetes, at present healthcare providers are underrepresented in the Twitter world. Branding yourself or indirectly selling products is one of the main activities seen under #diabetes.

## 992

**The effect of a self-management oriented education and treatment programme (PRIMAS) for type 1 diabetic patients**

**B. Kulzer**, N. Hermanns, D. Ehrmann, N. Bergis, T. Haak;  
Research Institute of Diabetes Academy Mergentheim (FIDAM), Bad  
Mergentheim, Germany.

**Background and aims:** In a randomised, multi-centre trial, the effect of a structured education and treatment programme to promote self-management and empowerment for type 1 diabetic patients (PRIMAS) was compared to an established education programme (Structured education and treatment programme for type 1 diabetic patients) as an active comparator condition (ACC). Besides optimizing insulin treatment by testing basal insulin doses and carbohydrate factors as well as avoiding acute and late complications the PRIMAS programme also aims at motivational factors and the daily routine of living with diabetes.

**Materials and methods:** A total of 160 patients with type 1 diabetes recruited in diabetologist practices (PRIMAS: age  $45.9 \pm 13.8$  yrs, diabetes duration  $19.6 \pm 12.8$  yrs., 38.3% female, HbA1c  $8.3 \pm 1.1\%$ , 23.5% with CSII vs. ACC: age  $45.2 \pm 13.4$  yrs, diabetes duration  $19.4 \pm 13.2$  yrs., 49.4% female, HbA1c  $8.1 \pm 0.9\%$ , 27.8% with CSII) were randomised to either PRIMAS or the ACC. Main outcome was the HbA1c 6 months after participation in the respective programme. Secondary outcomes were diabetes related distress (Diabetes Distress Scale 17 items), extent of self-perceived empowerment (Empowerment scale 11 items), self-efficacy for diabetes management (Self-efficacy scale 10 items), diabetes knowledge (Knowledge test 11 items), and self-care behaviour (Summary of Diabetes Self Care Activity Scale). Baseline adjusted results are reported as mean  $\pm$  SEM.

**Results:** Baseline adjusted HbA1c was significantly more improved in PRIMAS than in the ACC ( $-0.33 \pm 0.1\%$  vs.  $-0.03 \pm 0.1\%$ ,  $p=.028$ ) at 6 month follow-up. Also patients treated with PRIMAS reported lower baseline adjusted diabetes related distress levels (mean item score  $0.9 \pm 0.1$  vs.  $1.1 \pm 0.1$ ,  $p=.049$ ), higher empowerment ( $27.4 \pm 0.5$  vs.  $26.0 \pm 0.5$   $p=.027$ ) and self-efficacy levels (mean score:  $23.3 \pm 0.4$  vs.  $21.9 \pm 0.4$   $p=.044$ ) than patients in the ACC. Satisfaction with insulin treatment was also higher after 6 month in PRIMAS than in the ACC (mean score:  $27.1 \pm 0.6$  vs.  $25.3 \pm 0.6$ ;  $p=.028$ ). Effects on knowledge (mean score  $7.7 \pm 0.2$  vs.  $7.9 \pm 0.2$   $p=.555$ ) and self-care behaviours (mean score:  $3.7 \pm 0.1$  vs.  $3.8 \pm 0.1$ ;  $p=.846$ ) did not differ significantly between the education programmes nor did insulin dose ( $0.66 \pm 0.02$  vs.  $0.63 \pm 0.02$  IU/kg;  $p=.284$ ).

**Conclusion:** PRIMAS is more effective in lowering HbA1c than the established education programme in type 1 diabetic patients. In addition, PRIMAS has proven its efficacy regarding the improvement of empowerment, self-efficacy and satisfaction with insulin treatment as well as regarding the reduction of diabetes related distress. The effects on knowledge and self-care behaviour are similar to those of the established education programme. Thus, PRIMAS provides a good alternative for treatment and education of type 1 diabetic patients.

## 993

**Impact on diabetes behaviours: knowing versus guessing blood glucose values**

**S.V. Edelman**<sup>1,2</sup>, J. Pettus<sup>1</sup>, J. Greer<sup>2</sup>, P. Stenger<sup>3</sup>, H.C. Schachner<sup>3</sup>, N. Dunne<sup>3</sup>, J.L. Parkes<sup>3</sup>, S. Pardo<sup>3</sup>;

<sup>1</sup>Division of Endocrinology, Diabetes and Metabolism, University of California at San Diego, <sup>2</sup>Taking Control Of Your Diabetes, Del Mar, <sup>3</sup>Bayer HealthCare LLC, Diabetes Care, Tarrytown, USA.

**Background and aims:** Research suggests that some people with diabetes use perceptions of their blood glucose (BG) levels rather than BG testing to make decisions about their diabetes management. This study was conducted to assess the difference between self-reported, estimated BG values and BG values as measured on a BG meter. Another objective of the study was to obtain information on the perceptions that people with diabetes have about BG testing and the impact of knowing their BG value on their diabetes management.

**Materials and methods:** Subjects aged  $\geq 18$  years with type 2 diabetes (N = 297) attending 1 of 2 Taking Control of Your Diabetes (TCOYD; 501c3) conferences were asked to take a pre-fingerstick questionnaire about their diabetes management. Subjects were then asked, "What do you think your blood sugar level is now?" Study staff then performed a fingerstick to measure

the subject's BG value on a BG meter. Subjects were advised of their BG value and were asked to respond to additional statements related to their BG testing practices on a post-fingerstick questionnaire.

**Results:** On the pre-fingerstick questionnaire, the majority of subjects either strongly agreed, agreed, or neither agreed/disagreed with the statement, "My body tells me without testing if my blood sugar is low or high" (77%) and made decisions about their diabetes, such as insulin dosing, without testing on a BG meter (71%; Table 1). However, nearly half (46%) of subjects estimated BG values that were outside current ISO accuracy guidelines (ie, more than  $\pm 15$  mg/dL or  $\pm 20\%$  of meter glucose values  $<75$  and  $\geq 75$  mg/dL, respectively); 58% estimated BG values that were outside proposed more stringent accuracy guidelines (ie, more than  $\pm 15$  mg/dL or  $\pm 15\%$  of meter glucose values  $<100$  and  $\geq 100$  mg/dL, respectively). On the post-fingerstick questionnaire, nearly all subjects reported that knowing their blood sugar level by checking could help them make different diabetes decisions (99%), give them more confidence in their ability to manage their diabetes (98%), help them prevent low BG (98%), help them recognize and treat low BG (98%), and give them a better understanding of how food affects their BG level (98%; Table 1). In addition, 99% of subjects responded that they would make different decisions about their meals/snacks if they knew their BG by checking on a BG meter. Among subjects taking insulin (n = 86), 98% felt that checking their BG on a meter could give them more confidence in adjusting their daily insulin dose.

**Conclusion:** These findings suggest that regular self-monitoring of BG versus guessing can contribute a significant impact on diabetes management behaviors in people with diabetes.

**Table 1. Subject Questionnaire Results**

Table 1. Subject Questionnaire Results							
Statement	Number of subject responses (N = 294)						N, A, or SA*
	SA	A	N	D	SD	N/A	
<b>Pre-fingerstick questionnaire</b>							
My body tells me without testing if my blood sugar is low or high	83	127	34	49	19	2	77%
I make decisions about my diabetes, such as my food intake or my insulin dose even when I do not test my blood sugar	43	154	11	58	25	3	71%
<b>Post-fingerstick questionnaire</b>							
<b>Knowing my blood sugar by checking</b>							
Could help me make different diabetes decisions	172	113	5	3	1	0	99%
Could give me more confidence in my ability to manage my diabetes	176	107	6	4	1	0	98%
Could help me prevent low blood sugar	162	112	18	2	3	7	98%
Could help me recognize and treat low blood sugar	176	107	6	4	1	0	98%
After I eat could give me a better understanding of how food affects my blood sugar levels	162	112	18	2	3	7	98%
Gives me more confidence in adjusting my daily insulin dose	48	29	7	1	1	205	98%
<b>I would make different decisions in my meals/snacks if I knew my blood sugar by checking</b>	164	115	6	2	1	6	99%

SA, strongly agree; A, agree; N, neutral; D, disagree; SD, strongly disagree; N/A, not applicable.

\*Responses of N/A were not included in the total responses for the purposes of the percentage calculation.

**A meta-analysis of pedometer-based care on physical activity and health outcomes in type 2 diabetes mellitus**

**S. Qiu**, X. Cai, B. Yang, Z. Sun, J. He;

Department of Endocrinology, Zhongda Hospital, Institute of Diabetes, Medical School, Southeast University, Nanjing, China.

**Background and aims:** Pedometers have recently been widely used as a tool for motivating and monitoring physical activity (PA) in type 2 diabetes (T2DM). However, the concrete effects of pedometer-based care on diabetes education and management are unknown. Therefore, we aimed to conduct a meta-analysis of randomised controlled trials (RCTs) in order to evaluate the effectiveness of pedometer-based care on PA and health outcomes in T2DM.

**Materials and methods:** Search strategy MEDLINE, EMBASE and Cochrane Library from 1994 to 29 February 2012 were searched. And the related references of all articles collected were checked to make sure that no relevant suitable studies were missed. Selection criteria All RCTs in English-language were included if they made evaluations of pedometer-based care intervention using pedometer as a motivational tool to increase PA in T2DM with a reported change in steps per day assessed by pedometers. Data collection and analysis Two investigators independently selected trials, assessed trial quality and extracted data. Continuous data were calculated as mean differences (MD). Random-effects model and fixed-effects model were used to perform meta-analysis for with and without heterogeneity respectively.

**Results:** Only six articles containing 10 RCTs were available for pooling involving 597 participants. Compared with the control group, the daily step count in the pedometer-based care intervention group was significantly increased by 1782 over baseline (95% confidence interval (CI) 643 to 2920;  $P<0.0001$ ), and the body mass index (BMI) was decreased by 2.46 (95% CI, -3.55 to -1.37;  $P<0.0001$ ). However, there were no statistically significant improvements in glycated haemoglobin (HbA<sub>1c</sub>) (-0.19%, 95% CI -0.41% to 0.03%;  $P=0.09$ ), total cholesterol (TC) (-0.17 mmol/L, 95% CI -0.34 mmol/L to 0.00 mmol/L;  $P=0.06$ ) or diastolic blood pressure (-1.21 mmHg, 95% CI -2.79 mmHg to 0.37 mmHg;  $P=0.13$ ).

**Conclusion:** Although our overall results suggest that pedometer-based care has an association with significant increases in PA and significant decreases in BMI, we find no statistically significant improvements in HbA<sub>1c</sub>, TC or diastolic blood pressure and additional RCTs are needed on these topics.

## 995

### The 'piecing together diabetes' education tool improves healthcare professional knowledge and inpatient diabetes care

R. Herring<sup>1</sup>, C. Pengilly<sup>1</sup>, H. Hopkins<sup>1</sup>, B. Tuthill<sup>1</sup>, N. Patel<sup>2</sup>, C. Nelson<sup>3</sup>, A. Currie<sup>4</sup>, D. Russell-Jones<sup>1</sup>

<sup>1</sup>Centre for Endocrinology, Diabetes and Research, Royal Surrey County Hospital, Guildford, <sup>2</sup>St Georges Hospital, London, <sup>3</sup>Northern General Hospital, Sheffield, <sup>4</sup>Hillingdon Hospital, Middlesex, UK.

**Background and aims:** Twenty percent of the United Kingdom's inpatient population have diabetes. In 2009, the National Diabetes Inpatient Audit identified that healthcare professionals often lack the confidence and knowledge to manage this patient group appropriately. We developed a novel inter-professional diabetes educational tool for use in the hospital environment. The jigsaw design incorporates all aspects of inpatient care from admission to discharge. Diabetes specialists facilitate learning through a combination of discussions, skills and activities.

**Materials and methods:** The education tool was piloted in four public hospitals in the United Kingdom. Thirty-one healthcare professionals were educated: 3 pharmacists, 17 nurses, 8 healthcare assistants and 3 junior doctors. The educational intervention was evaluated using Kirkpatrick's model, which assessed the learner's reaction, learning and behaviour and clinical outcomes related to key areas of inpatient diabetes care.

**Results:** Healthcare professional's confidence improved from 58% to 94% ( $p=0.002$ ) and knowledge improved from  $12.4\pm0.6$  to  $15.0\pm0.6$  (mean  $\pm$  SEM,  $p=0.005$ ). Appropriate blood glucose monitoring improved from 67% to 92% ( $p=0.026$ ). Management errors were reduced from 74% to 44% ( $p=0.045$ ) with appropriate hypoglycaemia management improving from 9% to 75% ( $p=0.003$ ). The number of patients with documented foot assessment improved from 15% to 33% ( $p=0.036$ ). Improvement in the number of appropriate diabetes referrals and reduction in prescribing errors did not reach statistical significance.

**Conclusion:** The well designed inpatient-teaching tool can be delivered effectively to healthcare professionals. The adaptability of the modules both in time and content made it user friendly. Widespread application of this tool could provide hospital staff with a robust, flexible and validated education tool, improve patient safety and potentially reduce inpatient care costs.

## 996

### Adherence to diabetes guidelines is a matter of behaviour of physicians rather than their knowledge levels

C. Yilmaz<sup>1</sup>, I. Satman<sup>2</sup>, S. Imamoglu<sup>3</sup>, on behalf of ADMIRE Study Group; <sup>1</sup>Internal Medicine, Endocrinology & Metabolism, Ege University Faculty of Medicine, Izmir, <sup>2</sup>Internal Medicine, Endocrinology & Metabolism, Istanbul University, Istanbul Faculty of Medicine, <sup>3</sup>Internal Medicine, Endocrinology & Metabolism, Uludag University Faculty of Medicine, Bursa, Turkey.

**Background and aims:** Clinical practice guidelines on diabetes mellitus (DM) have been revised in 2009 by The Society of Endocrinology & Metabolism, Turkey. The ADMIRE Project is designed to evaluate the effect of implementation activities to increase physicians' awareness on guidelines. The aim of this abstract is to determine relationship between the knowledge level about the recommendations in guidelines and the level of adherence of physicians to guidelines during follow-up of diabetes patients in Turkey.

**Materials and methods:** The study had two phases: "retrospective" and "prospective." Here we evaluated the prospective phase. In the initial period, medical records of 885 T2DM patients of 175 physicians were kept for 6 months, previous to awareness activities (PRE). Then, following a series of activities with the intention to increase the awareness of physicians on DM guidelines (POST), medical records of another group of 1,616 T2DM patients were kept for 6 months. In POST, physicians were asked to complete a 20 items questionnaire to measure their knowledge level (scored over 100). Adherence to guidelines was evaluated for two facets of patient management: (1) adherence to follow-up procedures (ADH\_FU), with three subdomains for medical history (HIST), physical examination (PE) and laboratory evaluation (LAB) (2) and adherence to treatment decisions with regards to management of patients with antidiabetic, antihypertensive and antilipid medications. The adherence scores between PRE and POST were compared, and the correlation coefficients between knowledge score and adherence scores were calculated.

**Results:** Physicians' average total score of knowledge on guidelines were 54.6. Their mean adherence scores, over 10, in PRE and POST were as follows: HIST 8.17 vs. 8.90 ( $p=0.022$ ), PE 4.79 vs. 7.12 ( $p<0.001$ ), LAB 6.97 vs. 6.07 ( $p<0.001$ ) and ADH\_FU 66.5 vs. 73.6 ( $p<0.001$ ), respectively. The percent of patients who were given antidiabetic treatment in agreement with the guidelines in PRE and POST were similar (50% vs 54%, respectively,  $p=0.22$ ). However, the percent of patients who were given antihypertensive treatment (79% vs. 87%,  $p=0.001$ ) and antilipid treatment (87% vs. 93%,  $p=0.005$ ) in agreement with the guidelines increased significantly in POST when compared to PRE. Correlation coefficients ( $r$ ) between the score of knowledge and ADH\_FU score and the percent of patients treated in agreement with the guidelines, were found to be between -0.093 and +0.152 (all  $p$  values  $>0.05$ ).

**Conclusion:** Adherence of physicians to DM guidelines has shown an increase in many aspects of patient management following the implementation of awareness activities. However, surprisingly, no correlation could be detected between the knowledge of physicians and adherence to guidelines. This finding led us to consider that, the level of adherence to guidelines is a matter of behavior rather than a matter of knowledge. Therefore, we suggest that, activities targeting to increase the adherence to guidelines should focus not just to increase the knowledge, but mainly to change the attitude of physicians.

## 997

### Evaluation of the effectiveness of a 10-day structured diabetes education program for geriatric nurses - a prospective controlled trial

A. Bahrman<sup>1</sup>, E. Hölscher<sup>2</sup>, K. Hodeck<sup>3</sup>, S. Weyerer<sup>4</sup>, P. Oster<sup>2</sup>, W.G. Daniel<sup>1</sup>; <sup>1</sup>Internal Medicine 2, Friedrich-Alexander University, Erlangen, <sup>2</sup>Center of Geriatrics at the University of Heidelberg, Bethanien Hospital, <sup>3</sup>Institute for Innovative Health Management (IIGM), Berlin, <sup>4</sup>Institute for Mental Health-ZI, Mannheim, Germany.

**Introduction:** Up to 2008 there were no evaluated diabetes education programs for geriatric nurses available in Germany. Therefore, the Working group of the German Diabetes Association "Diabetes and Geriatrics" in cooperation with an institute for health management, set up the 10-day diabetes education program for geriatric nurses (DPFK) based on a written curriculum.

**Methods:** The program is split in 10 education days (every 2 weeks). The program focuses on the field of diabetes, nursing and quality management. Education units are f.ex. pathophysiology of diabetes, self-monitoring, diabetes therapy, techniques of insulin injection, diabetes complications, guidance of patients to learn autonomous insulin injection. The aim was to evaluate the effect of the standardized education program for geriatric nurses on their diabetes knowledge using standardized multiple choice questionnaires before (t1), during (t2), at the end (t3) and 3 months after (t4) participation in the education program. High scores in the multiple choice tests reflect better diabetes knowledge of the geriatric nurses (maximum score 75 points, Cronbachs alpha 0.82, mean item difficulty 0.65 T1). The present trial was a prospective randomised trial with one intervention group and two control groups (Internal control group: geriatric nurses working in the same nursing home/ambulatory care as the intervention group participant. External control group: geriatric nurses working in another nursing home/ambulatory care as the intervention group participant).

**Results:** Overall 81 geriatric nurses completed the study (48 intervention group participants, 28 internal control group participants and 15 external control group participants). There were no differences in diabetes knowledge comparing baseline skills of intervention group, internal and external control group participants (see Table 1). Intervention group participants improved their diabetes knowledge significantly. Interestingly, geriatric nurses out of the internal control group improved their diabetes knowledge from T1 to

T4 too, while participants of the external control group did not. These results have been expected, as firstly the concept of the structured education program for geriatric nurses was not only to improve diabetes knowledge of participants but also to change structure and process quality within the nursing homes/ ambulatory care services itself.

**Conclusion:** To summarize, participation in the structured education program was effective in improving diabetes knowledge in geriatric nurses and to change process and structure quality in nursing homes/ ambulatory care services significantly.

Results in diabetes knowledge (points in multiple choice test  $\pm$  SD) of the geriatric nurses

	T1	T2	T3	T4	p-value T1 vs. T4
Intervention group participants (n=48)	27.9 $\pm$ 6.9	39.4 $\pm$ 8.0	58.1 $\pm$ 8.8	59.3 $\pm$ 9.0	<0.001
Internal control group (n=28)	27.1 $\pm$ 9.4	34.8 $\pm$ 12.8	36.8 $\pm$ 14.7	44.0 $\pm$ 17.1	<0.001
External control group (n=15)	30.9 $\pm$ 8.9	30.8 $\pm$ 8.8	35.0 $\pm$ 13.2	33.7 $\pm$ 14.5	0.39
p- values intervention vs. internal control group	0.69	0.1	<0.001	<0.001	-
p-values intervention vs. external control group	0.19	0.001	<0.001	<0.001	-
p- values internal vs. external control group	0.21	0.29	0.70	0.06	-

### Use of contraceptives and glucose control in women with type 1 diabetes mellitus

C. Kellner, G. Wolf, U.A. Müller;  
Universitätsklinikum Jena, Germany.

**Background and aims:** Some women with type 1 diabetes mellitus experience worsening of metabolic control before the menstrual period, with a higher appearance of hypo- and hyperglycaemia. Indeed, patch-clamp-analysis has shown an influence of sex hormone fluctuation of glycaemic control. In a detailed German diabetes teaching and treatment program, women with type 1 diabetes are warned about the higher risk of ketoacidosis and hypoglycaemia before menstrual period. They also cover about the possible benefit from using contraceptives to stabilise blood glucose before menstruation. Therefore this study was designed to investigate the association of using contraceptives with lower blood glucose and less acute complications.

**Materials and methods:** Included were women with type 1 diabetes mellitus, aged between 15-50 years, a minimum duration of diabetes of 6 months and a visit in an university hospital (in- and outpatients) between 01.01.1990-01.02.2011. 6.255 visits of patients meet the inclusion criteria. Excluded were all visits without an HbA<sub>1c</sub>-value, a missing medical history, pregnant women, women in lactation and unclear diabetes-type. After exclusion criteria 3.732 visits could be analysed. The data were obtained from the electronic patient record form EMIL \*. The HbA<sub>1c</sub> value was DCCT adjusted (DCCT mean normal range: 5.05%). Use of contraceptives included injectable or oral contraceptives, hormone containing intrauterine device, hormonal contraceptive vaginal ring and contraceptive patch. Severe hypoglycaemia defined as glucagon injection or glucose i.v. was reported as episodes per 12 months. Ketoacidosis is defined as an acute hyperglycaemia with acidosis, which led to hospitalisation.

**Results:** 3321 visits from patients had no use of contraceptives, 411 visits with contraceptives could be identified. Patients with contraceptives were younger (32 vs. 36y,  $p < 0.001$ ), had a lower duration of diabetes (15 vs. 16y,  $p < 0.001$ ), fewer severe hypoglycaemia (0.11 vs. 0.15 episodes per year,  $p < 0.001$ ) and no ketoacidosis (0 vs. 0.04 episodes per year,  $p < 0.001$ ). In a regression analysis with HbA<sub>1c</sub> as a fixed variable and the independent variables age, duration of diabetes, use of contraceptives and number of blood glucose self-monitoring per / week, 2% of the variance in HbA<sub>1c</sub> was determined by age ( $p = 0.001$ , positive association) and diabetes duration ( $p = 0.03$ ; positive association). Use of contraceptives and blood glucose control had no significant association of HbA<sub>1c</sub> in the regression analysis. With regard to severe hypoglycaemia showed no significant associations with age, diabetes duration, blood glucose self-monitoring per week, use of contraceptives or the HbA<sub>1c</sub> value. Four percent of the variance of ketoacidosis has been declared in the regression analysis by a high HbA<sub>1c</sub> ( $p = 0.001$ , positive association). No significant association remained blood glucose self-monitoring per week, duration of diabetes, contraceptive use and age.

**Conclusion:** The use of contraceptives was not related to HbA<sub>1c</sub> or acute complications such as ketoacidosis or severe hypoglycaemia.

### Young adult diabetes care in the west of Ireland: challenges and opportunities

R. Casey<sup>1</sup>, M. O Hara<sup>1</sup>, A. Cunningham<sup>1</sup>, M. Bell<sup>1</sup>, H. Burke<sup>1</sup>, D. Wall<sup>2</sup>, R. Geoghegan<sup>3</sup>, L. Hynes<sup>4</sup>, B. McGuire<sup>4</sup>, M. Gately<sup>1</sup>, S.F. Dinneen<sup>1,5</sup>;  
<sup>1</sup>Endocrinology and Diabetes Centre, Galway University Hospital, <sup>2</sup>School of Mathematics, Statistics and Applied Mathematics, National University of Ireland, <sup>3</sup>Paediatrics, Galway University Hospital, <sup>4</sup>School of Psychology, National University of Ireland, <sup>5</sup>School of Medicine, National University of Ireland, Galway, Ireland.

**Background and aims:** The management of young adults with type 1 diabetes poses a number of challenges for both healthcare workers and healthcare organisations. Despite the establishment of a dedicated Young Adult Diabetes Clinic at our University Hospitals in 2005, healthcare professionals do not feel they are impacting on attendance rates and diabetes outcomes among this group and hence an audit of the service was conducted using

the Department's clinical information system and Emergency Department (ED) records.

**Materials and methods:** The reported data are expressed as percentages, means ( $\pm$  standard deviation, SD) unless other stated as the median and range. One-way ANOVA, two-sample t-tests, chi-square tests and Spearman and Pearson's correlations were used to determine association and comparisons between groups.

**Results:** Patients with type 1 diabetes referred to our service aged between 18–25 years before October 2011 were included in this study. The mean ( $\pm$  SD) age of the group ( $n = 137$ ) was 22 years ( $\pm 1.96$ ), 51.6% were male, 45.3 % were living with type 1 diabetes for at least 10 years. The average of all HbA<sub>1c</sub> measurements over 24 months was 81mmol/mol (9.6%). Diabetes complications were documented in 32.1% with retinopathy occurring in 19%. On average these young people were offered 7 clinic appointments in a 24 month period but on average only attended 4 (SD = 3.1). If a patient had not attended a clinic in over two years they were listed as a 'defaulter', 12.4% met these requirements. Unfortunately, 1 of the young adults died during the audit period. Patients who frequently missed clinics had more nurse contacts ( $p < 0.01$ ). ED admissions for both Diabetic Ketoacidosis (DKA, excluding those newly diagnosed) and hypoglycaemia were analysed in a subgroup of patients ( $n = 65$ ) who live within 80km of the base hospital. A total of 74% attended the ED at least once, 46% had 2 or more attendances and 26% had 3 or more. The average length of stay for patients admitted with DKA or severe hypoglycaemia was 2 days. DKA was the cause for ED attendance in 55.4%, 4.6% attended due to a hypoglycaemic event and 13.8% attended with separate hypoglycaemia and DKA episodes. There was no relationship between ED attendance and complication rates ( $p = 0.56$ ), missed clinic appointments ( $p = 0.33$ ) or HbA<sub>1c</sub> ( $p = 0.2$ ). Longer duration of illness was associated with more frequent ED attendances for hypoglycaemia ( $p < 0.01$ ).

**Conclusion:** Our results highlight the challenging issues posed by current healthcare utilisation in this patient group and the extra workload created through missed clinic appointments. We believe a different approach is required emphasising an organisational change that adapts to patient behaviour in young adults with type 1 diabetes.

## 1000

### A brief hospitalisation as an opportunity to improve diabetes control

Y. Bar-Dayán<sup>1</sup>, M. Boaz<sup>2</sup>, T. Chaïmy<sup>3</sup>, Z. Matas<sup>3</sup>, Z. Landau<sup>1</sup>, J. Wainstein<sup>1</sup>;

<sup>1</sup>Diabetes Unit, <sup>2</sup>Epidemiology and Research Unit, <sup>3</sup>Laboratory Unit, Wolfson Medical Center, Holon, Israel.

**Background and aims:** Poorly controlled hyperglycemia is associated with increased morbidity and mortality in hospitalized patients. Based on the view that hospitalization provides a window of opportunity to improve patient care and health status, a comprehensive program for treating hospitalized diabetic patients (PTHDP) was initiated. This study assessed the effectiveness of the PTHDP program.

**Materials and methods:** Pre-test post-test design. In the pre-intervention period (August–December 2007), as the first step of HDP an institution-wide blood glucose monitoring system was introduced in August. The remaining program components were introduced in January 2008, including implementing a hospital care protocol based on the 2007 American Diabetes Association Standards. PTHDP relies on a multidisciplinary team, which participates in patient care and arranges continuing care following discharge. Central to PTHDP was measuring hemoglobin A1C and albuminuria, and comprehensive patient education prior to discharge. The study ran from January 2008 through–October 2011.

**Results:** During follow-up, more than 600,000 blood glucose tests were performed with a mean value of  $186.2 \pm 89.7$  mg/dL. Glucose values declined from  $196.4 \pm 98.4$  mg/dL pre-PTHDP (August–December 2007) to  $174.5 \pm 82.0$  mg/dL post-PTHDP (January–October 2011) ( $p < 0.0001$ ). A significant, inverse association between blood glucose values and time was detected, indicating a reduction in mean blood glucose levels over time in hospitalized patients, concomitant with the introduction of the PTHDP. Blood glucose values declined over time after controlling for age, sex, and type of department. Prevalence of glucose values lower than 60 mg/dL declined from 2% to 1.3% ( $p < 0.004$ ). Prevalence of glucose values  $\geq 300$  mg/dL declined from 13.6% to 8.4% ( $p < 0.0001$ ). Concomitantly, a significant increase in the proportion of in-target values of 80–180 mg/dL was observed, increased from 47.7% to 58.1% ( $p < 0.0001$ ). Comparing the internal medicine to the surgical departments (excluding intensive care units) mean blood glucose values were significantly higher in internal medicine departments  $189.1 \pm 92.0$  mg/dL compared to  $177.3 \pm 79.4$  mg/dL ( $p < 0.0001$ ). Significantly more hypogly-

cemic events occurred in internal medicine departments 1.5% versus 0.7% ( $p < 0.0001$ ), and being in an internal medicine department increased the risk of hypoglycemic events by factor of 2. Hyperglycemic events were more common in internal medicine departments 11.5% versus 7.7% ( $p < 0.0001$ ); and being in an internal medicine department increased the risk by 57%. A significantly greater proportion of blood glucose values were within target values in surgical units 58.6% vs. 51.4%, respectively ( $p < 0.0001$ ). Blood glucose values, hyperglycemic and hypoglycemic events remained higher in internal medicine compared to surgical departments and in-target blood glucose values remained lower in internal medicine compared to surgical departments after controlling for age.

**Conclusion:** PTHDP improved inpatient glycemic control, which continued over time. More resources should be investigated in order to control diabetes in internal departments. The effect of this improvement on inpatient morbidity and mortality needs further follow-up.

## 1001

### Should we screen all acutely unwell patients for hyperglycaemia?

A prospective study at a medical acute admissions unit in the UK

S. Rokadiya, A. Nihat, M. Kostoula, F. Keane, B. Stroll, J. Patel, P. Pusalkar; Acute Assessment Unit, Watford General Hospital, UK.

**Background and aims:** There are currently no guidelines regarding testing capillary blood glucose or plasma glucose levels in acute medical inpatients, nor is there a national screening programme for the diagnosis of diabetes mellitus (DM) in the UK. Several observational studies have pointed to a strong association between hyperglycaemia and poor clinical outcomes including prolonged length of stay, infection, morbidity and mortality. Additionally, patients with impaired glucose tolerance are at increased risk of cardiovascular complications. We aimed to ascertain whether screening patients for hyperglycaemia during their acute hospital admission could identify patients either with DM or those at risk of developing DM.

**Method:** We prospectively analysed A&E, nursing and medical notes of 662 (338 male and 324 female, age range 16 to 96 years) unselected acute medical patients presenting to the Acute Admissions Unit (AAU) over a two-month period. All these patients were admitted in a non-ICU setting. We checked whether these patients had their capillary blood glucose and/or venous plasma glucose measured during the acute phase of their admission (from admission to 24 or 48 hours). Hyperglycaemia was defined as a blood glucose of  $>7.8$  mmol/L (ADA & AACE Consensus statement on inpatient glycaemic control, 2009).

**Results:** Of 662 patients, 159 were known to have DM (24%) and 503 had no history of DM. 140 patients with DM (89%) had their capillary glucose measured and 77 (55%) also had their plasma glucose measured. 19 patients (11%) with DM did not have their capillary blood glucose checked during the acute phase of their admission. Of the 503 patients with no history of DM, 209 (43%) had their capillary blood glucose measured. 37 (18%) of these had a capillary blood glucose of  $>7.8$  mmol/L and of these, 25 (64%) also had venous plasma glucose measurements. Interestingly, 7 (3.3%) patients with no history of DM had a capillary blood glucose of  $>11.1$  mmol/L and only 4 of these had their plasma glucose tested. Initial diagnoses for these patients were of acute coronary syndrome, pneumonia, cellulitis and drug overdose.

**Conclusion:** Only 43% of patients with no history of DM had their blood glucose checked. 18% of acute medical admissions in our cohort (with no previous history of DM) were found to be hyperglycaemic and 3.3% had a capillary blood glucose of more than 11.1 mmol/L. Follow-up of these patients is essential in order to differentiate between stress hyperglycaemia, impaired glucose tolerance and diabetes. In the absence of any robust guidelines, we suggest screening all acute medical patients with a simple capillary glucose measurement on admission. We also suggest that with no national screening programme for diabetes, emergency medical admissions should be used as a good opportunity to screen for diabetes.

## 1002

### Medication review in elderly patients discharged from hospital substantially decreased drug related problems

J. Hugtenburg<sup>1</sup>, A. Ahmad<sup>1</sup>, J.M. Dekker<sup>2</sup>, P.J. Kostense<sup>1</sup>, G. Nijpels<sup>1</sup>;

<sup>1</sup>Clinical Pharmacy, Vrije Universiteit Amsterdam, <sup>2</sup>Epidemiology and Biostatistics, Vrije Universiteit Amsterdam, Netherlands.

**Background and aims:** Older type 2 diabetes patients are using several drugs together. Drug related problems (DRPs) are common among elderly patients who are discharged from the hospital and using several drugs. Few interventions were reported to decrease DRPs in elderly people discharged from the hospital. We therefore studied the effect of medication review by the community pharmacist on the occurrence of DRPs in elderly persons.

**Materials and methods:** A randomized controlled study involving 340 patients. Community pharmacists were randomized to a control and an intervention group. Intervention pharmacists were instructed to perform a medication review, which include a medication analysis, treatment analysis, patient interview and counseling among patients aged over 60 years, using at least five prescription drugs and discharged from the hospital. Pharmacy technicians interviewed and counseled control and intervention patients in order to identify patient-perceived DRPs at baseline. They were instructed to interview and counsel patients at discharge, after three, six and nine months. DRPs in patients of control and intervention pharmacists were measured at baseline and at 12 months by two clinical pharmacologists.

**Results:** The total number of DRPs were 253 and 437 in the control group and 271 and 689 in the intervention group. The mean number of DRPs identified with the medication analysis decreased in the intervention group from 1.51 to 1.37. In the control group, the number of DRPs increased from 1.58 to 1.62. The mean number of DRPs identified with the patient interview in the intervention group decreased from 3.88 to 2.33. In the control group, the mean number of DRPs increased from 2.73 to 2.80. Subgroup analyses showed that the reduction of DRPs identified with medication analysis was significantly more pronounced among patients with hypertension ( $p = 0.011$ ) and heart failure ( $p = 0.001$ ).

**Conclusion:** The present study showed that pharmacist-led medication review is an effective method to reduce DRPs among elderly patients discharged from the hospital.

### Disparities of diabetes care in rural versus urban communities: more than a comparison

C. Burnot<sup>1</sup>, P. Vidal<sup>2</sup>, J. Lecadet<sup>2</sup>, J. Hazart<sup>2</sup>, S. Maqdasy<sup>1,3</sup>, L. Arnaud-Charra<sup>1</sup>, B. Roche<sup>1</sup>, F. Desbiez<sup>1</sup>, M. Batisse-Lignier<sup>1,3</sup>, I. Tauveron<sup>1,3</sup>;

<sup>1</sup>Departement of Diabetes, CHU, Clermont Ferrand, <sup>2</sup>Assurance-Maladie, Clermont Ferrand, <sup>3</sup>UMR CNRS 6293-Clermont University, INSERM U 1103, France.

**Background and aims:** The aim of our study is to compare the management of patients with type 2 diabetes in the Puy de Dome, area in France, to assess if there is any difference in terms of follow-up recommended by the High Authority for Health in patients living in rural communities versus urban ones.

**Materials and methods:** This is a retrospective case - control study. Inclusion criteria were: patients older than 50 years old, affiliated to the national health insurance, living in Puy de Dome, receiving at least one oral anti-diabetic medication or insulin repaid from April 1, 2010 to March 31, 2011. Rural population was defined by an access time to a hospital more than 1 hour away. Patients were matched for age and for each rural patient, 2 urban were included. The studied variables were HbA1c assays, fasting plasma glucose, lipid determinations, microalbuminuria, serum creatinine levels, ophthalmoscopy, cardiac evaluation and dental care. The number of general practitioner or diabetes consultations and hospitalizations were evaluated.

**Results:** Overall, 1089 rural patients and 2178 urban patients were included. Mean age was 68,0 years  $\pm$  9.8 and sex ratio was 1:4. 20.5% of rural patients versus 14.7% of urban patients did not have HbA1c any early evaluation ( $p < 0.01$ ). Among those who had an HbA1c, the average annual number of HbA1c evaluations was 1.6 for those living in rural areas and 1.7 for those living in urban areas ( $p < 0.01$ ). Furthermore, annual assays are significantly lower in rural areas vs urban zones concerning micro albuminuria (20.8% vs 29.1% respectively;  $p < 0.01$ ) fasting plasma glucose (64.2% vs 70.7%;  $p < 0.01$ ) and lipid assays (68.1% vs 75.7%;  $p < 0.01$ ) but no difference was noticed for

creatinine sampling (83.3 % vs 81.2 %). Moreover, medical follow up is significantly lower in rural areas: ophthalmologic screening (43.2% vs 49.8%;  $p < 0.01$ ) cardiac evaluation (36.8 vs 45.3%;  $p < 0.01$ ), dental care (28.3% vs 38.8%;  $p < 0.01$ ), general practitioner follow up (7.9 vs 8.3 consultations /year;  $p < 0.02$ ) or diabetes consultations (8.4% vs 13.2%;  $p < 0.01$ ). Further, all combined hospitalizations are significantly lower in rural zones (28.9% vs 31.1%;  $p < 0.02$ ). Sub-analysis of these parameters by gender and by age groups confirmed these results.

**Conclusion:** The care of diabetic patients in rural areas is lower than patients living in urban areas. Many factors can explain these discrepancies among which: a more difficult access to care and educational programs and lower income. These differences could still be higher with the spread of desertification of medical care in isolated areas. Thus, public health policies should focus on reducing geographical inequalities by promote medical proximity.

### Development and validation of a clinician-administered assessment tool that predicts self-efficacy in MDI management

I. Cranston<sup>1</sup>, J. Ryder<sup>2</sup>, C. Vogel<sup>3</sup>, C.G. Parkin<sup>4</sup>, D.A. Cavan<sup>2</sup>, R. Ziegler<sup>5</sup>, K. Barnard<sup>6</sup>, W. Koehler<sup>7</sup>, I. Vesper<sup>8</sup>, B. Petersen<sup>8</sup>, M. Schweitzer<sup>8</sup>;

<sup>1</sup>Queen Alexandra Hospital, Portsmouth, UK, <sup>2</sup>Royal Bournemouth Hospital, UK, <sup>3</sup>Internistisches Facharztzentrum, Langen, Germany, <sup>4</sup>CGParkin Communications, Inc., Boulder City, USA, <sup>5</sup>Diabetes Clinic for Children and Adolescents, Muenster, Germany, <sup>6</sup>University of Southampton, UK, <sup>7</sup>baseline statistics GmbH, Mannheim, Germany, <sup>8</sup>Roche Diagnostics GmbH, Mannheim, Germany.

**Background and aims:** Safe and effective diabetes therapy with multiple daily insulin injections (MDI) requires that patients possess both knowledge and confidence in their ability to count carbohydrates (CHO) and calculate bolus insulin doses. We developed a short, simple-to-administer questionnaire to assess baseline awareness of the skills required to effectively manage MDI therapy. We administered the tool to patients with type 1 (T1DM) and type 2 (T2DM) to evaluate its ability to predict self-efficacy in MDI management and to identify any correlations with glycaemic status.

**Materials and methods:** Baseline data were drawn from 93 T1DM and T2DM subjects enrolled in the Automated Bolus Advisor Control and Usability Study (ABACUS), a large, prospective, randomized, multi-national study of poorly controlled ( $\text{HbA1c} \geq 7.5\%$  / 58 mmol/l) MDI-treated patients. Characteristics were: mean (SD) age 41.1 (13.4) years, male 54.8%, diabetes duration 16.4 (10.5) years, MDI treatment duration 10.5 (7.7) years, and time since CHO training 40.1 (32.9) weeks. Subject history of MDI skills training was not captured. At screening, investigators administered the tool during a semi-structured interview to assess both carbohydrate counting skills and insulin dose adjustment skills. Tool scores were divided into 2 sub-categories: CHO assessment; and MDI assessment.

**Results:** Within this cohort, 54 (58.1%) subjects scored full competence (perfect score) in all questions in the CHO subset; whereas, only 26 (28.3%) achieved a perfect score in the MDI subset. Gender-related differences in scores were seen, with females showing a higher CHO-related perfect score (71.4% vs. 47.1%,  $p < 0.05$ ) but a slightly lower MDI-related perfect score (19.5% vs. 53.3%,  $p = \text{ns}$ ). A perfect score in either the CHO or MDI subset was associated with a lower mean (SD) baseline HbA1c: 8.57% (0.88) vs. 9.21% (1.55),  $p < 0.05$ ; and 8.32% (0.82) vs. 9.06% (1.33),  $p < 0.05$ , respectively. Subjects with perfect scores in both subsets ( $n=19$ ) had lower HbA1c values than those scoring perfectly in either one ( $n=35$ ) or no subset ( $n=39$ ): 8.24% (0.51) vs. 8.77% (1.0) vs. 9.21% (1.55), all  $p < 0.05$ . Better MDI assessment was associated with fewer blood glucose levels above 300 mg/dl ( $r = -0.34$ ).

**Conclusion:** These findings suggest that use of this simple questionnaire can predict self-efficacy and glycaemic outcomes in T1DM and T2DM patients treated with MDI. The differences seen in "fully competent" subjects suggest a level of self-management competence, which is associated with improved glycaemic outcomes that are similar to those seen with therapy change, such as commencement of CSII.

#### Boehringer Ingelheim employee study: a prospective epidemiological cohort study diabetes prevalence and association between impaired glucose metabolism and risk factors

M. Schneider<sup>1,2</sup>, S. Martin<sup>3</sup>, R.D. Hilgers<sup>4</sup>, K. Dugi<sup>5</sup>, C.W.v. Wolmar<sup>6</sup>, B. Haastert<sup>7</sup>, K. Kempf<sup>8</sup>;

<sup>1</sup>Medical Corporate Department, Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, <sup>2</sup>Mannheim Institute for Public Health, Medical Faculty Mannheim, <sup>3</sup>West-German Center of Diabetes and Health, Düsseldorf Catholic Hospital Group, <sup>4</sup>Department of Medical Statistics, RWTH-Aachen University, <sup>5</sup>Boehringer Ingelheim Pharma GmbH, Ingelheim, <sup>6</sup>Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, <sup>7</sup>mediStatistica, Neuenrade, Germany.

**Background and aims:** Epidemiologic studies in Germany have shown that in the age-group of 55-74 years old the prevalence of type 2 diabetes mellitus (T2DM) ranges about 16% and that glucose metabolism is disturbed in 40%. Since this problem not only has a health-economic impact but also impairs companies, we investigated by the Boehringer Ingelheim Employee Study the prevalence of T2DM in a representative cohort of the working population and associations between impaired glucose metabolism and cardiometabolic risk factors.

**Materials and methods:** Employees (>40 years; n=4326) of Boehringer Ingelheim Pharma GmbH & Co.KG were invited by the medical corporate department to participate in the prevention and health care program 'FIT IM LEBEN - FIT IM JOB'. The program offers every 3-5 years intensive health check-ups for free and advices for lifestyle changes. Cross-sectional analysis of baseline data was performed in order to describe the prevalence of T2DM (self-reported and/or HbA1c >6.5% and/or fasting glucose >126 mg/dl), hyperinsulinemia (fasting insulin >15 µU/ml), insulin resistance (HOMA index ≥2.6) and metabolic syndrome (according to the definition of the International Diabetes Federation (IDF)). Associations had been analyzed by Pearson correlation and differences between subgroups had been determined using t-test and odds ratios (OR) with 95% confidence intervals (CI).

**Results:** 90% of employees (n=3907; 54% men, mean age 47 ± 6 years) joined the programme. T2DM was prevalent in 15%, hyperinsulinemia in 12% and insulin resistance in 23%. Fasting insulin (r=0.396 and r=0.387; respectively, p=0.0001 each) were significantly correlated with body mass index and waist circumference. In persons with the metabolic syndrome or HbA1c above 6.5% fasting insulin and HOMA index were significantly elevated (p<0.0001 each) compared to the remaining cohort. In case of insulin resistance the risk for metabolic syndrome (OR 7.8 [6.0; 10.0]), hypertension (OR 3.0 [2.4; 3.9]), hypertriglyceridemia (OR 4.0 [3.2; 5.0]), hypercholesterolemia (OR 1.3 [1.1; 1.7]), increased intima media thickness (OR 2.6 [1.4; 4.7]) and cardiovascular diseases (OR 1.3 [1.0; 1.7]) was significantly increased.

**Conclusion:** Impairments in glucose and insulin metabolism and their associations with cardiometabolic risk factors are serious health problems in the working population. Since serious inducements for prevention programs by health insurances are lacking, companies should investigate in health care programs for their employees to reduce incidental wage costs. Due to their representative and high amount of participants and their intensive phenotyping the Boehringer Ingelheim Employee Study allows analyzing a variety of occupational health care questions.

*Supported by: Boehringer Ingelheim*

### 1007

#### Boehringer Ingelheim employee study: a prospective epidemiological cohort study Prevalence of and association between cardiometabolic risk factors and diseases

K. Kempf<sup>1</sup>, S. Martin<sup>1</sup>, R.D. Hilgers<sup>2</sup>, K. Dugi<sup>3</sup>, C.W.v. Wolmar<sup>4</sup>, B. Haastert<sup>5</sup>, M. Schneider<sup>6,7</sup>;

<sup>1</sup>West-German Center of Diabetes and Health, Düsseldorf Catholic Hospital Group, <sup>2</sup>Department of Medical Statistics, RWTH-Aachen University, <sup>3</sup>Boehringer Ingelheim Pharma GmbH, Ingelheim, <sup>4</sup>Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, <sup>5</sup>mediStatistica, Neuenrade, <sup>6</sup>Medical Corporate Department, Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, <sup>7</sup>Mannheim Institute for Public Health, Medical Faculty Mannheim, Germany.

**Background and aims:** Prevalence of overweight, obesity and reduced physical activity increased in recent years and supports the development of hypertension, dyslipidemia and type 2 diabetes mellitus, which are the main risk factors for cardiovascular diseases. Myocardial infarction and apoplexy not only impair quality of life and elevate the costs for the health care system but also burden companies by increasing costs for non-productive time and early retirement. However, valid and representative data about prevalence of cardiovascular risk factors in operational medicine are lacking so far.

**Materials and methods:** Employees (>40 years; n=4326) of Boehringer Ingelheim Pharma GmbH & Co. KG were invited by the medical corporate department to participate in the prevention and health care programme 'FIT IM LEBEN - FIT IM JOB'. The program offers every 3-5 years intensive health checkups for free and advices for lifestyle changes. Cross-sectional analysis of baseline data was performed in order to describe the prevalence of cardiometabolic risk factors and diseases. Differences between subgroups had been determined using t-test and odds ratios (OR) with 95% confidence intervals (CI).

**Results:** 90% of employees (n=3907; 54% men, mean age 47 ± 6 years) joined the programme. 40% of participants were overweight (body mass index (BMI) 25-30 kg/m<sup>2</sup>) and 16% obese (BMI >30kg/m<sup>2</sup>). Fitness was below standard (= lower tertile) in 31%. Prevalence of cardiometabolic risk factors and diseases such as hypercholesterolemia was 61%, hypertension 35%, metabolic syndrome (according to the definition of the International Diabetes Federation (IDF)) 27%, hypertriglyceridemia 23%, insulin resistance 23%, diabetes mellitus 15%, hyperinsulinemia 12%, increased intima media thickness 11% and cardiovascular diseases (e.g. myocardial infarction, apoplexy) 16%. Overweight and obese subjects had significant higher waist circumference, HbA1c, blood pressure, triglycerides, total and LDL cholesterol, intima media thickness and lower HDL cholesterol (all p<0.0001). Prevalence of diabetes mellitus significantly increased the risk for plaques within the Aorta abdominalis (OR 1.7 and CI [1.2; 2.4]), within the Aorta carotis (OR 3.4 [2.5; 4.6]) or stenoses therein (OR 8.3 [3.1; 22.5]).

**Conclusion:** The Boehringer Ingelheim Employee study demonstrates that the prevalence of cardiometabolic risk factors and diseases is a serious problem in the group of employees. Since risk factors can be reduced by lifestyle changes and by offering prevention programs, companies have the opportunity not only to increase the quality of life of their employees but also to reduce incidental wage costs.

### 1008

#### The optimal cut-off value of waist circumference based on insulin resistance and visceral fat thickness in Korean type 2 diabetes

J. Lim<sup>1</sup>, Y. Choi<sup>2</sup>, E. Lee<sup>1</sup>, K. Huh<sup>2</sup>;

<sup>1</sup>Yonsei University College of Medicine, <sup>2</sup>Huh's Diabetes Center and the 21 Century Diabetes and Vascular Research Institute, Seoul, Republic of Korea.

**Background and aims:** Central obesity is an important contributor to the development of metabolic syndrome and cardiovascular diseases (CVDs). In addition, visceral fat thickness (VFT) is known to be a reliable index for detecting diabetic patients who are at high risk of CVDs. However, there was an paucity of data on the appropriate cutoff point of waist circumference (WC) associated with metabolic risk factors, mainly targeted at type 2 diabetes. The aim of this study is to investigate the optimal cutoff value of WC for visceral obesity in type 2 diabetes.

**Materials and methods:** We evaluated 6,579 diabetic patients (male 3,394, female 3,185, mean age 58.03 ± 10.64 yr) who visited our Diabetes Center from Jan 2003 to Jun 2009. WC was measured at the midpoint between the lower

rib and the iliac crest, and insulin sensitivity was assessed by a rate constant for plasma glucose disappearance (*Kitt* %/min) using insulin tolerance test. The presence of visceral obesity, which was measured by ultrasonography, was defined as VFT of more than 47.6 mm and 35.5 mm in men and women, respectively, according to the criteria for diabetic patients as described by Kim et al. Statistic analysis was performed using ROC curve.

**Results:** The optimal cutoff point of WC for identifying two or more metabolic components was 87 cm for men and 81 cm for women. Moreover, these cutoff points had a higher association with the degree of visceral obesity in subjects with insulin resistance (the lowest tertile of *Kitt*) than insulin sensitive subjects (the highest tertile of *Kitt*).

**Conclusion:** Our results suggest that the optimal cutoff values of WC for insulin resistance and visceral obesity in Korean type 2 diabetes should be reestablished.

## 1009

### Long term projection of diabetes-related complications and life expectancy in China

G. Ning<sup>1</sup>, L. Wang<sup>2</sup>, Y. Jiang<sup>2</sup>, Y. Li<sup>2</sup>, N. Lund<sup>3</sup>, F. Sun<sup>4</sup>, Y.-F. Bi<sup>1</sup>, Y. Xu<sup>1</sup>, L. Wang<sup>2</sup>;

<sup>1</sup>Department of Endocrine and Metabolic Diseases, Ruijin Hospital, Shanghai, <sup>2</sup>National Center for Chronic and Noncommunicable Disease Control and Prevention, Beijing, <sup>3</sup>Novo Nordisk, Copenhagen, Denmark, <sup>4</sup>Novo Nordisk China Pharmaceuticals Ltd, Beijing, China.

**Background and aims:** The Chinese government has a target of increasing life expectancy by one year by 2015 with the completion of the Twelfth Five-Year-Plan for national health development of the People's Republic of China. The China Non-communicable Chronic Disease (NCD) Surveillance revealed high prevalence of diabetes in China (9.7%) equal to 93 million people. IDF projects that this number will rise to 129.7 million in 2030. This increase in the number of people living with diabetes can put the life expectancy improvement target at risk. The burden on the Chinese healthcare system is expected to be significant, if efforts to contain the disease are not made. We attempt to estimate what these effects could be of limited additional intervention compared to meeting glycaemic targets at different level of success.

**Materials and methods:** For the analysis, the CORE Diabetes Model with China-specific modifications was used. The patient cohort used was based on the diabetes sub-population of the China NCD Surveillance supplemented with data from the observational studies A1chieve and DiabCare where data from the NCD Surveillance was not available. In addition to measures of glycaemic control, the clinical inputs were as follows (mean (sd)): SBP 144 mmHg (25.1), TChol 4.5 mmol/L (1.3), HDL 1.06 mmol/L (0.32), LDL 2.57 mmol/L (0.87), Trigs 2.09 mmol/L (2.27), BMI 25.3 kg/m<sup>2</sup> (3.83) and 27.6% smokers. Mean age was 54.4 years. 63.9% were newly diagnosed. 56% were male. The analysis was based on a closed cohort with no dynamic effects of increased incidence. The modelling time horizon was 25 years and a discounting rate of 3% was used on both clinical and economic parameters.

**Results:** Achieving a glycaemic target of HbA1c < 7.0% for half the population leads to an improvement in life expectancy of around half a year for both gender. Significant improvements, particularly for micro-vascular complications are identified. Given the relatively young age of the cohort and the large share of newly diagnosed there are still benefits of improved treatments beyond the modelling time horizon, as 22% and 30% of men and women respectively were alive at the end of the 25 years in the baseline analysis with 3–5% percentage points more in the improved treatment scenarios. Further reductions are seen if 75% of the population reach the treatment target. Detailed results are shown in the table.

**Conclusion:** Even moderate improvements in glycaemic control can reduce diabetes related complications - particular micro-vascular complications - increase life expectancy and improve quality of life for people living with diabetes in China.

	Male No additional treatment	Male 50% to HbA1c<7.0%	Male 75% to HbA1c<7.0%	Female No additional treatment	Female 50% to HbA1c<7.0%	Female 75% to HbA1c<7.0%

## 1010

### Physical activity patterns and their metabolic influence in Transylvanian, Romanian type 2 diabetic patients

M.I. Szabo<sup>1,2</sup>, R. Balogh<sup>2</sup>;

<sup>1</sup>Diabetes, Medical and Pharmaceutical University, <sup>2</sup>Diabetes, Emergency County Clinic, Tg Mures, Romania.

**Background and aims:** The beneficial effect of physical activity in type 2 diabetes, and in preventing cardiovascular morbidity is very well established, and exercise guidelines for that category of patients widely exist, however the implementation of this guidelines among diabetic patients is very low, and varies with different habits and barriers in different regions. Our goal was to establish the exercise patterns of type 2 diabetes patients in our region (after our knowledge no such study has so far been done), and their influence on the metabolic outcomes, in order to be able to develop a specific exercise strategy for our patients.

**Materials and methods:** The cross sectional observational study was conducted in Tg Mures, a representative Romanian, Transylvanian day care centre, with patients coming urban and rural environment. A group of 412 type 2 diabetes patients were randomly selected. We recorded socio demographic, anthropometric, diabetes related data, presence of complications, and HbA1c values. Habits of exercise were recorded in detail using a questionnaire, referring to duration, intensity, type, frequency of activity. We introduced the notion of mean physical activity index (PAI)/week (taking in account duration and energy cost of activity) to compare and correlate the different exercises. Effort was divided in 4 categories: walking (1), gardening/working on field type activity (2), profession related activity (3) and sports or leisure physical exercise (4).

**Results:** Women represented 54.3% of the study population; mean age was 63.17±10.05 years. Only 13.6% of patients had an activity level equivalent or greater to that recommended in guidelines (150 min moderate exercise/week). The distribution of activity type chosen by patients was walking: 55.1%, gardening: 31.3%, professional activities: 10.3%, sports only in 3.3% of cases. But the PAI/week was the highest in the 2. and 3. group (p<0.001, CI 0.45-0.25). Men, rural habitants, and those with lower educational level (p<0.01) had higher PAI. The index was inversely correlated with age, BMI (r = -.202, resp -.208, p<0.001). Only the highest PAI quartile had significantly lower HbA1c levels (7.28 vs. 7.92, p<0.01). The PAI was lower in those with cardiovascular comorbidities (p<0.001), but was independent from micro-vascular complications.

**Conclusion:** Despite of exercise recommendations only a small proportion of patients are achieving the goal, compliance is far better with domestic or professional activities than with sports; women, patients with higher educational level, and those living in town are less active. Patterns of activity in our region are different, and there is the need to develop specific, individualised exercise strategies for our patients.

## 1011

**Correlates of physical fitness in patients with type 2 diabetes**J. Puder<sup>1</sup>, L. Allet<sup>2</sup>, F. Amati<sup>3</sup>, J. Barral<sup>3</sup>, P.-M. Marques-Vidal<sup>1</sup>, O. Giet<sup>1</sup>;<sup>1</sup>CHUV, Lausanne, <sup>2</sup>HUG, Genève, <sup>3</sup>UNIL, Lausanne, Switzerland.

**Background and aims:** Several fitness outcomes such as muscular strength, aerobic fitness or walking speed are important predictors of mortality and morbidity. We tested if different physical fitness measures correlated to classical morbidity and mortality outcome measures such as BMI, cardiovascular risk factors, metabolic control, diabetic complications and socioeconomic status in patients with type 2 diabetes.

**Methods:** Seventy-seven patients from 8 DIAfit centers in the French part of Switzerland were recruited to participate in the study. Hypoglycemic episodes, medication use, BMI, blood pressure, vibration threshold (a measure of neuropathy), lipid profile and HbA1c were assessed. Educational level (EL) was used as proxy for socioeconomic status. We tested the following fitness outcomes: Aerobic fitness (maximal cycle ergometry; W), walking speed (required time for 10m walk; sec), functional lower limb muscle strength (required time for chair stand; sec), balance (maximal time for unipedal stand; sec) and flexibility (finger-floor distance; cm).

**Results:** All seventy-seven patients (age  $60.2 \pm 10.3$  yrs (range 30–85 yrs), 58% female, diabetes duration  $9.3 \pm 7.2$  yrs) participated in the study. 6% had at least weekly hypoglycemic episodes. 77% had treated hypertension, 62% had treated dyslipidemia. For 3 patients, falls have been recorded in the last year. The BMI was  $31.8 \pm 4.9$  kg/m<sup>2</sup>, the vibration score  $5.5 \pm 1.9$  and the HbA1c  $7.3 \pm 1.7\%$ . 41% of the participants had a high, 37% a middle and 22% a low EL. Among all 5 fitness measures, age was inversely correlated with aerobic fitness and balance ( $r = -0.3$ ,  $p = 0.02$  and  $-0.4$ ,  $p = 0.001$ ). Furthermore, aerobic fitness was higher in men compared to women ( $p = 0.0001$ ). In this population, BMI, the vibration threshold, HbA1c levels, the presence of hypertension or of dyslipidemia were not associated with physical fitness measures except for a positive correlation between the vibration sensibility and balance ( $r = 0.3$ ,  $p = 0.04$ ). In contrast, EL was associated with aerobic fitness ( $r = 0.48$ ,  $p = 0.001$ ), muscular strength ( $-0.4$ ,  $p = 0.006$ ) and walking speed ( $-0.47$ ,  $p = 0.001$ ).

**Conclusion:** In this population of mostly treated patients with type 2 diabetes, classical morbidity and mortality outcome measures were not associated with different physical fitness measures. In contrast, socioeconomic status was highly associated with physical fitness measures in these patients. These findings provide insight into different modulable clinical pathways with the perspective to further improve outcomes.

Clinical Trials Registration Number: NCT01289587

## 1012

**Burden of disease and out-of-pocket expenditures associated to type 2 diabetes and its complications in Argentina**J.F. Elgart<sup>1</sup>, J.E. Caporale<sup>1</sup>, L. Gonzalez<sup>1</sup>, J.L. De la Fuente<sup>2,3</sup>, M.C. Camillucci<sup>2,3</sup>, J.J. Gagliardino<sup>1</sup>;

<sup>1</sup>CENEXA - Centro de Endocrinología Experimental y Aplicada (UNLP-CONICET La Plata), La Plata, <sup>2</sup>Fundación para las Ciencias Biomédicas de Córdoba, <sup>3</sup>Hospital Privado Centro Médico de Córdoba, Argentina.

**Background and aims:** To assess a) the economic impact of diabetes on quality of life, disabilities and health utilities, on the income, employment, education and property of patients and their families, and b) the efficiency of medical care received by people with type 2 diabetes (T2DM) with and without complications in Argentina; c) to compare these costs with those recorded in people without diabetes.

**Methodology:** Case-control study comparing cases with T2DM with or without chronic micro- and macrovascular complications and controls without diabetes (paired by age and gender) and social contexts. Data were obtained by telephone interviews (March to April 2011) using the same questionnaire except for a few questions related to diabetes treatment. Interview data were supplemented with data obtained from clinical records from each interviewee to fully describe the subjects' resources utilization and costs of care. Data were statistically analysed using the Statistical Package for Social Sciences (SPSS) version 15. Differences in means and proportions were verified using Student's t-test, ANOVA and Chi2. The study had ethical clearance and all subjects provided oral informed consent.

**Results:** We interviewed 1908 patients (954 non diabetic controls, 477 people with T2DM without complications, and 477 people with T2DM and complications), mostly female (52.4%, 56.6% and 50.5%, respectively). Diabetes duration in the group with complications was significantly higher than in the

group without complications ( $8.3 \pm 8.6$  vs.  $11.1 \pm 9.0$ ). People with T2DM with complications had significantly lower salaries; a lower percentage of people attained university degree and showed higher medical resource consumption. They also lost more working days (14.3) than those with T2DM without complications (8.6) or without T2DM (8.8).

**Conclusion:** This is the first report showing objectively the heavy burden of diabetes and its complications for the patient, his/her family, the health system and society overall in a Latin American country. The data are a serious warning for health care authorities to strengthen the implementation of prevention strategies to reduce this burden.

Main results			
Parameter	Control	T2DM without complications	T2DM with complications
Age (yrs; mean $\pm$ SD)	60.6 $\pm$ 11 (954)	61.2 $\pm$ 11.8 (477)	64.5 $\pm$ 8.7 #* (477)

## 1013

**Immediate feedback of HbA<sub>1c</sub> results to patients improves diabetes control and outcomes: a 12-month intervention in 10 sub Saharan African settings**E. Sobngwi<sup>1</sup>, N.M. Balde<sup>2</sup>, A. Camara<sup>2</sup>, J.-L. Nguewa<sup>3</sup>, S. Limen<sup>3</sup>, IA3 investigators;

<sup>1</sup>Institute of Health and Society, Newcastle University, Newcastle upon Tyne, UK, <sup>2</sup>Department of Endocrinology, CHU Donka, Conakry, Guinea,

<sup>3</sup>Department of Endocrinology, Yaounde Central Hospital, Cameroon.

**Background and aims:** The objective was to determine whether the introduction of routine affordable HbA<sub>1c</sub> determination with immediate feedback to patients and relevant education in an underserved population without any further intervention on drug supply would significantly improve diabetes control.

**Materials and methods:** We enrolled consecutive people with diabetes diagnosed at least one year prior to the investigation for a 12-month intervention where each participant is its own control. The study settings were 10 existing diabetes care centre in two countries, including 4 regional centres in Guinea and 6 regional centres in Cameroon. All participants had a baseline assessment of diabetes control and complications, and patient knowledge regarding diabetes and its care, a three-monthly assessment of diabetes control with immediate feedback to patient and provision of targeted education, until completion of the planned 12 months follow up. The intervention consisted of point of care measurement of HbA<sub>1c</sub> with immediate feedback to patient and provision of targeted education, in addition to usual care. Education is provided in the format of a one-to-one 10-minute education session with explanation about what HbA<sub>1c</sub> is, its clinical and prognostic meaning, and translation of measurement into average blood glucose value conducted before the routine follow up consultation.

**Results:** A total of 1349 were enrolled including 813 in Cameroon and 536 in Guinea. The mean age of the study population was  $56.2 \pm 12.6$  years and the mean duration of diabetes was  $7.4 \pm 6.3$  years. The study population was composed of 59.8% women in total. Baseline HbA<sub>1c</sub> was  $9.7 \pm 2.6\%$  in Guinea and  $8.6 \pm 2.5\%$  in Cameroon. The average one-year reduction in HbA<sub>1c</sub> was  $-0.8 \pm 2.3\%$  with 40% of the total sample who reduced their HbA<sub>1c</sub> by more than 1 point and 36% at 12-month versus 25% at baseline achieving the  $<7\%$

HbA1c target. The proportion of patients achieving the target changed from 10–39% at baseline across centres, to 19–56%. In parallel, 38 to 71% of the patients decreased their urinary albumin excretion within one year. There was on average a 0.5 to -12 mmHg decrease in systolic blood pressure across the centres. All reported changes in absolute and relative expression in HbA1c, blood pressure and urinary albumin excretion being significant.

**Conclusion:** Improving access to HbA1c point of care determination with immediate feedback to patient and provision of targeted education without additional intervention resulted in a significant improvement in diabetes control as well as blood pressure and urinary albumin excretion in patients with prior minimum one year regular follow up two sub Saharan African countries. These results suggest that the proposed intervention is potentially markedly cost saving.

*Clinical Trials Registration Number: NCT01460095*

## 1014

### Monitoring of diabetes trials and changes made to trial records through automated semantic web-mining

D. Cocker<sup>1</sup>, J. Lievens<sup>1</sup>, M. De Cré<sup>1</sup>, I. Gallen<sup>2</sup>;

<sup>1</sup>MDCPartners, Aartselaar, Belgium, <sup>2</sup>Wycombe Hospital, High Wycombe, UK.

**Background and aims:** There is a challenge to populate large clinical trials in diabetes. Poor enrolment and patient retention are often cited as major causes of study delay and failure. The obligation to publicly disclose trial information today offers the possibility to monitor trial plans and changes made to ongoing trials. Such data can enhance assumptions and feasibility evaluation of new trials. This paper evaluates the results of a robotic, semantic analysis of registered diabetes trials to determine geographic distribution of trial sites and assess changes to trials over time.

**Materials and methods:** We have developed a code-base that extracts data from multiple public databases pertaining to clinical and medical research. Using a medical ontology and natural language processing, resolution of inadequate registry fields is increased and data are semantically linked into one domain containing trials, researchers, organizations, drugs, and geographical information. We compared data sets from December 2008 and January 2012. Industry-sponsored trials recruiting at least 200 diabetes patients in December 2008 (228 trials) were evaluated for changes to individual trial records. An assessment was made of phase III trials for which 2 sites or more had been added according to the January 2012 registry.

**Results:** Diabetes trials are mainly conducted in North America, Western and Eastern Europe. Over the last 5 years, the share of sites opened in these “traditional” diabetes trial regions has remained stable (45, 19 and 10% of all diabetes sites opened), notwithstanding an increase in sites opened in other regions. Number of sites has tripled in East Asia and doubled in Japan (to reach 7.3% and 6.2% of all sites opened in 2011). The percentage of trial sites has also tripled in the Middle East (to 2.1% of all sites opened in 2011). In India, South-East Asia and Russia there has been a marked relative decrease (of at least 50%) in diabetes trial sites opened over the last 5 years. Assessment of changes made to a cohort of industry-sponsored trials shows that about 80% of these trials (186 out of 228) deviate from the initial stated targets for enrolment, study end or number of sites used. Most frequently, enrolment targets are increased (45% of trials increase enrolment by at least 5 patients) or study end date is delayed (in 41% of diabetes trials study end date is delayed by at least 3 months). In 20% of trial records, the site number is increased by at least 2 while the trial is running. When site number is increased, this can indicate an unexpected increase in enrolment need. A cohort of industry-sponsored trials was selected for which site number was increased between 2008 and 2012 and geographic distribution of the newly opened sites was assessed. While the new trial sites were spread over 73 different countries, there was a marked shift of research to sites in Spain, Italy, Belgium, Japan, Israel, Austria, Taiwan and Argentina (714, 700, 301, 314, 212, 185, 153 and 122 additional sites opened, respectively), suggesting these are preferred countries when sponsors face an increased enrolment need.

**Conclusion:** East Asia, Japan and the Middle East are increasingly involved in diabetes trials, while other “emerging” regions seem to lose terrain. In more than 40% of initial trial records final enrolment number or trial duration are underestimated. Some countries appear to be preferred when additional sites are required for a running trial.

## 1015

### Health care climate questionnaire: a useful tool to assess the health care provider approach as perceived by parents of children with diabetes

C.E. de Beaufort<sup>1,2</sup>, K. Lange<sup>3</sup>, S.E. Skovlund<sup>4</sup>, H. Hoey<sup>5</sup>, L. Castano<sup>6</sup>, H. Mortensen<sup>7</sup>, Hvidoere Study Group;

<sup>1</sup>DECCP, Clinique pédiatrique, Luxembourg, <sup>2</sup>Lcsb, University of Luxembourg, Esch sur Alzette, Luxembourg, <sup>3</sup>Department of Medical Psychology, Medizinische Hochschule, Hannover, Germany, <sup>4</sup>Novo Nordisk A/S, Gentofte, Denmark, <sup>5</sup>Trinity College, Dublin, Ireland, <sup>6</sup>University of Basque Country, Barakaldo, Spain, <sup>7</sup>Department of Pediatrics, Herlev Hospital, Denmark.

**Objective:** Previous studies have suggested that health care partnership supporting autonomy may improve outcome in patients with chronic illness. In the Hvidoere Study 2009, we analysed whether the health care climate perceived by parents, influenced wellbeing in parents and outcome in children.

**Methodology:** In this cross-sectional study, children with type 1 diabetes mellitus treated in 18 centres, (Australia, Europe, Israel, Japan and North America) aged <11 yrs and a diabetes duration ≥1 y, participated. Clinical characteristics of the children have been previously reported (n= 1133; female: 47.7 %; mean age 8.0 ± 2.1 y; mean diabetes duration 3.8 ± 2.1 y, CSII/ BBI 49.7%; CT 51.3%, overall mean HbA1c 8.0 ± 1.0% (64 mmol/mol)). The parents were invited to answer questionnaires, including the health care climate questionnaire (HCCQ) and the WHO-5. The HCCQ assesses parents' perception of an autonomy supporting versus controlling approach from the health care providers. They answered the five items on a 7-point Likert-type scale ranging from 1 to 7. WHO-5 is a validated tool to evaluate parental well being.

**Results:** Questionnaires were received from 1015 parents. The Cronbach alpha for HCCQ was 0.82. Relatively high scores were reported in all centres (mean: 6.2 ; range 5.0– 6.9) suggesting autonomy supporting health care. Outcome was not influenced by gender, age, diabetes duration nor diabetes treatment of the child. A weak negative association was found between HbA1c and HCCQ score (r= -0.081, p< 0.008). In those (n= 140) with HbA1c >9, 0%, lower HCCQ scores were found (6.0). WHO-5 score showed a significant relationship with HCCQ score: (r=0.145\*\* p < 0.001), with a lower wellbeing reported by parents with lower HCCQ scores.

**Conclusion:** HCCQ is a valid tool for parents of children with diabetes. Most parents in the Hvidoere centres report an empowerment and autonomy oriented partnership with diabetes teams. Wellbeing as evaluated through WHO-5 was positively associated with this autonomy supporting approach. Worse metabolic outcome seemed associated with lower autonomy support perceived by the parents. Whether these parents would benefit from a different support concept to improve metabolic outcome, requires further study.

## PS 085 Cost and quality of diabetes care

1016

### Use of diabetes nurse specialist driven telephone service during evenings, nights and weekends by patients attached to a diabetes specialist hospital

M. Due-Christensen, K.E. Nielsen, T. Almdal, V. Zoffmann;  
Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** Our hospital is a diabetes specialist hospital serving as an integrated part of the public hospital system treating approximately 3600 type 1 diabetes patients (T1D) and 2400 type 2 diabetes patients (T2D). A telephone service staffed with diabetes nurse specialists (DNS) is open for all patients during opening hours of the out-patients clinic. As supplement to the services provided in the out-patient clinic a DNS is on call after-hours 7 days a week concerning diabetes related problems considered critical by patients or their health care professionals. The DNS can, if needed, contact a consultant diabetologist. The aim of the present study was to review the service outside opening hours of the outpatient clinic, i.e. during evenings, nights and weekends concerning the number of calls, the sources and the purposes of the calls as well as the services provided.

**Materials and methods:** All calls to the on-call DNS outside opening hours of the outpatient clinic were registered prospectively by the DNS according to a predefined form in the period from January 21st to July 18th 2011.

**Results:** In total, 3197 calls were registered concerning 592 individual patients (56.4 % of these women), corresponding to approximately 10 % of the patients attached to the outpatient clinic. Age  $56.6 \pm 19.7$  years (mean  $\pm$  SD). 2175 (68 %) calls were related to patients with T1D and 836 (26.2 %) related to patients with T2D (of these 95.7 % were concerning patients treated with insulin). 186 (5.8 %) were related to patients with other types of diabetes. HbA1c  $8.8 \pm 1.9$  (mean  $\pm$  SD), which is significantly higher ( $p < 0.001$ ) than the mean HbA1c of all patients seen in our hospital  $8.1 \pm 1.5$  (mean  $\pm$  SD). 1368 (42.8 %) of the calls were initiated directly by the patients, 1637 (51.2 %) by health care professionals in primary care and 142 (4.4 %) by relatives and 50 (1.6 %) by other sources. Hyperglycaemia was the main purpose for contact corresponding to 1655 (51.8%) calls. Of these 1136 (68.6 %) were related to patients with T1D. The most often provided service was advice in relation to insulin dose adjustment i.e. in relation to hyper or hypoglycaemia or physical activity pertaining 2210 (69.1 %) calls. Of 17 potential admissions, 15 were avoided. One call only to the telephone service was made by 295 (49.8 %) of the patients, whereas 146 (24.7 %) called 2-4 times, 129 (21.8 %) called 5 - 29 times and 22 (3.7%) called 30 times or more (range 30 -162). Approximately 90% of the purposes for calling were considered relevant and related to diabetes by the DNS receiving the call. The DNS handled 3114 (97.4 %) of the calls without supervision from the diabetologist.

**Conclusion:** DNS-provided on-call telephone service outside outpatient opening hours is used by approximately 10 % of the population attached to a diabetes specialist hospital. The most frequent purpose of the calls related to advice on dose adjustment concerning hyperglycaemia. Fifteen admissions were avoided. The service is considered useful for the majority of patients. More investigation is needed concerning patients calling more than 30 times in 6 months in order to improve/learn more about the provision of service to these patients; moreover, a high number of calls came from health care professionals in primary care, suggesting a need for further education concerning diabetes in this sector.

1017

### Cost-effectiveness of intermediate care clinics for diabetes (ICCD): findings of a UK cluster randomised trial

A. Szczepura<sup>1</sup>, P. Saravanan<sup>1</sup>, D. Baines<sup>1</sup>, S. Petrou<sup>1</sup>, R. Crossman<sup>1</sup>, A. Hardy<sup>2</sup>, N. Raymond<sup>1</sup>, A. Wilson<sup>2</sup>, J.P. O'Hare<sup>1</sup>, ICCD Study Group;  
<sup>1</sup>Warwick Medical School, University of Warwick, Coventry, <sup>2</sup>Department of Health Sciences, University of Leicester, UK.

**Background and aims:** World-wide, healthcare systems are faced with an epidemic of type 2 diabetes. In the UK, clinical care is primarily provided by general practitioners (GPs) rather than hospital specialists. Intermediate care clinics for diabetes (ICCD) potentially provide a model for supporting GPs in their care of people with poorly controlled type 2 diabetes. This study aimed

to assess the cost-effectiveness of ICCD provision compare to usual hospital care for such patients.

**Materials and methods:** 49 practices in three English Primary Care Trusts (PCTs) in Coventry, Leicester and Warwickshire were randomised to usual care or access to an ICCD service. All suitable patients were invited to take part. Outcomes were measured after 18 months. The primary clinical outcome was 'combined control' - achievement of all three targets from NICE guidelines of HbA1c  $\leq 7.0\%$ , b.p.  $< 140/80$  mm Hg and cholesterol  $< 4$  mmol/l. Health related quality of life (HRQoL) was measured at baseline and 18 months using EQ-5D. ICCD costs were calculated to include staff, accommodation and consumables. Other NHS resource use was recorded via patient questionnaires. Costs and QALYs were discounted at a rate of 3.5%. Cost-effectiveness was assessed by comparing incremental costs and marginal benefits. Sensitivity analysis was undertaken.

**Results:** A total of 1,997 patients with type 2 diabetes were recruited to the trial. ICCD consultation costs were estimated at £104.33; use of case management increased referral rates and decreased unit costs. GP utilisation costs were higher in the ICCD group (mean £26.56 vs. £ 20.07,  $p = 0.012$ ) as were community clinic costs (£1.46 vs. £ 0.49,  $p = 0.025$ ). Total NHS resource use costs did not differ at the 5% level, whether or not ICCD costs were included. Follow-up data, collected for 1,280 (61%) showed a clinically important gain in combined control (14.3% for ICCD patients vs. 9.3%) despite low numbers of referrals to ICCD in two PCTs. After adjusting for confounding factors and clustering this difference was not significant ( $p = 0.059$ ). There was no significant difference in HRQoL between patient groups at baseline. An incremental cost-effectiveness ratio (ICER) of £7,778, following 1,000 replicated bootstraps, indicated that ICCD is marginally more expensive at producing health gain (EQ-5D) for patients. The cost-effectiveness acceptability curve (CEAC) similarly showed a low probability that ICCD is more cost-effective than standard care at the cost per QALY threshold usually employed by NICE (£30,000). A sensitivity analysis, excluding patients with hospital stay  $> 10$  days, demonstrated a 95.9% probability that the control group remains cost-effective at the £30,000 threshold.

**Conclusion:** Our results indicate that an ICCD service provides no direct cost saving relative to standard care. There is also no evidence that this service model is cost-effective relative to standard care (based on EQ-5D). However, use of case management can increase uptake which might improve cost-effectiveness. Development of a service model to achieve better outcomes for patients with poorly controlled diabetes remains a challenge.

### Diabetes care in a shared care project: trends and age differences in the period 1998-2008 (ZODIAC-19)

K.J.J. van Hateren<sup>1</sup>, I. Drion<sup>1</sup>, N. Kleefstra<sup>1</sup>, K.H. Groenier<sup>2</sup>, S.T. Houweling<sup>1</sup>, K. van der Meer<sup>2</sup>, H.J.G. Bilo<sup>1</sup>;  
<sup>1</sup>Diabetes Centre, Zwolle, <sup>2</sup>University Medical Center Groningen, Netherlands.

**Background and aims:** The Zwolle Outpatient Diabetes project Integrating Available Care (ZODIAC) study was initiated in 1998 to investigate the effects of shared care for patients with type 2 diabetes mellitus in the Netherlands, and to reduce the number of diabetes-related complications. Benchmarking the performance of diabetes care was and is an important aspect of this study. We aimed to investigate trends in diabetes care, within the ZODIAC study for a wide variety of quality indicators during a long follow-up period (1998-2008), with a special focus on different age groups.

**Materials and methods:** A dataset of quality measures is collected annually during the patient's visit to the practice nurse or general practitioner. Linear time trends from 1998-2008 were estimated using linear mixed models in which we adjusted for age and gender. Age was included in the model as a categorical variable: for each follow-up year all participants were categorised into the categories  $< 60$ , 60-75 and  $> 75$  years. Differences in trends between the age categories were investigated by adding an interaction term to the model.

**Results:** Table 1 presents the results of various quality measures for the total study group. All data are mean values or proportions together with their 95% confidence intervals. The number of patients who were reported to participate increased in the period 1998-2008 from 1622 to 27438. All quality indicators improved in this study, except for body mass index. The prevalence albuminuria decreased in an eleven-year-period from 42% to 21%. No relevant differences between the trends for the 3 age categories were observed.

During all years of follow-up, mean blood pressure and body mass index were the lowest and highest, respectively, in the group of patients <60 years (data not shown).

**Conclusion:** Quality of diabetes care within the Dutch ZODIAC study, a shared care project, has considerably improved in the period 1998–2008. There were no relevant differences between trends across various age categories. This study shows the great potential of intensive cooperation between primary and secondary health care.

## 1019

### The value of performance measurement in diabetes

S. Smith<sup>1</sup>, N. Shah<sup>2</sup>, K. Eggleston<sup>3</sup>, V. Montori<sup>1</sup>, J. Newhouse<sup>4</sup>, E. Berndt<sup>5</sup>; <sup>1</sup>Department of Internal Medicine, Mayo Clinic Rochester, <sup>2</sup>Health Care Policy & Research, Mayo Clinic Rochester, <sup>3</sup>Asia Health Policy Program, Stanford University, <sup>4</sup>Department of Health Care Policy, Harvard Medical School, Boston, <sup>5</sup>Applied Economics, MIT Sloan Management, Cambridge, USA.

**Background and aims:** Purchasers are using performance measures to design and implement incentives to improve quality of diabetes care. Haemoglobin A1c (HbA<sub>1c</sub>) has gained wide acceptance as a performance measure, usually based on a threshold value. The aim of this study was to test the assumption that better quality is consistent with better net value.

**Materials and methods:** Using data from Mayo Clinic Rochester's Electronic Management System, we identified 970 patients diagnosed with type 2 diabetes before 1 January 2005 who were continuous Mayo employees or dependents of employees from 1999 to their deaths or to 2009. We assess the net value of diabetes management, defined by whether the value of prevention of future mortality and morbidity exceeds the increase in costs of diabetes management. Using the United Kingdom Prospective Diabetes Study cardiovascular risk equations, we estimate the 10-year modifiable risk of coronary heart disease (CHD) or stroke for each patient. "Modifiable" risk holds constant the patient's age and duration of diabetes. We compared changes in these 10-year risks for nine "HbA<sub>1c</sub> cohorts" based on initial and final HbA<sub>1c</sub> values: <7%, 7 to 8.5%, and greater than 8.5%. Spending is for all medical care, related- unrelated to the diagnosis of diabetes, converted to constant 2009 dollars using GDP deflator.

**Results:** Estimated CHD risk improved, with all HbA<sub>1c</sub> cohorts experiencing a decrease except for patients with final HbA<sub>1c</sub> greater than 8.5%. All cohorts experienced small decreases in the estimated risk of fatal stroke. Mean annual inflation-adjusted spending for the care of patients with type 2 diabetes increased for all HbA<sub>1c</sub> cohorts, although those patients with HbA<sub>1c</sub> values under 7% in both time periods had one of the most modest increases (18%). Assuming a monetary value of \$200,000 for one life-year, net value was positive for all HbA<sub>1c</sub> cohorts except patients with poor control throughout (HbA<sub>1c</sub> greater than 8.5% in both time periods). The highest net value, of over

\$52,815, was for the cohort with the largest improvement in HbA<sub>1c</sub> (>8.5% to <7%). These results suggest good value for keeping patients below 8.5%. (Figure)

**Conclusion:** On average, the monetary value of the patients' improvements in cardiovascular risk exceeded health spending for cohorts with final HbA<sub>1c</sub> values less than 8.5%. While it may appear to be consistent with a threshold that could be used for determining pay-for-performance, it is a higher value than most stated guidelines and current measures for pay-for-performance. It suggests that other factors in the population are likely contributing to outcomes and are worthy of attention for improving value (e.g. access to care, smoking cessation, depression, comorbidities).

### Figure Net Value, by HbA1c in Final Period

## 1020

### The quality of care provided by Italian diabetes clinics to elderly patients with type 2 diabetes

R. Candido<sup>1</sup>, M.A. Pellegrini<sup>2</sup>, G. Felace<sup>3</sup>, M. Boemi<sup>4</sup>, A. Perrelli<sup>5</sup>, M.C. Rossi<sup>6</sup>, A. Nicolucci<sup>6</sup>, C. Giorda<sup>7</sup>; <sup>1</sup>Diabetes Centre, A.S.S. 1 Triestina, Trieste, <sup>2</sup>Diabetes and Metabolism Unit, A.O.U. Santa Maria della Misericordia, Udine, <sup>3</sup>Diabetes and Metabolism Unit, O.C. di Spilimbergo, Udine, <sup>4</sup>Diabetes Unit, Department of Medicine, INRCA – IRCCS, Ancona, <sup>5</sup>Diabetes Unit, ASL NA 2 NORD, Napoli, <sup>6</sup>Department of Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro, <sup>7</sup>Diabetes and Metabolism Unit, ASL TO5, Chieri, Italy.

**Background and aims:** The prevalence of diabetes in people over 65 years approaches 20%, while at least 50% of all patients with diabetes are older than 65 years. Clinicians who manage older people with diabetes require special skills to provide high-quality care. In the context of a continuous quality improvement initiative promoted in Italy by Associazione Medici Diabetologi (AMD Annals initiative), we evaluated the quality of care provided by diabetes clinics to young old (i.e. 65–74 years) and old patients (i.e. >75 years) as compared to younger ones.

**Materials and methods:** Overall, 251 diabetes clinics (one third of all clinics in Italy), all using electronic medical record systems, extracted data relative to the year 2009. The proportion of patients with at least one value registered during the year (process measures), the percentage of patients reaching specific favourable or unfavourable targets (intermediate outcome measures), and rates of use of drugs were evaluated. In addition, a quality of care summary score (Q score) was calculated. The Q score, ranging between 0 and 40, is based on process and outcome indicators (HbA<sub>1c</sub>, blood pressure, LDL-cholesterol, microalbuminuria) and is closely related to long-term outcomes in diabetic patients.

**Results:** Overall, 414814 patients were evaluated, of whom 34.9% were aged 65–74 years and 25.2% ≥75 years (mean age 70.0±2.8 and 80.3±3.9, respectively vs. 55.8±7.8). As compared to younger patients, young old and old individuals were less often males (54.8 and 45.2 % vs. 57.9%), had lower BMI (29.5±5.0 and 28.3±4.6 vs. 30.0±5.4 Kg/m<sup>2</sup>), longer diabetes duration (11.3±9.3 and 14.1±10.9 vs. 9.3±8.5 years), and were less likely to smoke (13.8% and 7.2% vs. 20.3%). Table 1 shows quality of care indicators.

	Indicator	<65	65-74	≥75
Process	HbA <sub>1c</sub>	92.5	93.3	91.2
	Blood pressure	80.0	80.3	74.8
	Lipid profile	75.1	75.2	68.1
Favourable outcome	Microalbuminuria	42.8	42.9	37.0
	HbA <sub>1c</sub> ≤7%	43.4	45.0	42.5
	BP ≤130/80 mmHg	17.5	13.5	13.7
	LDL-C <100 mg/dl	38.2	44.4	43.9
Unfavourable outcome	HbA <sub>1c</sub> ≥9%	16.5	10.8	10.9
	BP ≥ 140/90 mmHg	51.1	60.3	62.1
	LDL-C ≥130 mg/dl	29.6	23.5	23.5
Treatment	Oral agents:			
	Metformin	62.0	56.0	42.1
	Sulfonylureas	31.8	36.6	36.2
	Insulin	11.4	15.6	23.4
	≥2 antihypertensive agents	14.8	23.6	25.1
	Lipid-lowering agents	39.7	45.8	37.4
Global	Q SCORE <15	8.3	7.3	7.7
	Q SCORE >25	37.2	37.6	33.1

**Conclusion:** Care provided by diabetes clinics to elderly patients seems to be different compared to younger individuals. Elderly patients are less frequently monitored for blood pressure, lipid profile and microalbuminuria, but show slightly better intermediate outcomes and are more often treated with sulfonylureas and insulin. Despite a lower Q score, intensity of treatment does not seem to be affected by patient age.

## 1021

### An innovative community health worker training program: addressing the diabetes pandemic through expansion of the diabetes health care team

K.M. Collieran<sup>1</sup>, E. Harding<sup>1</sup>, A. Zurawski<sup>1</sup>, D. Somm<sup>1</sup>, B. Kipp<sup>2</sup>

<sup>1</sup>Internal Medicine, University of New Mexico HSC, Albuquerque,

<sup>2</sup>President, Blackfeet Community College, Blackfeet Tribe, USA.

**Background and aims:** Diabetes is rapidly becoming a pandemic. Health care systems are ill-equipped to meet the demands of the impending global diabetes crisis. Rapid expansion of the diabetes work force and mobilization of diabetes care teams will be essential to prevent devastating morbidity, mortality and financial disaster. Lay health workers serve as health care extenders and patient advocates across the world. They are effective in their mission due to their dedication, low cost, cultural, linguistic, and community understanding of the patients they advocate for. We hypothesize that community health workers (CHWs) can be trained using a distance learning model to become diabetes health extenders to increase the diabetes work force and expand the diabetes care team in a culturally appropriate, low cost, and effective manner. **Materials and methods:** We devised a multi-modality diabetes training program for CHWs that included a three day hands on intensive didactic, clinical skills and communications training, along with asynchronous video modules. Subjects then participated in a 6-month weekly distance case based and didactic learning program, using internet and video conferencing. Subjects completed evaluations at baseline and following the 6-month program. Surveys used included the Michigan Diabetes Attitude Survey (DAS-3), a modified version of the Michigan Diabetes Knowledge Test (mDKT), and a Diabetes Confidence Survey (DCS) for both clinical and nonclinical skills for diabetes. Subjects also completed 1:1 pre and post participation evaluations to assess mastery of specific diabetes related clinical and knowledge skills. Finally supervisors were asked to evaluate the effect the training had on their organisations and diabetes programs. Data were analysed using paired students t tests. Significance (p) and effect size were determined (d).

**Results:** Fifty CHWs completed the program including 4 men and 46 women; 30 Native Americans, 12 Hispanics, and 7 Whites. Subjects improved in all five domains of the DAS-3, but statistical significant improvements were only seen in the Seriousness and Patient Autonomy scales (p<0.01 and <0.05, d=0.41 and 0.38 respectively). Participation in the program resulted in a significant improvement in the mDKT mean percent correct (pre 58.2% to post 68.4 % (p < 0.0001, d = 0.76). Significant improvements in confidence in clinical and non clinical skills were seen from pre to post testing (p <0.0001, d>0.9).

All domains of clinical skills testing improved significantly including blood pressure, blood sugar, and BMI measurement and interpretation, depression screening, diabetic foot exam, and medication counseling. Finally, supervisors reported significant improvements in CHW's skills (composite score of 18 parameters) and integration into the diabetes care team as a result of participation in the program (p<0.001, d=1.7, and p<0.001 d=1.78, respectively).

**Conclusion:** We have demonstrated that our innovative training program led to significant improvement in CHW attitudes, knowledge, clinical skills and confidence in their abilities in these areas. Additionally, their supervisors recognized the value of the training and increased CHW responsibility and integration in diabetes care teams. Specialized training of CHWs in diabetes is a potential mechanism to help address the global diabetes epidemic.

### Quality management in care groups and outpatient clinics in the Netherlands

M.J.E. Campmans-Kuijpers<sup>1</sup>, L.C. Lemmens<sup>2</sup>, C.A. Baan<sup>3</sup>, K.J. Gorter<sup>1</sup>,

J. Groothuis<sup>3</sup>, K.H. van Vuure<sup>3</sup>, G.E.H. Rutten<sup>1</sup>;

<sup>1</sup>Julius Center, University Medical Center Utrecht, <sup>2</sup>National Institute for Public Health and the Environment, Bilthoven, <sup>3</sup>Knowledge Centre for Chain Care, Zwolle, Netherlands.

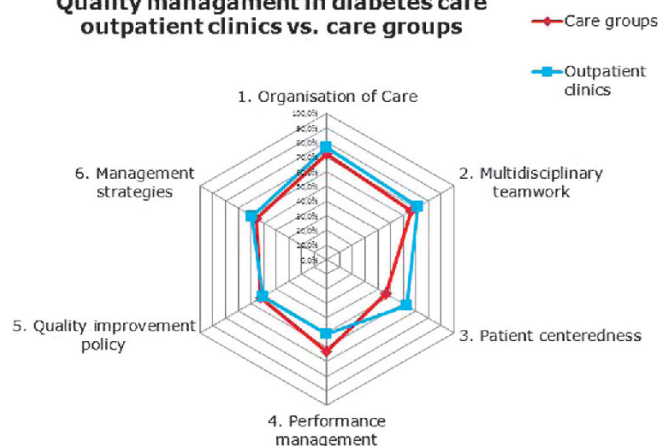

**Background and aims:** In the Netherlands, standard diabetes care is provided either in diabetes care groups (n=97) or outpatient clinics (n=104) using a diabetes care program. The organisation or care groups varies and is still under development. Quality of care indicators have been addressed enormously during the last years. However, it is essential to understand the comprehensive elements needed for good quality management and assurance of care at organisational level too. The aim of this study is to investigate in what way the above mentioned organisations organise quality management. In January-March 2012 we measured the actual level of quality management of care for T2DM patients in care groups and outpatient clinics nationwide.

**Materials and methods:** Based on current literature online questionnaires for quality managers were developed for measuring the level of quality management in outpatient clinics and in care groups separately. Results of questionnaires were plotted in a radar diagram consisting of six domains of quality management. Scores in the domains (0-100%) and sub domains were compared with the mean score in care groups or outpatient clinics.

**Results:** Totally 203 quality managers were invited to fill out the online questionnaire (97 care groups, 104 outpatient clinics). Responders of 60 care groups (response rate 61.9 %) showed a mean score of 59.4% (median 60.3, range 39-77%). Responders on behalf of 52 outpatient clinics (50%) had a mean score of 61.9% (median 59.7%, range 27-89%). The six domains gave the following mean scores for care groups and outpatient clinics respectively: organisation of care 71.9%, 76.8%; multidisciplinary teamwork 66.6%, 71.5%; patient centeredness 46.3%, 62.5%; performance management 64.0%, 50.9%; quality improvement policy 52.7%, 50.9% and management strategies 56.0%, 59.0%. Results in sub domains revealed that outpatient clinics have a low score on the patients' right to scrutinize of their medical file (28.0%) and patient involvement (26.8%), and care groups hardly focus on patient involvement (17.2%) and patient safety (15.3%).

**Conclusion:** This nationwide overview of diabetes quality management policy shows reveals that groups focus more on performance management and less on patient centeredness, whereas outpatient clinics focus less on performance management and more on patient centeredness.

### Quality management in diabetes care outpatient clinics vs. care groups

### The novel use of commonly captured data to assess a district's diabetes service that evaluates both primary and secondary care

E.C. Russell-Jones<sup>1</sup>, A. Gough<sup>2</sup>, I.N. Scobie<sup>2</sup>;

<sup>1</sup>Medicine, GKT Medical School, King's College London, <sup>2</sup>Diabetes and Endocrinology, Medway Maritime Hospital, Medway, UK.

**Aims:** There is a need to assess performance of diabetes care that encompasses both primary and secondary care in the UK. None of the quoted schemes do this. However data are routinely collected and freely available that would allow a new index to be created that looks at both primary and secondary care within a district or region. The routinely collected data include: 1. Primary care QOF (Quality outcomes framework) information/data for diabetes (a marker of primary care performance). 2. Referral rates for first appointment for specialist secondary care review, a marker of how often secondary care help is being sought (Dr Foster/ HES Hospital Episode Statistics). 3. Emergency admission rates for diabetes (markers of how often emergency treatment is needed from primary care). (Dr Foster/HES).

**Methods:** To investigate this new index, a district diabetes service (Medway PCT (300,000 population) that encompasses both rural and urban communities) was studied. The most illustrative measures from QOF were total points (sum of all diabetes indicators) and DM23 attainment of HbA1c <7% combined with its exemption reporting rate (number of patients excluded by each practice from analysis). Performance was compared to the other 8 PCTs within the South East Coast SHA. Dr Foster data were used that included SAR (Standardised admission rate) for first or new OPD referral to specialist diabetes services and SAR for emergency diabetes admissions to hospital.

**Results:** NHS Medway has the highest prevalence of Diabetes at 6.1% of all the 8 PCTs in the SHA. Medway has a lower achievement of diabetes QOF points (96.1%) relative to other PCTs. Medway has the lowest achievement of an HbA1c level <7% (54.3%) across all the PCTs within the SHA. Exemption reporting was also 3<sup>rd</sup> highest within the SHA. SAR for first/new diabetes OPD appointment to the hospital was very low at 281, (predicted 576) 48% of expected. The emergency admission rate was high at 225 (predicted 168), producing an emergency admission SAR of 133% expected.

Title	Medway	SHA Average	Number	Expected	SAR Standardised admission rate
Prevalence of Diabetes %	6.1	5.1			
Total QOF DM points	96.2	96.6			
DM23 % attaining HbA1c <7%	54.3	55.8			
Exemption % DM 23	14.2	13.7			
First/new OPD referral to Hospital			281	576	48%
Emergency Admission to Hospital			225	168	133%

This new index shows that Medway district has a high prevalence of diabetes, a relatively low attainment of primary care QOF diabetes points and high exception reporting rate. The referral rate for new diabetes referrals to specialist OPD is low in comparison to the national average, and there is a considerably higher emergency admission rate. Thus primary care diabetes needs more resources and support to raise performance and there should be a lower threshold for OPD referral of complex patients to specialist hospital clinics to prevent/lower emergency admissions.

**Conclusion:** It is possible to combine routinely available data to produce an assessment of diabetes care that transcends primary and secondary care (applicable anywhere in UK) that gives a true reflection of a district's performance which will be useful to plan future health provision.

## 1024

### Risk factors for dropping out of a disease management programme (DMP). Results from the DMP diabetes mellitus type 2 in the North Rhine region, Germany

L. Altenhofen, B. Hagen, J. Kretschmann, A. Weber;  
Central Research Institute for Ambulatory Health Care in Germany, Cologne, Germany.

**Background and aims:** Published evidence with regard to a possible selection bias when entering a DMP for the indication of diabetes mellitus type 2 is inconsistent. So far no systematic analyses exist which examine the differences between patients who stay in or who drop out of the programme. For the North Rhine region, Germany, the group of drop out patients is described quantitatively. A statistical model of the DMP drop out risk is developed.

**Materials and methods:** Until the end of 2010 423 534 patients took part in the DMP. In contrast until the end of 2009 33 321 former patients did drop out of the programme. According to administrative data (limited availability) 5 699 of these 33 321 patients died. So a total of 27 622 drop out patients was left for analyses. As a first step data were analysed by descriptive statistics. As a second step the risk for dropping out of the DMP was calculated via logistic regression analysis (odds ratios and 95 percent confidence intervals are given).

**Results:** With regard to the last documented data of both populations in 2009 by comparison to patients who continued participation patients who left the DMP were on average one year older ( $67.8 \pm 14.2$  vs.  $66.5 \pm 11.6$  years) and did suffer longer from diabetes ( $10.0 \pm 7.8$  vs.  $8.4 \pm 7.0$  yrs.). Average hba1c percentage was slightly increased among patients who left the DMP ( $7.2 \pm 1.5$  vs.  $7.0 \pm 1.2$ ). In addition frequencies of missed patients' education were higher among patients who left the DMP (15.4 vs. 12.3 %). In the multivariate model older age (76 yrs. or more vs. 65 yrs. or less, OR 1.71, CI 1.62-1.81), incidence of difficult comorbidities (blindness, dialysis, amputation, OR 1.73, CI 1.49-2.01), hba1c percentage of 8.5 or more (OR 1.83, CI 1.72-1.94) as well as inpatient diabetic care (OR 1.58, CI 1.26-1.99) were the most significant risks for dropping out of the DMP. Large correlations were observed too with missed patients' education (OR 1.35, CI 1.29-1.41) and missed eye examination (OR 1.96, CI 1.86-2.05).

**Conclusion:** Patients who drop out of the DMP are older, suffer longer from diabetes, require more often inpatient care and suffer more often from difficult comorbidities. In addition the larger risks of missed patients' education and eye examination can be a sign of a lower level of therapeutic adherence among these patients. Actually patients who prematurely leave the DMP are an important target group of a structured care programme. Therefore thoroughly organised additional studies of the DMP are urgently needed to ex-

amine the different individual reasons for dropping out of the programme. These reasons should be verified too in other German regions where DMPs are implemented.

## 1025

### Cost of diabetes care and its association with good glycaemic control: a hospital based study

A. Afroz<sup>1</sup>, M. Shahjahan<sup>1</sup>, M. Hafez<sup>1</sup>, L. Ali<sup>2</sup>;

<sup>1</sup>Department of Biostatistics, Bangladesh Institute of Health Sciences,

<sup>2</sup>Department of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh.

**Background and aims:** Diabetes is creating a major socio-economic burden on individual, societal and state levels, and cost-effectiveness of interventions against this disorder is a high priority particularly in developing countries. Primary evidence on these issues are scarce even in developed world and these are almost absent in the developing countries. The present study was undertaken to assess the cost-effectiveness of good glycemic control in a Bangladeshi type 2 dietetic population.

**Materials and methods:** A cross-sectional study was conducted among 496 registered patients (aged  $\geq 30$  years) of Out-Patient Department of the central hospital of Diabetic Association with more than 1 year duration of diabetes. Effectiveness of treatment was judged by good glycemic control with FSG < 6.1 mmol/L as the cut-off value. All treatment related records of the last 1 year were collected from patients' guide books. The degree and extent of complications like cardiopathy, retinopathy, nephropathy and vasculopathy were recorded and direct, indirect & incremental cost of the management of diabetes and complications were calculated from consumers' point of view. Direct cost included consultation fees, drugs, laboratory investigation and other medical services. Indirect cost included opportunity cost of participants and attendance calculated by human capital approach.

**Results:** Among 496 patients 46% were males and 54% were females with mean  $\pm$  SD duration of diabetes  $8.8 \pm 6.8$  years. Among them 31% have good glycemic control. The average annual cost of care was US\$ 313 (direct US\$ 283 & indirect US\$ 31) per patient. Drugs accounted for the largest share of direct cost US\$ 193 (67%), followed by laboratory investigations US\$ 27 (13%) and consultation fees US\$ 23 (12%). Average annual cost of participants with good glycemic control was US\$ 303 and with poor glycemic control it was US\$ 318; the difference was statistically significant ( $p < .05$ ). Participants with the poor glycemic control were significantly more likely to have complications [( $p = .049$ ) OR 1.5 (95% CI 1.0–2.3)] and co-morbidities [( $p = .02$ ) OR 1.5 (95% CI 1.0–2.2)] than participants with good glycemic control. Participants with both cardiopathy-retinopathy had 2.3 times, both cardiopathy-nephropathy had 1.8 times and both nephropathy-retinopathy have 3.4 times higher cost of care compared to participants without complications. The annual medical costs of good glycemic control participants increased with increase in the number of complications/co-morbidities. Without complications/co-morbidities spent US\$ 271 but the cost increased to US\$ 294 with one/two and US\$ 378 with more than two. The annual cost of poor glycemic participants increased rapidly with complications/co-morbidities: US\$ 276, US\$ 318 and US\$ 419 for without complications/co-morbidities, one/two and more than two respectively. Multiple regression analysis showed that number of complications/co-morbidities ( $p = 0.01$ ) and duration of diabetes were significant ( $p = 0.01$ ) explanatory variables of annual cost of care ( $R^2 = 0.16$ ;  $F = 23.9$ ,  $P < 0.001$ ).

**Conclusion:** The average annual cost of diabetes care per patient in Bangladesh is US\$ 313 and with an estimated 9.5 million diabetic patients, the total annual burden will be US \$ 2973.5 million. Good glycemic control can lead to substantial cost saving through prevention and control of complications.

### 1026

#### Efficacy and safety of insulin pump treatment in young adult patients with type 1 diabetes mellitus

T. Klupa, B. Matejko, K. Cyganek, M. Grzanka, E. Kozek, M.T. Malecki; Department of metabolic Diseases, Jagiellonian University, Krakow, Poland.

**Background and aims:** Continuous subcutaneous insulin infusion (CSII) via personal insulin pumps is a valuable therapeutic tool in T1DM patients. However, it is not clear whether this treatment is equally effective in different patient subgroups. Adherence to recommended CSII-related behaviors may especially be of concern in young adults with intensive, variable daily activities (students, young professionals). The aim of this observational study was to estimate treatment outcomes in young adult patients with T1DM and compare them with older individuals.

**Materials and methods:** Overall 140 adults with T1DM on CSII were examined; they were divided into two subgroups: 77 patients younger than 26 years of age (range 18–26 years, mean 20.6 years) and 63 older subjects (range 26.5–75.5 years, mean 39.0). The younger subgroup was characterized by shorter diabetes duration (10.0 years vs. 17.7 years,  $p < 0.00001$ ). The groups did not differ with respect to BMI (22.8 kg/m<sup>2</sup> in young T1DM subjects vs. 23.7 kg/m<sup>2</sup> in older patients,  $p = 0.07$ ). Individuals with shorter than a 3-month history of CSII treatment were excluded from the analysis. We compared glycemic control in both groups of T1DM subjects and analyzed treatment attitudes to identify potentially modifiable behaviors influencing the treatment efficacy. The available insulin pump and blood glucose meter downloads as well as HbA1c levels were reviewed. We analyzed records of insulin pumps from the last 4–6 weeks, while for glucometers the whole memory content (200–300 records depending on glucometer type) was included.

**Results:** Younger individuals were characterized by significantly worse treatment outcomes as compared to the older population: mean HbA1c levels were  $7.6 \pm 1.3\%$  and  $6.9 \pm 1.3\%$  ( $p = 0.00001$ ), while mean glucose levels based on glucometer downloads were  $161 \pm 33.6$  mg/dL and  $136 \pm 21.8$  mg/dL ( $p = 0.00001$ ), respectively. Of interest, there were no differences in glucose variability (SD/x mean  $\times 100\%$ ) between the two groups ( $46.7 \pm 9.1\%$  vs.  $44.3 \pm 8.2\%$ , for younger and older individuals, respectively,  $p = 0.1498$ ). The number of hypoglycemic episodes (defined as glycemia  $< 55$  mg/dL) for 100 measurements was higher in older vs. younger patients ( $6.2 \pm 4.9$  vs.  $4.5 \pm 4.0$ ,  $p = 0.0352$ ).

**Conclusion:** The efficacy of CSII treatment observed in young T1DM adults was worse as compared to older patients. Possible reasons include lower SMBG frequency and less frequent use of advanced insulin pump options. The higher number of hypoglycemia/100 measurements in older individuals may be due to stricter glycemic control or to a higher number of SMBG measurements in this group.

### 1027

#### Identifying characteristics of insulin pump use that predict good diabetes control in patients with type 1 diabetes

S. Sivasubramaniyam<sup>1</sup>, L. Green<sup>1</sup>, S.A. Amiel<sup>1</sup>, P. Choudhary<sup>1</sup>;

<sup>1</sup>Diabetes Research Team, King's College Hospital, London, UK.

**Background and aims:** Continuous subcutaneous insulin infusion (CSII) therapy is an increasingly common treatment option for type 1 diabetes. However, a proportion of patients fail to achieve glycaemic targets despite CSII. We examined differences in pump set-up and usage characteristics between patients with target and sub-optimal glycaemic control as well as patients with low and high rates of hypoglycaemia.

**Methods:** All adult patients with type 1 diabetes treated with CSII at a single hospital clinic were considered ( $n = 454$ ). Exclusion criteria were CSII treatment  $< 6$  months, pregnancy, haemoglobinopathy, continuous sensor use and lack of pump download in past year. 198 patients meeting these criteria were categorised into those with target [HbA1c  $< 7.5\%$  ( $n = 52$ )] and sub-optimal [HbA1c  $\geq 7.5\%$  ( $n = 146$ )] glycaemic control. Patients were also divided into those with high [ $\geq 3$  episodes/week ( $n = 76$ )] and low [ $< 3$  episodes/week ( $n = 105$ )] rates of hypoglycaemia [defined as capillary glucose  $< 4$  mmol/L]. Capillary glucose readings, pump set up and usage characteristics were obtained from the last available pump download with concurrent HbA1c obtained within a month.

**Results:** There were no significant differences in baseline characteristics [age, gender, ethnicity, duration of CSII, days of download data] between the target

and sub-optimal glycaemic control group except in mean weight [72.3(±11.6) vs 78.1(±14.3) kg  $p=0.018$ ] and hence BMI [25.5(±3.6) vs 27.2(±4.5) kg/m<sup>2</sup>  $p=0.03$ ]. Similarly, there were no significant differences in baseline characteristics between those with low and high rates of hypoglycaemia. Patients with target glycaemic control used more basal rates [5.57(±2.6) vs. 4.84(±1.8);  $p=0.029$ ] and boluses per day [6.1(±2.1) vs. 5.2(±2.1);  $p=0.004$ ] and had lower insulin to carbohydrate ratios [1.17(±2.8) vs. 1.36(±2.5) u/10g CHO;  $p=0.02$ ]; but there were no differences in total insulin/day, total daily dose/kg or proportion basal insulin than those with sub-optimal control. Target control group had more frequent hypoglycaemia [4.1(±3.6) vs. 2.7(±2.8) episodes/week;  $p=0.009$ ]. Patients with high rates of hypoglycaemia tested blood glucose more often [6.4(±2.1) vs. 3.94(±2.0)/day;  $p<0.0001$ ], gave more boluses [5.75(±1.8) vs. 5.15(±2.1);  $p=0.018$ ] and used the bolus calculator more [4.89(±2.1) vs. 4.1(±2.4);  $p=0.009$ ] but also overrode the bolus calculator more frequently [16.7(±19.5) vs. 13.7(±20.1)%;  $p=0.02$ ]. Post-hoc analysis showed that these differences were irrespective of glycemic control grouping. Patients in the low hypo rate group had significantly higher average blood glucose [10.7(±3.0) vs. 8.8(±1.4) mmol/L;  $p<0.0001$ ] and HbA1c [8.3(±1.1) vs. 7.8(±1.1)%  $p=0.003$ ].

**Conclusion:** Target glucose control on CSII was associated with higher number of basal rates and a greater number of boluses per day suggesting greater engagement with the pump, and more pro-active management of glucose control. However, target HbA1c was also associated with greater biochemical hypoglycaemia. Irrespective of glucose control, increased hypoglycaemia was associated with more frequent capillary testing, suggesting increased vigilance. Further studies exploring pump usage characteristics that results in optimal glycaemic control without problematic hypoglycaemia are merited.

## 1028

### Trends in the treatment of type 1 diabetes with CSII vs MDI: a Canadian retrospective observational study

J. Alfonso Ross Terres, A.D. Jabbour, M.A. Freeman;  
Medical, GSK, Mississauga, Canada.

**Background and aims:** Patients with type 1 diabetes mellitus (T1DM) are treated with insulin via continuous subcutaneous insulin infusion (CSII) or multiple daily injections (MDI). CSII is becoming a more common modality of insulin delivery, as improvements in glycemic control, reductions in glucose fluctuations and reduced rates of severe hypoglycaemia are reported in published literature. The purpose of this observational study was to follow a Canadian cohort of T1DM patients over time to better understand the use of CSII and MDI and the rate of switching between the two insulin modalities.

**Materials and methods:** A national pharmacy-based database (IMS Brogan) was utilized to identify a cohort of T1DM patients, followed from 2008 to 2010. Patients with a prescription history of oral antidiabetic drugs, long-acting/premix insulin monotherapy, inconsistent reporting of data in the last 58 months or fewer than 6 prescriptions were excluded from the cohort. Those without data over the full 2-year study period were excluded from the analysis. Patients were categorized by treatment modality based on insulin prescriptions. CSII users were defined as patients on rapid analog insulin only and MDI users were defined as those on a combination of rapid and long acting insulin. Those not categorized as CSII or MDI users were classified as Other. The cohort was followed over a 2-year period to assess switching between treatment modalities.

**Results:** A cohort of 47,396 T1DM patients was identified in 2008; 39,800 (84%) were classified as MDI patients, 5,858 (12%) as CSII and 1,738 (4%) as Other. After 2 years of follow-up, 36,550 (92%) of the MDI patients continued on MDI modality, 2,567 (6%) switched to CSII, 494 (1%) switched to Other and <1% returned to MDI after switching over the 2 years. Of the 5,858 patients in the CSII group, 4,819 (82%) continued on CSII, 844 (14%) switched to MDI, 58 (1%) switched to Other and 137 (2%) returned to CSII after switching over the 2 years. Of the 1,738 patients in the Other group, 1,056 (61%) continued on Other, 572 (33%) switched to MDI, 91 (5%) switched to CSII and 19 (1%) returned to Other after switching over the 2 years. Of the patients switching treatment modalities in 2009, the overall most common change was MDI to CSII, representing 47% of switches; this increases to 55% of switches in 2010. Although the majority of patients included in this study were ≥ 40 years old (64%), switching from MDI to CSII was more common in patients aged <20 years (16%) vs. ≥20 years (5%).

**Conclusion:** Over 2 years of follow-up, the majority of the T1DM cohort used MDI treatment modality and did not switch. A trend towards the adoption of CSII was observed. Switching from MDI to CSII was most common among younger patients. The limitations of the analysis were the short study

period and inability to adjudicate the CSII and MDI categorization. Further research is necessary to understand the potential long term benefits of CSII in comparison with MDI.

## 1029

### Clinical assessment of DIAAdvisor device shows high accuracy in glucose prediction at 20-min horizon and a coherence of most advices on therapy in patients with type 1 diabetes

A. Farret<sup>1</sup>, E.M. Renard<sup>1</sup>, J. Place<sup>2</sup>, M. Mindlova<sup>3</sup>, E. Vavrova<sup>3</sup>, F. Saudek<sup>3</sup>, M. Vedovato<sup>4</sup>, A. Maran<sup>4</sup>, A. Avogaro<sup>4</sup>, DIAAdvisor consortium;

<sup>1</sup>Department of Endocrinology, Diabetes, Nutrition, Montpellier University Hospital, <sup>2</sup>Department of Endocrinology, Diabetes, Nutrition, University of Montpellier I, France, <sup>3</sup>IKEM, Prague, Czech Republic, <sup>4</sup>University of Padova, Italy.

**Background and aims:** The DIAAdvisor device has been designed in view of predicting blood glucose at a close time horizon and delivering advices on correction measures in order to maintain blood glucose in a near-normal target range in patients with type 1 diabetes (T1D) using a basal-bolus insulin regimen by multiple daily insulin injections or insulin pumps. Inputs include patient information on carbohydrate intakes, insulin dose administration and continuous glucose monitoring (CGM) data. In DIAAdvisor-1 study, we investigated the accuracy of blood glucose prediction at a 20-min horizon and the coherence of treatment advices in various life conditions.

**Materials and methods:** Twenty-nine T1D patients volunteered to assess DIAAdvisor device in three Clinical Research Centres at Montpellier (MPL), Prague (IKEM) and Padova (PAD) for 2 days at rest. Among them, 7 were also submitted to an exercise bout (MPL), 9 to induced hyper- and hypoglycaemic conditions (IKEM) and 8 to a large meal challenge (PAD). The device includes an Ultra Mobile (UM) PC with a patient interface and a USB connection to a CGM DexCom Seven-Plus receiver. Algorithms for glucose prediction and treatment advice are uploaded on the UMPC. Predictions and advices were blinded to the patient but wirelessly transmitted to a nearby clinician monitoring station. The primary endpoints and success criteria were: (i) accuracy of blood glucose prediction at a 20-min horizon assessed by using Clarke error grid analysis of paired predicted glucose values and YSI glucose measurements with > 80% of paired points in A+B zones and <5% in E zone (>75 and <10%, respectively, during challenges) and, (ii) advices given by the device on glucose and insulin corrections with > 80% coherence with clinician's advices.

**Results:** For 48 hours at rest, the accuracy of glucose prediction at 20 min was validated as shown by 89–100% of paired points in A+B zones and 0% in E zone in 28 out of 29 patients. One single case showed 13% of paired points in E zone. Success criteria for prediction were met during the various challenges in all patients except one who showed only 73% of paired points in A+B zones during a large meal test. The coherence of advices at rest reached 96.5, 80.8 and 88.6% with 85.7, 88.0 and 94.5 % full coherence, in MPL (n=11), IKEM (n=9) and PAD (n=9), respectively. During the challenges, the coherence of advices was 87.6, 91.3 and 91.4% with 82.0, 89.9 and 85.4% full coherence, in MPL, IKEM and PAD, respectively.

**Conclusion:** This pilot study shows that the DIAAdvisor device is able to provide successful prediction of blood glucose at a 20-min horizon and coherent advices for treatment correction in T1D patients at rest and during challenging conditions in a standardized hospital environment. Ongoing investigations will assess the outcomes of prediction and advices on glucose control when provided online to patients.

## 1030

### Fluorescence-based implantable glucose sensor with smartphone interface

T.K. Whitehurst, A.E. Colvin, A.D. DeHennis, J.C. Makous, M. Mortellaro, S. Rajaraman, J. Schaefer, D. Smith, S. Tankiewicz, O. Tymchyshyn, S. Walters, X. Wang;  
Sensors for Medicine and Science, Inc., Germantown, USA.

**Background and aims:** A fluorescence-based implantable glucose sensor has been developed. The small cylindrical sensor, which is approximately 3 mm in diameter and 14 mm long, has been designed to be inserted subcutaneously. A portion of the outer shell of the sensor includes a polymer hydrogel containing a proprietary indicator molecule that becomes fluorescent when it

binds glucose. The sensor includes a miniature fluorometer, with a tiny LED for excitation and multiple photodiodes for detection of the fluoresced signal. It also includes a highly accurate temperature sensor for compensation of the detected fluorescence. The glucose sensor has been designed to remain inserted for at least six months. The sensor is RF-powered, and an external body-worn reader is required to provide power to the sensor via a wireless inductive link. The reader also communicates with the sensor via a digital wireless inductive link to send commands to the sensor and to receive data from the sensor. The reader processes the sensed data to determine the sensor glucose value as well as the rate of change, and it is capable of storing up to 6 months of data. The reader includes a beeper and a vibration motor that are used to alert the patient, for example, when glucose passes a threshold value. The reader also includes a Bluetooth Low Energy link for communication with a smartphone as well as a USB port for charging and data exchange. Apps for the two most common smartphone platforms have been developed. The smartphone operates essentially as a user interface device for the reader, displaying data and providing user input, but it is not used to process sensor data or store data long-term. The smartphone app may be used to view sensor glucose data displayed graphically. The smartphone app also allows the user to enter data on daily events, for example, meals, insulin bolus administration, and exercise. All information entered by a patient is immediately transmitted to the reader.

**Materials and methods:** Two reader prototypes have been developed in support of pilot clinical studies. One is a wristwatch reader, designed for use with a sensor inserted subcutaneously in the dorsal wrist. The other is an armband reader, designed for use with a sensor inserted subcutaneously in the upper arm. The readers have each been programmed to read the implanted glucose sensor every two minutes. In a pilot study, 18 subjects were inserted bilaterally with a sensor in each arm. Each subject received at least one sensor in the wrist, while 7 subjects received the second sensor in the contralateral upper arm. The sensors remained inserted for 24 to 28 days, and subjects came to the clinic every three to six days to have the sensors read for 8 hours. Blood samples were also taken every 15 minutes and processed using a YSI Blood Glucose Analyzer. A single blood glucose value from the beginning of each clinic day was used to calibrate each sensor for each session, and the sensor glucose values were calculated prospectively for the session.

**Results:** The combined MARD for the 7 sensors inserted in the upper arm was 14.3%, and the MARD for the 20 sensors inserted in the wrist was 15.2%, using a single blood glucose value daily for calibration and prospective calculation of the sensor glucose values.

**Conclusion:** Clinical data from a 28-day pilot study of an implantable fluorescence-based glucose sensor has demonstrated the feasibility of the sensor.

## 1031

### Skin autofluorescence is associated with microvascular complications in type 2 diabetes

M.M.A. Yuen<sup>1</sup>, W. Chow<sup>1</sup>, C.H.Y. Fong<sup>2</sup>, K.S.L. Lam<sup>2</sup>;

<sup>1</sup>Department of Medicine, Queen Mary Hospital, <sup>2</sup>Department of Medicine, University of Hong Kong, Hong Kong

**Background and aims:** Skin autofluorescence (AF) is a marker of advanced glycation endproduct (AGE) accumulation in the body. AGEs are molecules formed through the non-enzymatic reactions of reducing sugars with proteins, lipids and nucleic acids. They accumulate at a constant but slow rate in the normal body. With increased glucose availability in diabetes, their formation is accelerated, and their deleterious effects on proteins have been implicated in diabetic complications. Upon excitation at 370 nm, AGEs have an emission spectrum at 440 nm, which is quantifiable as skin AF. This cross-sectional study investigated the relationship between skin AF and microvascular complications in Chinese type 2 diabetic subjects.

**Material and methods:** Subjects were recruited from the diabetic complication assessment program of our hospital. Skin AF was measured over the volar surface of the forearms using the AGE Reader. Three measurements were taken over each forearm according to the manufacturer's instructions, and the skin AF, in arbitrary units (AU), was recorded as the average of the three measurements on each side. To adjust for the effect of skin pigmentation, which absorbs light and thus influences skin AF, the AGE Reader automatically compared skin reflectance measurements across the 300 to 420 nm range with those of a white Teflon block, which was assumed to have 100% reflectance. Anthropometric and biochemical data including body height and weight, blood pressure, fasting glucose and lipids and HbA1c were collected. Statistical analysis was performed with SPSS 19.0.

**Results:** Skin AF was measured in 322 Chinese type 2 diabetic subjects (192 male, 130 female, 63.9±11.0 years), of which 229 had one or more microvascular complication(s). The median DM duration was 10 years (interquartile range 6–15 years) and the mean HbA1c was 7.84±1.35%. Skin AF correlated positively with age ( $r=0.350$ ,  $p<0.001$ ), DM duration ( $r=0.256$ ,  $p<0.001$ ), serum creatinine ( $r=0.280$ ,  $p<0.001$ ) and smoking pack-years ( $r=0.287$ ,  $p=0.006$ ), but not HbA1c ( $p=0.306$ ). There was no gender difference in skin AF ( $p=0.73$ ). Subjects with any microvascular complication had higher skin AF than those without ( $2.41\pm0.48$  AU vs.  $2.17\pm0.37$  AU,  $p<0.001$ ). Skin AF was higher in subjects with retinopathy ( $2.41\pm0.46$  AU vs.  $2.26\pm0.45$  AU,  $p=0.006$ ), nephropathy ( $2.49\pm0.49$  AU vs.  $2.20\pm0.39$  AU,  $p<0.001$ ) and neuropathy ( $2.56\pm0.51$  AU vs.  $2.27\pm0.42$  AU,  $p<0.001$ ) compared to those without the respective complication. Skin AF was independently associated with nephropathy (OR for one AU increase in AF 2.65 [1.42–4.95];  $p=0.002$ ) and neuropathy (OR for one AU increase in AF 2.28 [1.15–4.54];  $p=0.019$ ) after adjusting for gender, age, smoking status and DM duration. The optimal skin AF cut-off value for having any microvascular complication, nephropathy and neuropathy were 2.263 AU (sensitivity 59.8%, specificity 63.6%), 2.263 AU (sensitivity 68.8%, specificity 62.0%) and 2.307 (sensitivity 70.1%, specificity 57.6%) respectively on ROC analysis.

**Conclusion:** Skin AF was associated with diabetic complications, in particular nephropathy and neuropathy, in Chinese type 2 diabetic subjects. The AGE Reader might serve as a simple and non-invasive method to evaluate the risk of diabetic microvascular complication.

Clinical Trial Registration Number: HKCTR-1153

## 1032

### Local heating at the insulin injection site by the use of the InsuPad is able to reduce post-prandial glucose excursion in daily life

N. Hermanns, B. Kulzer, T. Haak;

Research Institute of Diabetes Academy Mergentheim (FIDAM), Bad Mergentheim, Germany.

**Background and aims:** The insulin action profiles of subcutaneously injected short acting insulin analogues are still slow compared to physiologically released human insulin. Thus, postprandial glucose excursions cannot be avoided. InsuPad is a medical device designed to accelerate insulin delivery rate by applying local heat at the insulin injection site. Whenever an insulin injection is given, the skin surface temperature is heated up locally to 38.5 °C for 30 minutes. This pilot-study examines the impact of the InsuPad use on postprandial glucose excursions after breakfast and dinner in daily life conditions.

**Materials and methods:** Insulin resistant diabetic patients were instructed to use the InsuPad when injecting bolus insulin prior to breakfast and dinner for one month and to measure their blood glucose at least five times per day (pre- and post-breakfast, pre-lunch and pre- and post-dinner). In the other study phase patients were instructed to maintain the same blood glucose measurement schedule for one month, without using the InsuPad. The order of the study phases was randomized. All blood glucose data were transmitted to a central computer using the DIASEND System. A valid pre-post-prandial measurement time difference was 75–135 minutes. An ANOVA, controlling for order of study phase, patient and meal (breakfast vs. dinner) was used to analyze the effect of the InsuPad on postprandial glucose excursions. In this study 10 diabetic patients took part (30% type 1 diabetes, age:  $51.5\pm7.7$  yrs., diabetes duration:  $15.7\pm7.7$  yrs.; HbA1c:  $8.2\pm0.9\%$ ; bolus insulin dose:  $51.7\pm22.2$  insulin units per day; total insulin dose 0.92 insulin units per kg).

**Results:** Preprandial blood glucose levels were similar in the phase with ( $151.7\pm46.8$  mg/dl) and without the InsuPad ( $148.5\pm38.6$  mg/dl,  $p=.385$ ). Postprandial glucose decreased by  $0.05\pm59.1$  mg/dl, if InsuPad was used, whereas the postprandial glucose levels increased by  $11.3\pm56.3$  mg/dl if the InsuPad was not used ( $p=.011$ ). The number (283 vs. 257) and proportion of valid measurements (65.5% vs. 64.4%,  $p=.740$ ) in the phase with and without InsuPad were highly comparable. The time differences between pre- and post-prandial glucose measurements were very similar in both study phases ( $102.7\pm19.0$  vs.  $102.3\pm15.6$  minutes with and without InsuPad,  $p=.777$ ). The overall glycaemic control (mean total blood glucose values) was significantly lower when using the InsuPad compared to the no-use-phase ( $149.7\pm54.5$  mg/dl vs.  $158.7\pm57.7$  mg/dl;  $p=.016$ ). The percentage of hypoglycaemic ( $<60$  mg/dl) or hyperglycaemic values ( $>300$  mg/dl) was slightly decreased when using the InsuPad, but the difference was not statistically significant (% hypoglycaemic values 1.5% vs. 1.8%,  $p=.496$ ; % hyperglycaemic values 1.6% vs. 2.1%,  $p=.250$ ).

**Conclusion:** This pilot-study indicates that local heating of the insulin injection site in insulin resistant diabetic patients by using the InsuPad is able to

reduce post-prandial blood glucose excursions as well as mean daily glucose values significantly in daily life conditions. Safety parameters like the prevalence of hypoglycaemic and hyperglycaemic glucose measurements were not affected by the use of InsuPad.

### Phenomenology of free-living activities: quantifying what, when, and how much using new recognition methods based on triaxial accelerometry

C. Simon<sup>1,2</sup>, F. Gris<sup>3</sup>, J. Dugas<sup>1</sup>, T. Bastian<sup>1</sup>, A. Maire<sup>1</sup>, C. Villars<sup>1</sup>, M. Bourdin<sup>2</sup>, S. Blanc<sup>4</sup>, Y. Caritu<sup>5</sup>, E. Perrin<sup>5</sup>, P. Jallon<sup>3</sup>; <sup>1</sup>INSERM U1060, Lyon, <sup>2</sup>University of Lyon, <sup>3</sup>CEA-LETI, Grenoble, <sup>4</sup>IPHC, Strasbourg, <sup>5</sup>MOVEA, Grenoble, France.

**Background and aims:** Physical activity (PA) energy expenditure (EE) (PAEE) is a critical factor to consider for the prevention and treatment of diabetes and obesity. However, reference methods to measure PAEE are not easy to use routinely in free-living conditions. Motion sensors are being increasingly used as alternatives, but the posture and the nature of movements involved in different types of PA strongly affect the relationship between accelerometry data and PAEE. In particular, EE related to low intensity PA, the main activities in every-day life, is difficult to measure. Furthermore, in free-living conditions, the position of the device can hardly stay exactly the same at all times, which further affects PAEE estimates. This study aimed at testing the possibility to overcome these issues with an original algorithm using a new motion sensor coupling triaxial accelerometer and magnetometer.

**Materials and methods:** *Data acquisition:* 63 subjects aged 19 to 55 performed a set of standardized PA in the lab. Each subject was equipped with triaxial accelerometers (the new sensor and an Actigraph GT3X<sup>TM</sup>), and a combined accelerometer and heart-rate monitoring device (Actiheart<sup>TM</sup>). Indirect calorimetry (SERVOPRO 4100, Servomex, UK) provided simultaneous reference EE measurements. 29 subjects had a normal BMI, 17 were overweight and 17 obese. *Classification Algorithm:* Data from the new device were used to develop a classification algorithm. First, orientation of the sensor was estimated by advanced accelerometer signal processing. Then, a machine learning approach based on hidden Markov models was applied on the processed data to identify 6 types of PA. Several classifiers were tested, and their performance addressed with cross-validation procedures providing a good detection rate criterion (GDR = 1 if all identification events are correct). *PAEE predictions:* Accelerometer values were converted into counts on 2 axes and, for each group of PA, a predictive model of EE created using the indirect calorimetry data and classical regression methods. EE predictions for each identified PA were confronted with results from other devices, and from indirect-calorimetry, using MSE criteria. *Validation:* Validation in free-living conditions is still in progress. The recognition algorithm is tested by following 20 subjects performing different types of PA in a real-life setting over 3.5h. The quality of PAEE prediction models is tested with 120 subjects carrying all devices for 2 weeks. For 60 subjects, doubly labeled water will provide reference values of PAEE over these 2 weeks.

**Results:** *Classification Algorithm:* Of all classifiers tested, Naïve Bayes models identifying 6 groups of PA gave the best recognition results. The GDR for each activity was: 0.93 for lying, 0.93 for slouching, 0.69 for sitting, 0.87 for standing, 0.73 for walking, 0.63 for active walking; overall mean: 0.79. *PAEE Predictions:* The new approach predicted PAEE better than the other triaxial accelerometer, and better than, or as well as, the Actiheart<sup>TM</sup> built-in group algorithms.

**Conclusion:** Accelerometer coupled to magnetometer and performing recognition algorithms can overcome the main limitations of currently available tools in the measure of PAEE, and offer interesting tools for the follow-up of diabetic and/or obese patients.

### Structured SMBG intervention in patients with non insulin treated type 2 diabetes: the PRISMA study

F. Giorgino<sup>1</sup>, M. Scavini<sup>2</sup>, A. Ceriello<sup>3</sup>, D. Cucinotta<sup>4</sup>, A. Tiengo<sup>5</sup>, E. Bonizzoni<sup>6</sup>, R. Marino<sup>7</sup>, E. Bosi<sup>2</sup>;

<sup>1</sup>Endocrinology & Metabolic Diseases, University of Bari, Italy, <sup>2</sup>Internal Medicine, San Raffaele Scientific Institute, Milan, Italy, <sup>3</sup>CIBERDEM, Centro de Investigacion Biomedica en Red de Diabetes y Enfermedades Metabolicas Asociadas, Barcelona, Spain, <sup>4</sup>Internal Medicine, Policlinico Universitario Gaetano Martino, Messina, Italy, <sup>5</sup>Clinical and Experimental Medicine, University of Padua, Italy, <sup>6</sup>Medical Statistics and Biometry GA Maccacaro, University of Milan, Italy, <sup>7</sup>Diabetes Care, Roche Diagnostics, Monza, Italy.

**Background and aims:** Recent studies on structured testing algorithms for self monitoring of blood glucose (SMBG) in patients with non insulin treated (NIT) type 2 diabetes (T2D) have shown improvements in HbA1c and other diabetes outcomes. However, not all open questions have been answered so far. Aim of this study was to test whether structured SMBG (intensive structured monitoring, ISM) compared to discretionary, unstructured SMBG (active control, AC) improves HbA1c through the optimization of diabetes treatment in patients with NIT T2D.

**Materials and methods:** The PRISMA study is a 12-month, prospective, multicenter, open, parallel groups, randomized trial to evaluate the added value of an intensive, structured SMBG regimen in NIT T2D patients. All patients participated in a standard education program and were then randomized to either ISM (4 SMBG measurements 3 days/week, including fasting, pre-prandial, 2 h post-prandial and post-absorptive) or AC (50 measurements over 3 months). Patients randomized to ISM were trained to respond to SMBG values outside targets by lifestyle changes. During a 12-month follow-up, patients were assessed quarterly with diabetes medications prescribed based on HbA1c and SMBG to target fasting and/or post-prandial hyperglycemia and to avoid hypoglycemia in the ISM group or on HbA1c only in the AC group. Two primary endpoints were tested in the following hierarchical order: 1) the change in HbA1c levels from baseline to month 12; and 2) the proportion of participants reaching or maintaining the risk targets [Low Blood Glucose Index (LBGI)  $\leq 2.5$  together with High Blood Glucose Index (HBGI)  $\leq 5$ ] from baseline to month 12.

**Results:** We recruited 1,024 patients (age  $60 \pm 8.5$  yrs, 40% females, BMI  $30.5 \pm 5.4$ ) with NIT T2D (duration  $6.2 \pm 3.8$  yrs; baseline HbA1c  $7.4 \pm 0.7\%$ ) in 39 diabetes centers in Italy, randomized to ISM (n=501) or AC (n=523). HbA1c decreased significantly more in ISM than AC patients [difference in HbA1c at month 12:  $-0.12\%$  (95% CI  $-0.210$  to  $-0.024$ ),  $p=0.013$ , ITT population, n=949;  $-0.21\%$  ( $-0.331$  to  $-0.089$ ),  $p<0.001$ , PP population, n=553]. Patients reaching or maintaining the LBGI and HBGI risk targets in the ISM compared to the AC group were 84.2% vs 80.2% in ITT ( $p=0.122$ ), and 90.0% vs 82.5% in PP ( $p=0.038$ ) populations, respectively. Changes in prescription of diabetes medications occurred more often in the ISM than AC patients (54.3% vs 45.7%, respectively;  $p<0.001$ ). BMI decreased more in the ISM than in the AC group [difference in BMI at month 12:  $-0.16$  (95% CI  $-0.343$  to  $0.013$ ),  $p=0.07$ , ITT population;  $-0.29$  ( $-0.528$  to  $0.061$ ),  $p=0.014$ , PP population]. Two severe hypoglycemia occurred in one patient in the AC group.

**Conclusion:** In patients with NIT T2D and close-to-target HbA1c the use of structured SMBG to optimize medications and lifestyle changes improved HbA1c, without increasing BMI and with no risk of severe hypoglycemia.

### More frequent SMBG is associated with more frequent insulin boluses and lower HbA<sub>1c</sub>: baseline results from the ABACUS

R. Ziegler<sup>1</sup>, D.A. Cavan<sup>2</sup>, I. Cranston<sup>3</sup>, K. Barnard<sup>4</sup>, K. Barnard<sup>4</sup>, J. Ryder<sup>2</sup>, C. Vogel<sup>5</sup>, C.G. Parkin<sup>6</sup>, W. Koehler<sup>7</sup>, I. Vesper<sup>8</sup>, B. Petersen<sup>8</sup>, M. Schweitzer<sup>8</sup>, R.S. Wagner<sup>9</sup>;

<sup>1</sup>Diabetes Clinic for Children and Adolescents, Muenster, Germany, <sup>2</sup>Royal Bournemouth Hospital, UK, <sup>3</sup>Queen Alexandra Hospital, Portsmouth, UK, <sup>4</sup>University of Southampton, UK, <sup>5</sup>Internistisches Facharztzentrum, Langen, Germany, <sup>6</sup>CGParkin Communications, Inc., Boulder City, USA, <sup>7</sup>baseline statistics GmbH, Mannheim, Germany, <sup>8</sup>Roche Diagnostics GmbH, Mannheim, Germany, <sup>9</sup>Roche Diagnostics, Inc., Indianapolis, USA.

**Background and aims:** Self-monitoring of blood glucose (SMBG) is generally considered to be essential to the management of patients with type 1 (T1DM) and type 2 (T2DM) diabetes on multiple daily insulin injection (MDI) therapy. Although previous studies have shown an association between frequent SMBG and glycaemic control, we examined baseline data from a large clinical trial to determine if SMBG frequency actually correlated with better clinical outcomes.

**Materials and methods:** Baseline data were drawn from 219 T1DM (n=202) and T2DM (n=17) subjects enrolled in the Automated Bolus Advisor Control and Usability Study (ABACUS), a large, prospective, randomized, multi-national study of poorly controlled (HbA<sub>1c</sub> ≥ 7.5% / 58 mmol/l), MDI-treated patients. Subjects had a mean (SD) age 42.5 (14.1) years, BMI 26.4 (4.4), and HbA<sub>1c</sub> 8.85% (1.15). Demographic data, daily insulin bolus dose, HbA<sub>1c</sub> values, and self-reported SMBG frequency were correlated.

**Results:** Mean (SD) frequency of self-reported SMBG was 4.29 (1.51) tests/day. Frequency of SMBG was not significantly different between T1DM and T2DM subjects: 4.34 (1.51) vs. 3.76 (1.35) times per day; p = ns. SMBG frequency was similar in women and men: 4.25 (1.24) vs. 4.33 (1.70) times per day; p = ns. Mean (SD) frequency of SMBG was lower in subjects <30 years of age than older subjects: 3.83 (1.72) vs. 4.44 (1.41); p < 0.01. SMBG frequency did not correlate with education level, time from diagnosis to start of MDI, or length of time on MDI. Within the cohort, mean (SD) frequency of self-reported boluses was 3.54 (0.93) per day, with no differences according to type of diabetes, or gender. There was an association between frequency of SMBG and of boluses (r = 0.44) but not to total daily insulin bolus dose. There was a significant correlation with HbA<sub>1c</sub> (of r = -0.30), suggesting that more frequent SMBG is associated with lower HbA<sub>1c</sub>, independent of the type of diabetes.

**Conclusion:** These data suggest that patients treated with MDI therapy perform SMBG on average of 4-5 times daily independent of the type of diabetes, gender, or education level; however, younger patients tended to test less than older patients. We conclude that greater SMBG frequency was associated with more frequent insulin boluses and lower HbA<sub>1c</sub>. Frequent SMBG, when utilized to actively manage MDI therapy, may lead to more efficacious therapy and improved diabetes control. This will be evaluated in the ABACUS.

### Information management improves medical outcome and supports therapy decision in diabetes care: results from the multicenter observational VISION study

J. Weissmann<sup>1</sup>, A. Müller<sup>1</sup>, K. Pralle<sup>2</sup>, H.-J. Ruessmann<sup>3</sup>, B. Gregersen<sup>4</sup>, D. Messinger<sup>5</sup>, I. Amann-Zalan<sup>1</sup>;

<sup>1</sup>Roche Diagnostics Deutschland GmbH, Mannheim, Germany, <sup>2</sup>Diabeteszentrum am Sophie-Charlotte-Platz, Berlin, Germany, <sup>3</sup>Diabeteszentrum & Hausarztpraxis, Dinslaken Germany, <sup>4</sup>General Practice, Osted, Denmark, <sup>5</sup>Biometrics Department, IST GmbH, Mannheim, Germany.

**Background and aims:** Many people with diabetes do not achieve optimal glycaemic control despite executing self-monitoring of blood glucose (SMBG). The challenge of analyzing and interpreting the large amount of complex SMBG data has been suggested to impede a better performance. Computerized data management offers a method to facilitate this data process procedure. The prospective VISION study aimed to assess the effectiveness of information management (IM) with the Accu-Chek® Smart Pix system, a tool for uploading, analyzing and reporting blood glucose (BG) data, in usual outpatient diabetes care. Particularly the effects on process quality of diabetes

management as well as on patients' attitude to diabetes treatment were examined.

**Materials and methods:** 914 adults with type 1 and type 2 diabetes mellitus, respectively (T1DM, n=248 / T2DM, n=666 - thereof 88% insulin treated) with poor glycaemic control (HbA<sub>1c</sub> ≥ 7.5%) from 123 primary care centers in Germany and Denmark were enrolled and monitored for about 7 months. BG data were analyzed, put into graphs and tables and summed up in reports by the Accu-Chek Smart Pix system. To evaluate the everyday benefit of using these reports as basis for therapy decision and patient communication, HbA<sub>1c</sub> status and physician's opinion on the diabetes management process were assessed via a questionnaire before (baseline) and approx. 3 and 6 months after IM integration into the practice workflow. Particularly therapy adjustments and the role of the reports in this matter were documented and analyzed. According to the observational nature of the study, descriptive and explorative statistical methods were used to analyze the collected data after stratification by diabetes type (T1DM/T2DM). The degree of significance of the test results was set at α<0.05.

**Results:** Within approx. 3 and 6 months of IM usage, HbA<sub>1c</sub> significantly (p<0.0001) dropped on average by -0.61%/-0.64% in T1DM and by -0.88%/-0.93% in T2DM from baseline (T1DM: 8.48% / T2DM: 8.66%). This clinically relevant effect was accompanied by a distinct and significant (p<0.01) improvement in patient therapy understanding and compliance as well as by an optimization of the therapy decision process (e.g. due to time savings) and of the dialog with patients, as assessed by physicians. The current diabetes therapy of 56.9% T1DM and of 64.0% T2DM patients, was adjusted in the course of the study. Mostly, adaptations referred to the insulin therapy (up to 39.9%) and to lifestyle modifications (up to 20.6%). In the majority of these cases (T1DM: ≥65% / T2DM: ≥81%) physicians stated that their decision was triggered by information provided by the Accu-Chek Smart Pix reports used.

**Conclusion:** Integration of IM in usual outpatient diabetes care improved glycaemic status significantly and lasting - in T2DM even more than in T1DM. Also enhancement of process and outcome quality - concerning therapy decision, patients' communication and attitude to diabetes treatment - was stated by physicians. This suggests that computerized data management can provide valuable support to physicians in analyzing, interpreting and communicating complex SMBG data and patterns.

## 1037

### Evaluation of blood glucose monitoring system pattern alert messages in a home setting: patient reported insights

M. Grady<sup>1</sup>, D. Campbell<sup>1</sup>, K. MacLeod<sup>2</sup>, A. Srinivasan<sup>2</sup>, P. Raja<sup>2</sup>;

<sup>1</sup>LifeScan Scotland Ltd, Inverness, UK, <sup>2</sup>LifeScan Inc., Milpitas, USA.

**Background and aims:** Blood glucose monitoring systems (BGMSs) that contain on-meter pattern recognition software are intended to advise users via timely on screen messages about recent high and low glucose patterns. This enables users to gain insights into these events and to consider making changes in diabetes management or lifestyle. However, there are minimal data on user perception of these messages or user awareness of why specific patterns were generated.

**Materials and methods:** A clinical study was conducted to evaluate user perceptions of patterns generated during 4 weeks home use of the OneTouch® Verio Pro BGMS by 101 individuals with Type 1 or Type 2 diabetes who self-adjust insulin. Participants provided feedback (using pre-defined reason codes or free-text; Table) in home diaries about the patterns they received during routine testing.

**Results:** In total, 987 coded reasons and 199 free-text reasons were recorded (Table). Participant responses were further segregated with respect to before meal high, fasting high or low pattern alerts. Categorizing the coded reasons for such patterns from these participant responses highlighted consistent themes. 37% of before meal high alerts and 46% of fasting high alerts resulted from either snacking or from insufficient basal insulin, respectively. Whereas low alerts (41%) were thought to result from activity of some kind. Categorizing participant free-text reasons also highlighted consistent themes with 21% of before meal high alerts and 21% of fasting high alerts resulting from either food / snacking or from insufficient basal insulin/ wrong carbohydrate ratio, respectively. Whereas low alerts (29%) were thought to result from insufficient food.

**Conclusion:** This study provides insights on how BGMS users interpret on-meter pattern alert messages and identify opportunities for improving glycaemic control. The users' observations may also facilitate conversations with HCP's.

## Participant Responses to Specific Pattern Alerts

Alert Type	n	Coded Reasons
Before meal high	557	Snacking (37%), Miscounting carbohydrates (15%), Insufficient mealtime insulin (14%)
Fasting high	209	Insufficient basal insulin (46%), Snacking at night (32%), Rebound hyperglycemia (21%)
Low	221	Activity (41%), Too much insulin (25%), Miscounting carbohydrates (16%)
<b>Free-text Reasons</b>		
Before meal high	105	Food or snacking (21%), Don't know (14%), Rebound hypoglycemia (13%)
Fasting high	70	Insufficient insulin or wrong ratio to carbohydrates (21%), Food or snack at bedtime (21%), Illness or infection (14%)
Low	24	Insufficient food (29%), Don't know (25%), Too much insulin / over- correcting high glucose (12%)

## 1038

**Accuracy of a blood glucose monitoring system at hypoglycaemic glucose levels: analysis of seven clinical studies**

J. Diago Cabezudo<sup>1</sup>, S. Bellary<sup>2</sup>, H. Cameron<sup>3</sup>, K. MacLeod<sup>3</sup>, J. Ellison<sup>3</sup>, P. Raja<sup>3</sup>;

<sup>1</sup>LifeScan, Johnson & Johnson S.A., Madrid, Spain, <sup>2</sup>Aston University, Birmingham, UK, <sup>3</sup>LifeScan Inc., Milpitas, USA.

**Background and aims:** For individuals with diabetes detection of hypoglycemia is crucial, and blood glucose monitoring systems (BGMs) must therefore be accurate in hypoglycemic ranges. Collecting sufficient data at low blood glucose (BG) levels is difficult; which may explain why evidence of BGMS performance during hypoglycemia is lacking. This analysis evaluated the accuracy of 5 performance-equivalent BGMs using OneTouch<sup>®</sup> Verio<sup>®</sup> test strips at BG levels of < 3.9 mmol/L (70 mg/dL) in 7 separate clinical studies.

**Materials and methods:** The studies were conducted between June 2009 and June 2011. BG testing was performed by trained staff in 2 clinical centers in the UK. All studies were conducted in accordance with standard ISO 15197:2003 testing guidelines. Each study included 100 participants with diabetes. For each participant, duplicate BGMS tests were performed using 3-4 test strip lots per study. BG reference values were obtained using a YSI 2300 STAT Glucose Analyzer before and after BGMS testing.

**Results:** Of a total of 5,400 measurements, 674 (12.5%) were at a BG level of < 3.9 mmol/L (70 mg/dL). The number and percentage of results within  $\pm 0.83$  mmol/L (15 mg/dL) and  $\pm 0.56$  mmol/L (10 mg/dL) were calculated at BG levels < 3.9 mmol/L (70 mg/dL), < 3.3 mmol/L (60 mg/dL), and < 2.8 mmol/L (50 mg/dL). Accuracy of the OneTouch Verio test strips at hypoglycemic blood glucose levels are shown in the Table.

**Conclusion:** Compared with analysis based on a single study, using data from 7 studies, 5 BGMs, and 15 different test strip lots provides a robust depiction of test strip accuracy at BG levels < 3.9 mmol/L (70 mg/dL). The results indicate that OneTouch Verio test strips are highly accurate in the hypoglycemic range. Table. OneTouch Verio accuracy at BG levels < 3.9 mmol/L (70 mg/dL).

	BG values		
	< 3.9 mmol/L (70 mg/dL)	< 3.3 mmol/L (60 mg/dL)	< 2.8 mmol/L (50 mg/dL)
*Within $\pm 0.83$ mmol/L (15 mg/dL), % (n/N)	100.0 (674/674)	100.0 (358/358)	100 (270/270)
Within $\pm 0.56$ mmol/L (10 mg/dL), % (n/N)	98.8 (666/674)	100.0 (358/358)	100 (270/270)

\*ISO 15197:2003 accuracy limits for BG levels < 4.2 mmol/L (75 mg/dL).

## 1039

**Accuracy of self monitoring blood glucose systems in different ranges of blood glucose**

F. Kulozik, I. Platten, C. Hasslacher;  
Diabetesinstitut Heidelberg, Germany.

**Background and aims:** The accuracy of self monitoring blood glucose (SMBG) systems is usually assessed according to the Guidelines of the International Organization for Standardization (ISO). Currently a revision of the relevant standard ISO 15197 presumably resulting in more stringent criteria is in progress. To meet those criteria at least 95% of the SMBG values may not deviate more than 15 mg/dl from the reference values at BG concentrations of < 100 mg/dl and more than 15% at BG concentrations  $\geq 100$  mg/dl respectively. Also a differentiation of BG levels in more than those two ranges is being discussed. Therefore the aim of the present study was to evaluate the accuracy of customary SMBG systems according to various BG ranges.

**Materials and methods:** We evaluated the accuracy of 20 customary SMBG systems according to the currently discussed revised version of ISO 15197, differentiating BG ranges of < 100 mg/dl, 100-149 mg/dl, 150-199 mg/dl, 200-249 mg/dl, and  $\geq 249$  mg/dl. Therefore an increase and decrease of BG values in the range of approximately 50 - 300 mg/dl were induced by administration of carbohydrate intake and / or insulin application in insulin dependent diabetics. Capillary blood samples were taken from the fingertip for laboratory glucose determination by means of Hitado Super GL (glucose oxidase method) as reference and BG values were simultaneously measured in capillary blood from the same location using a SMBG device. The following commercially available glucose meters were tested: AccuChek<sup>®</sup> Compact, AccuChek<sup>®</sup> Mobile, AccuChek<sup>®</sup> Aviva Nano (Roche Diagnostics), BG Star<sup>®</sup> (AgaMatrix Inc), Breeze<sup>®</sup>, Contour<sup>®</sup> Plasma, Contour<sup>®</sup> USB (Bayer Health Care), Fine Touch<sup>®</sup> (Terumo Corp.), Freestyle Lite<sup>®</sup> (Abbott Diabetes Care), GL 40<sup>®</sup> (Beurer Medical), Glucomen LX<sup>®</sup> (Menarini Diagnostics), GlucoSmart<sup>®</sup> Swing (MSP Bodmann), MyLife Pura<sup>®</sup> (Ypsomed AG), Omnitest3<sup>®</sup> (B. Braun), One Touch Ultra<sup>®</sup>, One Touch Verio<sup>®</sup>, One Touch Vita<sup>®</sup> (LifeScan Inc), smartLAB mini<sup>®</sup>, smartLAB sprint<sup>®</sup> (HMM Diagnostics), Wellion Calla<sup>®</sup> (MedTrust). For each SMBG system 200 - 300 pairs of values were obtained.

**Results:** The analyzed SMBG systems showed significant differences concerning the accuracy regarding to the mentioned BG ranges varying from only 70% to often 100% of the values within the ISO criteria. We could demonstrate a high level of accuracy for 7 SMBG systems, i.e. 95% of the values met the ISO standard in at least 4 BG ranges (AccuChek<sup>®</sup> Compact, AccuChek<sup>®</sup> Mobile, AccuChek<sup>®</sup> Aviva Nano, Freestyle Lite<sup>®</sup>, MyLife Pura<sup>®</sup>, One Touch Ultra<sup>®</sup>, One Touch Vita<sup>®</sup>). 9 glucose meters fulfilled the criteria in only 2 or even less BG ranges, the inaccuracy of those devices was found in the lower ranges of BG in particular.

**Conclusion:** The results of the present study proved that only 1/3 of the examined SMBG systems had adequate accuracy in at least 4 of the 5 chosen BG ranges. The glucose meters with insufficient accuracy showed their weakness particularly in the lower ranges of BG.

## 1040

**Inaccuracies found in common SMBG systems: clinical considerations for patients and providers**

R. Brazg<sup>1</sup>, L. Klaff<sup>1</sup>, C. Parkin<sup>2</sup>;

<sup>1</sup>Rainier Clinical Research Center, Renton, <sup>2</sup>CGParkin Communications, Inc., Boulder City, USA.

**Background and aims:** Self-monitoring of blood glucose (SMBG) is an important component of diabetes management. Because SMBG data are often used in clinical decision-making, it is critical that the data be accurate. Several variables (e.g. user technique) can impact the accuracy of SMBG results. In clinical practice the inherent accuracy of the SMBG system itself is often not considered. It is assumed that because all systems marketed in the US met the current international standard ISO 15197:2003 (ISO), they must be accurate. This assumption is not necessarily true; concerns about SMBG accuracy have prompted the development of new criteria for accuracy that require all systems to achieve a performance level whereby  $\geq 95\%$  of the individual glucose results fall within  $\pm 15$  mg/dL of the results of the manufacturer's measurement procedure at glucose concentrations <100 mg/dL and within 15% for values  $\geq 100$  mg/dL. We evaluated the accuracy of 7 currently marketed systems against the current and proposed accuracy criteria: ACCU-CHEK<sup>®</sup> Aviva Plus; Advocate<sup>™</sup> Redi-Code; Element<sup>™</sup>; Embrace<sup>™</sup>; Prodigy<sup>®</sup> Voice; TRUEbalance<sup>™</sup>; and WaveSense Presto<sup>™</sup>.

**Materials and methods:** Capillary blood samples were collected from 162 subjects by deep finger puncture. Results from the SMBG systems were compared to those obtained from each manufacturer's documented reference system, YSI or PCA-HK; 3 different strip lots from each SMBG system were tested with each subject, in duplicate.

**Results:** Evaluated using the current ISO standard ( $\geq 95\%$  within  $\pm 15$  mg/dl for values  $< 75$  mg/dl and  $\pm 20\%$  for values  $\geq 75$  mg/dl), only the ACCU-CHEK Aviva Plus, Element, and WaveSense Presto systems met accuracy criteria; however, only the ACCU-CHEK Aviva Plus met the newly proposed criteria in all 3 lots tested. (Table) The other 6 systems failed to meet the standard in at least 2 of the 3 lots tested, showing lot-to-lot variability, high/low bias and variations due to hematocrit.

**Conclusion:** Whilst only 3 of 7 systems tested met the current ISO accuracy standard, only 1 of 7 met the proposed accuracy criteria. Because SMBG data are frequently used to make therapeutic decisions, inaccurate glucose readings can potentially adversely impact clinical outcomes in people with diabetes. SMBG accuracy is particularly important in the elderly (who are often more susceptible to hypoglycemia) and those with diabetic nephropathy (who are often anemic). Although there are many factors that should be addressed through patient education and training, clinicians can reduce controllable variables, by prescribing accurate and validated SMBG systems. The proposed accuracy criteria should enhance patient safety by improving the accuracy of available SMBG systems. Table. Percentage and number of tests within range: Current ISO and Proposed ISO criteria

SMBG System (Reference Method)	ISO 15197			Proposed ISO 15197		
	Lot 1	Lot 2	Lot 3	Lot 1	Lot 2	Lot 3

### Projection of long term health-economic benefits of continuous glucose monitoring (CGM) versus self monitoring of blood glucose in type 1 diabetes, a UK perspective

S. Roze<sup>1</sup>, P. Lynch<sup>2</sup>, M. Cook<sup>3</sup>

<sup>1</sup>HEVA, Lyon, France, <sup>2</sup>Medtronic International Trading Sarl, Tolochenaz, Switzerland, <sup>3</sup>Medtronic UK, Watford, UK.

**Background and aims:** The main objective of this study was to estimate the impact of Continuous Glucose Monitoring (CGM) compared to Self Monitoring of Blood Glucose (SMBG) on both health and economic outcomes of type 1 diabetes (T1DM) in the UK.

**Materials and methods:** The Core Diabetes Model (CDM) is an internet-based, highly validated, computer simulation model to determine the long-term health outcomes and economic consequences of diabetes interventions. This model was used to project the incidence of diabetes-related complications over a lifetime horizon, based on A) a recently published meta-analysis comparing CGM versus SMBG, with insulin delivery being the same in both arms and B) a real life observational study. The meta-analysis showed that for

the analysed cohort of T1DM with average baseline HbA1c of 10%, every day use of CGM led to a reduction of -1.49% versus -0.62% HbA1c, for CGM and SMBG respectively. The mean baseline age of the simulated cohort was 27 years, with a mean duration of diabetes of 13 years. The observational study recorded a reduction from 7.11 to 4.35 daily blood glucose tests respectively for SMBG and CGM groups. CGM effects also included a decrease in the annual rate of major hypoglycaemic events from 27.7 events per 100 patients' years for SMBG to 15. The quality of life was adjusted for a reduced fear of hypoglycaemic event in the CGM arm. Diabetes related complication costs were UK specific and taken from various published sources. Discount rates were applied on both clinical and economic outcomes respectively at a rate of 1.5% and 3.5% per annum. Sensitivity analyses were carried out on several key parameters.

**Results:** The incremental cost-effectiveness ratio (ICER) was 17,932 GBP (£) per Quality Adjusted Life Year gained (QALY). The improvement in discounted QALY was 1.9 years in favour of CGM. Undiscounted life expectancy was increased by 3.03 year for CGM versus SMBG. Additional CGM related costs were partially offset by the savings due to the reduction in diabetes related complications and the lower frequency of SMBG tests. Remaining extra costs due to CGM were on average 1,361£ per year. CGM usage compared to SMBG increased the mean time alive free from any complications by 2.87 years. In a one-way sensitivity analysis considering no effect on the rate of major hypoglycaemic event for CGM, the ICER was 23,067£/QALY. The one-way sensitivity analysis based on no reduction of fear of hypoglycaemic event due to CGM led to an ICER of 21,336£/QALY. By using an equal discount rate for both health and economic parameters of 3.5%, the ICER was 25,975 £/QALY.

**Conclusion:** Using a well-accepted simulation model in T1DM, projection of the improvement in HbA1c of CGM versus SMBG translated into cost-effective ratio, generally considered as very good value for money in the UK. Extensive sensitivity analysis on key drivers confirmed the robustness of results under a wide range of assumptions. This analysis did not include indirect costs, which would have led to even better health-economic results from a societal perspective.

### 1042

#### Accuracy and acceptability of the 6-day Enlite continuous subcutaneous glucose sensor

S.W. Lee<sup>1</sup>, T. Bailey<sup>2</sup>, R. Brazg<sup>3</sup>, M. Christiansen<sup>4</sup>, A. Ahmann<sup>5</sup>, R. Henry<sup>6</sup>, S. Garg<sup>7</sup>, E. Watkins<sup>8</sup>, F.R. Kaufman<sup>1</sup>

<sup>1</sup>Medtronic, Inc., Northridge, <sup>2</sup>AMCR Clinic, Inc., Escondido, <sup>3</sup>Rainier Clinical Research Center, Renton, <sup>4</sup>Diablo Clinical Research, Walnut Creek, <sup>5</sup>Oregon Health and Science University, Portland, <sup>6</sup>University of California San Diego, <sup>7</sup>University of Colorado, Denver, Aurora, <sup>8</sup>Profil Institute for Clinical Research, Chula Vista, USA.

**Background and aims:** The Enlite subcutaneous glucose sensor was previously evaluated in adults and children and shown to be accurate for 6 days, durable, and acceptable to patients and parents/caregivers. We evaluated its accuracy using abdominal insertion sites at a wide range of glucose concentrations and at different rates of glucose concentration change.

**Materials and methods:** A pivotal 6-day trial in adults was conducted at 7 US investigational centers. Sensors were self-inserted and taped. Each patient wore 1 or 2 sensors on the abdomen and these sensors were calibrated 3–4 times per day throughout the study. Accuracy was evaluated vs frequently-sampled YSI plasma glucose values. The frequent sampling tests lasted for 12 hours on days 1, 3, and 6. Hypoglycemia (to  $\leq 75$  mg/dL) and hyperglycemia (to  $\geq 180$  mg/dL) were induced on day 1 (beginning immediately after initial calibration), day 3, and day 6. Accuracy was assessed on different days (1, 3, and 6) and at different glucose concentration ranges ( $\leq 75$  mg/dL, 75–180 mg/dL, and  $> 180$  mg/dL). Accuracy of calibration was also assessed at rapid, moderate, and slow absolute rates of change (|ROC|) ( $> 2$ , 1–2,  $< 1$  mg/dL/min, respectively). Patient satisfaction with Enlite was also evaluated with a 7-point Likert-type questionnaire.

**Results:** Adults with type 1 (N=65) or type 2 (N=25) diabetes (mean age 44, range 18–71) participated. The Table shows mean and median absolute relative differences (ARD) between sensor and YSI glucose concentrations by day and by glucose range. Mean self-reported survey responses were 5.9/7 for “ease of use,” 6/7 for “comfort,” 5.9/7 for “ease of insertion,” and 5.8/7 for “would recommend.” The overall mean (median) absolute relative differences (ARD) were 13.6% (10.1%). At rapid ROC the mean (median) ARD were 16.3% (12.9%), at moderate ROC were 12.9% (9.6%), and at slow ROC were 13.6% (10.1%). There were no device-related adverse events.

**Conclusion:** We conclude that the Enlite sensor is accurate, durable, comfortable, safe, and easy to use. It is accurate during periods of stable or changing glucose concentrations and met predefined success criteria for agreement with YSI values at all glucose ranges. Improvements in continuous glucose sensing should expedite development of semiautomated insulin delivery features in modern pumps.

Enlite sensor accuracy by mean and median absolute relative differences				
By Day	Overall	Day 1	Day 3	Day 6
Mean (Median) ARD	13.6% (10.1%)	15.9% (12.2%)	11.8% (9.1%)	13.2% (9.6%)
By Glucose Range	Overall	$< 75$ mg/dL	75–180 mg/dL	$> 180$ mg/dL
Mean (Median) ARD	13.6% (10.1%)	10.8* (8.5*)	12.7% (9.4%)	12.0% (9.0%)

\* , mean absolute differences (mg/dL)

### 1043

#### Comparison of three continuous glucose monitoring systems with six sensors per subject in parallel

M. Link<sup>1</sup>, G. Freckmann<sup>1</sup>, S. Pleus<sup>1</sup>, E. Zschorneck<sup>1</sup>, C. Haug<sup>1</sup>, H.-M. Klötzer<sup>2</sup>, E. Ramstetter<sup>3</sup>, W. Schmidt<sup>3</sup>, M. Schoemaker<sup>3</sup>

<sup>1</sup>Institute for Diabetes-Technology GmbH, Ulm, <sup>2</sup>HMKQ, Weinheim, <sup>3</sup>Roche Diagnostics GmbH, Mannheim, Germany.

**Background and aims:** The aim of this study was to compare 3 commercially available needle-type continuous glucose monitoring (CGM) systems

following the CLSI guideline POCT05 “Performance Metrics for Continuous Interstitial Glucose Monitoring” under daily life conditions.

**Materials and methods:** Twelve people with type 1 diabetes (age:  $47.7 \pm 6.9$  years (mean  $\pm$  standard deviation), HbA<sub>1c</sub>  $8.2 \pm 1.4$  %, duration of diabetes:  $23.7 \pm 9.9$  years) wore 6 sensors in parallel, two sensors each of the 3 following CGM systems: FreeStyle Navigator™, DexCom™ Seven® Plus 3<sup>rd</sup> Generation and Guardian® REAL-Time with Enlite Sensor. Each system was used for one sensor lifetime, which was 5 days for the FreeStyle Navigator™, 6 days for the Guardian® REAL-Time or 7 days for the DexCom™ Seven® Plus. CGM measurements were paired to capillary blood glucose (bG) measurements (approximately 30 per day and subject). Performance was characterized by mean absolute relative differences (MARD) between CGM and paired bG measurements and percentage absolute relative difference (pARD), which is the average of the absolute relative differences between paired CGM measurements of the first and the second sensor of each system.

**Results:** Average data reporting percentages ranged from 95.9 % (DexCom™ Seven® Plus) to 98.9 % (Guardian® REAL-Time) of the time worn. Capillary bG measurements ranged from 35 to 446 mg/dL. MARD and pARD are reported in the table (mean  $\pm$  standard deviation [range]). All systems could be worn for nearly 100 % of their estimated lifetime (FreeStyle Navigator™: 100.6 %, DexCom™ Seven® Plus: 98.3 % and Guardian® REAL-Time: 99.0 %) before the sensors had to be removed.

**Conclusion:** The 3 CGM systems tested showed good overall performance, with the FreeStyle Navigator™ achieving lower sensor-to-bG differences and sensor-to-sensor differences than the DexCom™ Seven® Plus 3<sup>rd</sup> generation and the Guardian® REAL-Time with Enlite Sensor.

Mean and percentage absolute relative differences for the CGM systems tested.

CGM system	MARD	pARD
FreeStyle FreeStyle Navigator™	12.4 $\pm$ 3.6 % [8.4 - 19.0 %] (n = 24)	10.1 $\pm$ 4.1 % [5.2 - 17.6 %] (n = 12)
DexCom™ Seven® Plus	16.7 $\pm$ 3.8 % [12.7 - 29.2 %] (n = 24)	15.4 $\pm$ 4.2 % [9.2 - 23.5 %] (n = 12)
Guardian® REAL-Time	16.4 $\pm$ 6.9 % [7.5 - 23.9 %] (n = 24)	18.1 $\pm$ 6.5 % [9.2 - 31.2 %] (n = 12)

#### HbA<sub>1c</sub> and mean glucose in insulin treated diabetes using the SevenPlus continuous glucose monitor (CGM): correlation and intra-patient consistency over time

N.B. Argento<sup>1</sup>, K. Nakamura<sup>2</sup>, R. Sala<sup>2</sup>

<sup>1</sup>Maryland Endocrine and Diabetes Center, Columbia, <sup>2</sup>Dexcom, Inc., San Diego, USA.

**Background and aims:** The relationship between HbA<sub>1c</sub> and mean glucose (MG) is controversial. An estimated HbA<sub>1c</sub> derived glucose (eAG) is said to be useful, but CGM data shows significant variation between the eAG and CGM measured MG (CMG). Little information is available on the consistency of the eAG-CMG relationship in an individual patient over time. We report the eAG-CMG relationship in a large group of insulin requiring diabetes patients using home CGM in a real world setting, and the consistency of this relationship in a subgroup of patients in whom more than one eAG-CMG value was available.

**Materials and methods:** Patients using the SevenPlus CGM at home have their CGM device downloaded for review as part of their routine clinic evaluation. Clinic data were reviewed, and an HbA<sub>1c</sub>-CMG data pair was included if there was more than 50% utilization of CGM in the 60 days prior to the HbA<sub>1c</sub>. A subgroup had between 2 to 6 data pairs available. A linear regression model for eAG-CMG was derived from the most recent data pair for each unique patient (n=139) and eAG-CMG consistency, measured by variance and range within a patient, were also evaluated in patients with multiple eAG-CMG pairs (n=91, mean values per patient 3.3).

**Results:** The mean age was 48.7 yr (18–75). Their diabetes duration was 26 yr (1–58). 61% were male. 91% had T1D and 9% had T2D. 80% were on CSII and 20% were on MDI treatment. The mean CGM utilization of the study population was 80% of maximal possible use. Figure. CMG (mgdl) =  $18 + 19.484 A_{1c}$ . The CMG for A<sub>1c</sub> 7.0% = 154.4 mg/dL (8.58 mmol/L). For pa-

tients with multiple eAG-CMG pairs, the residual between CMG and eAG ( $\text{CMG} - \text{eAG} / \text{eAG} \times 100$ ) was calculated for each eAG-CMG pair. Patients tended to trend consistently over multiple eAG-CMG determinations. For some patients, these differences have important clinical implications. For example, subj 1: CMG 192 mg/dL, eAG 156 mg/dL, residual 18.7%; CMG 212 mg/dL, eAG 158 mg/dL, residual 25.5%, difference of residuals 6.8%. Subj 2: CMG 145 mg/dL, eAG 174 mg/dL, residual -20.1%; CMG 142 mg/dL, eAG 160 mg/dL, residual -13.1%, difference 7.0%. The mean variance of residuals was 4.42%. The mean maximal difference between residuals was 7.3%. 74.8% of patients had a maximal difference between residuals of 10% or less (36.3% < 5.1%, 38.5% 5.1–10.0%, mean 5.04%), and 5.5% had a maximal difference >15% (mean=19.8%). For this small group with high variation of residuals, there was no significant difference in % CGM use, CMG or the CGM standard deviation of glucose values.

**Conclusion:** The SevenPlus CGM yields a similar eAG-CMG correlation to the JDRF CGM study. There is significant variation in the eAG and CMG in individual patients. Some subjects have striking differences between eAG and CMG, which has important clinical implications. The individual eAG-CMG relationship tends to trend consistently over time in most patients. Clinicians should consider modification of  $\text{HbA}_{1c}$  goals in patients with persistent significant divergence of eAG and CMG.

## 1045

### Performance of a microdialysis-based continuous glucose monitoring (CGM) system

E. Zijlstra<sup>1</sup>, T. Heise<sup>1</sup>, W. Künnecke<sup>2</sup>;

<sup>1</sup>Profil Institute for Metabolic Research, Neuss, <sup>2</sup>Trace Analytics GmbH, Braunschweig, Germany.

**Background and aims:** Combining intravenous microdialysis with on-line glucose analysis for CGM may prove to become an important development to achieve tight glycaemic control in hospitalised patients without blood loss, measurement delays or frequent manual interventions. In this study we evaluated the performance of a microdialysis-based CGM system for up to 48 hours use.

**Materials and methods:** Twenty-one healthy adult subjects were connected to 1 or 2 microdialysis-based CGM systems. Blood glucose was sampled automatically and without blood loss by means of microdialysis at least every 2 minutes. The dialysate containing the sampled glucose was analysed immediately by an on-line glucose sensor. The glucose sensor was calibrated prior to the start of an experiment and once more after 24 hours in experiments lasting for 48 hours. Reference blood samples were taken manually and analysed using a laboratory glucose analyser every 10–60 minutes. The subjects consumed meals or glucose was administered orally or intravenously to analyze the accuracy of the CGM system over a range of blood glucose concentrations.

**Results:** A total of 1796 paired sensor-reference data points were evaluated. Mean relative deviation was 9.4% overall, with only small deviations between hypoglycaemic (< 70 mg/dL), euglycaemic (70–180 mg/dL) and hyperglycaemic (> 180 mg/dL) glucose ranges (11.0%, 8.8% and 12.6% respectively). According to the current ISO15197 criteria 91.4% of data points were accurate. Good performance in the hypoglycaemic range is notoriously difficult, but

the first results with this new system are very encouraging: Below 75 mg/dL, 94.6% of the sensor values were accurate (within 15 mg/dL of the reference value). Clarke Error Grid analysis showed that 99.3% of the data points were located within the accurate and acceptable zones, Zone A & B. The remaining datapoints were located within Zone D (0.6%) and Zone E (0.1%).

**Conclusion:** This study shows that CGM using microdialysis in blood is feasible for up to 48 hours and provides reasonably accurate glucose results with only a once-daily calibration. Improved calibration and/or referencing strategies may increase the accuracy of the system further in future studies.

### Clarke Error Grid Analysis

## 1046

### Performance and reliability of the new Dexcom G4™ continuous glucose monitoring (CGM) System- Pivotal trial results

D. Price<sup>1</sup>, T. Bailey<sup>2</sup>, M. Christiansen<sup>3</sup>, E. Watkins<sup>4</sup>, D. Liljenquist<sup>5</sup>, K. Nakamura<sup>1</sup>;

<sup>1</sup>Dexcom, Inc, San Diego, <sup>2</sup>AMCR Institute, Inc, Escondido, <sup>3</sup>Diablo Clinical Research, Walnut Creek, <sup>4</sup>Profil, Chula Vista, <sup>5</sup>Rocky Mountain Diabetes and Osteoporosis Center, Idaho Falls, USA.

**Background and aims:** Since the first real-time CGM systems were approved, accuracy and reliability have been a concern for some patients and clinicians. We report on the results of a study for the new CGM which found improvements in performance and reliability compared with previous CGM systems due to changes in the sensor design, sensor materials, algorithm, and transmitter.

**Materials and methods:** The study enrolled 72 adult subjects (≥18 yrs, 83%T1DM, 17%T2DM) at 4 US centers. Subjects wore sensors for up to 7 days and 36 subjects wore two sensors concurrently to evaluate system precision. Patients calibrated their CGM using self-monitored blood glucose (SMBG) values obtained every 12 hours with a OneTouch Ultra 2 blood glucose meter. Subjects were in-clinic for 12 hours on days 1, 4 and 7 to have glucose deliberately raised and lowered so as to test the performance of the CGM over the entire measurement range (2.2 to 22 mmol/l) of the device. CGM readings were compared against Yellow Springs Instrument (YSI) reference plasma glucose measurements acquired from venous samples every 15 minutes.

**Results:** There were a total of 9,093 temporally matched points between the new CGM and YSI reference value. The global accuracy of the system was 13.2 % Mean ARD with a Median ARD of 9.5%. 80% of all points were in the Clarke Error Grid (CEG) A zone. CGM accuracy improved over the seven days of sensor wear. The Mean ARD on day 1 was 16.6% compared with 11.3% on day 4 and 11.8% on day 7. 85% of percent of all CGM glucose results obtained in-clinic on days 4 and 7 were in the CEG A zone (see figure), approaching the accuracy of BG meters during home use. Accuracy in the hypoglycemic region (2.2–4.4 mmol/l) was 0.7 mmol/l Mean Absolute

Difference and 83% of the data was within 1.1 mmol/l of the YSI values. 75% of all points in this range were in the CEG A zone. In overt hypoglycemia (YSI values less than 3.5 mmol/dL), greater than 90% of temporally matched new CGM values were less than 4.3 mmol/l. The average coefficient of variation was 6.6%, better than previous published CGM results and within the reported precision of some BG meters. The new CGM has a high degree of reliability as measured by the percentage of sensors lasting for the full 7 days of intended use and the percentage of potential values (up to once every 5 minutes) that were actually displayed. 94% of sensors that were successfully inserted lasted the entire 7 days of wear. 98% of potential glucose values were displayed to subjects.

**Conclusion:** The new CGM demonstrates improved performance and reliability compared to currently marketed CGM devices and should provide greater confidence to patients using CGM as part of their clinical decision making. This may result in greater patient adoption and retention and further improve clinical outcomes.

Clinical Trial Registration Number: NCT01514292

## 1047

### A new and innovative method for objective evaluation of CGM profiles to structure diagnosis and therapy in type 2 diabetes

E. Salzsieder<sup>1,2</sup>, P. Heinke<sup>1</sup>, L. Vogt<sup>2</sup>, P. Augstein<sup>1,2</sup>;

<sup>1</sup>Institute of Diabetes „Gerhardt Katsch“ Karlsburg, <sup>2</sup>Diabetes Service Center, Karlsburg, Germany.

**Background and aims:** Continuous glucose monitoring (CGM) has a high potential to improve significantly diabetes care and management. However, an easy, objective and practicable tool to evaluate the quality of measured glucose profiles is missing. The aim of our study was therefore to develop an evaluation score (Q-score) that considers all aspects of CGM profiles and can be applied for a complex and objective analysis.

**Materials and methods:** 1495 registered CGM profiles provided the database for this study. First, a factor analysis addressing all quality affecting parameters (mean sensor glucose, intra- and inter daily variability, time and area above or below target range) was performed to identify factors with major impact on CGM. For each factor one parameter was selected and used for the development of the Q-score.

**Results:** This study resulted in Q-score for quality assessment of CGM profiles. To verify the Q-score two diabetes specialists (DS) diagnosed independent 729 and 194 CGM profiles of type 2 diabetic patients, respectively. The results were analysed for the inter-individual variation as well as correlated with parameters for CGM profiles such as mean sensor glucose,  $\pm$ SD, MODD. There was a high correlation between the Q-score and the results of both DS (Kendalls-Tau= 0.766 and 0.719;  $p < 0.001$ ). Both DS showed a high correlation between (Kendalls-Tau=0.763;  $p < 0.001$ ), although one DS gave a better diagnosis (McNemar-Bowker-Test  $p < 0.001$ ). To establish an easy and practicable diagnosis tool the Q-score was tested for categorisation of CGM profiles. 729 profiles were categorised by one DS in very good (Q-score:  $3.4 \pm 0.8$ ), good ( $4.9 \pm 1.2$ ), satisfactory ( $7.1 \pm 1.6$ ), borderline ( $10.0 \pm 1.9$ ) and not satisfactory ( $13.8 \pm 2.6$ ). The Q-score was also correlated with HbA1c ( $r = 0.50$ ), mean sensor glucose (0.68), range (0.88), MODD (0.63) and time above (0.86) and below (0.24) target range.

**Conclusion:** The Q-score combines all essential quality criteria for describing blood glucose profiles in only one parameter. The Q-score is independent

of subjective opinions and can be used therefore for automatic evaluation of CGM curves. The Q-score has the potential to become a practical tool in diagnosis and therapy of type 2 diabetic patients.

## 1048

### Characteristics of real-life glucose profiles monitored by continuous glucose monitoring system in people with normal glucose tolerance

W. Xu, J. Yan, Y. Zhu, G. Zhang, X. Yang, L. Zeng, J. Weng;

Department of Endocrinology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

**Background and aims:** Normal glucose tolerance (NGT) is diagnosed based on OGTT which is considered as the “gold standard”. However, OGTT, even self-monitoring of blood glucose (SMBG) by using portable blood glucose meter, is not able to reveal the real-life glucose profiles. Therefore, detailed information of glucose profiles in people with NGT is poorly studied before continuous glucose monitoring system (CGMS) has been widely used. This study aims to investigate the characteristics of real-life glucose profiles in people with NGT by CGMS.

**Materials and methods:** 40 participants (23 males, 17 females) with NGT confirmed by OGTT were enrolled in this study. Fasting blood samples were collected for measurement of fasting plasma glucose (FPG), hemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>), lipid profiles, fasting insulin, and fasting C peptide. Homoeostasis model assessment was used to estimate basal  $\beta$ -cell function (HOMA B) and insulin resistance (HOMA-IR). All participants completed a 3-day period of glucose monitoring using CGMS. The 24-h mean blood glucose (MBG), standard deviation of MBG (SDBG), mean amplitude of glycemic excursions (MAGE), largest amplitude of glycemic excursions (LAGE) and means of daily differences (MODD) were calculated with the data obtained from CGMS. The protocol and informed consent document were approved by the research ethics board of our University. All patients gave written informed consent.

**Results:** This population were  $45 \pm 11$  years old, with body mass index  $25 \pm 8$  Kg/m<sup>2</sup>, FPG  $4.9 \pm 0.3$  mmol/L, HbA<sub>1c</sub>  $5.4 \pm 0.5\%$ , triglyceride  $2.0 \pm 1.3$  mmol/L, total cholesterol  $5.1 \pm 0.9$  mmol/L, LDL-C  $3.1 \pm 0.8$  mmol/L, HDL-C  $1.3 \pm 0.3$  mmol/L. MBG, SDBG, MAGE, LAGE and MODD were  $6.0 \pm 0.7$  mmol/L,  $0.9 \pm 0.1$  mmol/L,  $1.9 \pm 0.8$  mmol/L,  $2.9 \pm 1.4$  mmol/L and  $1.1 \pm 0.1$  mmol/L, respectively. 14 NGT participants experienced asymptomatic hypoglycemia defined as glucose concentration  $< 3.9$  mmol/L by CGMS. 72.5% (29/40) participants reached glucose concentrations above 7.8 mmol/L for  $5.2 \pm 4.6$  hours. When compared with participants whose glucose concentrations within 7.8 mmol/L, in addition to presenting higher glucose concentrations (FPG:  $5.0 \pm 0.4$  vs.  $4.8 \pm 0.3$  mmol/L, MBG:  $6.4 \pm 0.7$  vs.  $5.7 \pm 0.5$  mmol/L), participants with glucose concentrations above 7.8 mmol/L showed more obvious glycemic excursions, represented by higher SDBG, MAGE, LAGE and MODD (see table). There is no difference in HbA<sub>1c</sub>, lipid profiles, fasting insulin, fasting C peptide, HOMA B and HOMA-IR between 2 groups.

**Conclusion:** CGMS provides more detailed information of real-life glucose profiles in people with NGT. 72.5% NGT participants in this study spent a considerable amount of time at glucose levels considered to be “prediabetes” or even “diabetes”, characterized by more predominant glycemic excursions.

Comparison of participants whose glucose above 7.8 mmol/L and those with glucose within 7.8 mmol/L

	FPG (mmol/L)	MBG (mmol/L)	SDBG (mmol/L)	MAGE (mmol/L)	LAGE (mmol/L)	MODD (mmol/L)

## New method for measuring the velocity and magnitude of directional glucose level movement of continuous glucose monitoring

A. Konyashin<sup>1</sup>, E. Patrakeeva<sup>2</sup>;<sup>1</sup>Saint-Petersburg State Technical University, <sup>2</sup>Saint-Petersburg Medical University, Russian Federation.

**Background and aims:** At the present time, growing popularity of continuous glucose monitoring (CGM) in T1DM patients gives diabetologists great amounts of data, which can be applied to analyze patients' glucose variability and, further, estimate pathogenesis of development of diabetes complications. Moreover, glucose level movement in patients with diabetes goes in trends. Many variables influence on trends, they lead actual developments in underlying fundamental conditions. In everyday practice, diabetologists require relatively quick and easy to use method to anticipate future trends without concern for underlying causes and effects. Therefore, aim was to design method for estimating glucose variability and identifying glucose level movement trend by measuring the velocity and magnitude of directional glucose level movement of CGM.

**Materials and methods:** 8 patients with T1DM CGM was performed for consecutive 6 days. The range of glucose movement over each 4-hours interval was represented with candlestick chart (Fifth International ATTD Conference). Special LabVIEW software was developed to quantify glucose level momentum using the Relative Strength Index (RSI), one of the most popular stock market price momentum indicators. Mathematically, RSI is represented as:  $RSI = 100 - (100/(1+RS))$ , where RS is the ratio of the average of n-period glucose level increases divided by the absolute value (i.e., ignoring sign) of the average of n-period decreases. The RSI computes momentum as the ratio of higher rises to lower losses: T1DM patients which have had more or stronger glucose level rises have a higher RSI than patients which have had more or stronger falls.

**Results:** RSI is a leading indicator of a change in trend direction. In a typical cycle, glucose level begins a new uptrend with very high and rising momentum. This positive velocity gradually diminishes as glucose reaches high level, as patients use insulin for treatment. The slope of the glucose level advance lessens. Almost invariably, momentum hits its peak well before the glucose hits its ultimate high. RSI decreases more dramatically as glucose rallies begin to fall short of previous peaks on minor rally attempts, depicting a very mature phase of insulin therapy effects.

**Conclusion:** RSI can be classified as a glucose level momentum oscillator, measuring the velocity and magnitude of directional movements. Usage of RSI is a good attempt to offer an objective and orderly procedure for quantifying glucose variability and identifying glucose level movement trend. It depends solely on the changes in glucose level.

## 1050

## Simulation models for population glucose distributions and individual glucose trends

C.C. Palerm, L. Desborough;

R&amp;D, Medtronic, Inc., Northridge, USA.

**Background and aims:** Development of products and services for the management of diabetes are best done using robust design methods, which requires experimentation. Models are an essential tool, as clinical trials are too time consuming and expensive for early design efforts. To accelerate development of future products and services, two simple simulation models of glycemia in people with type 1 diabetes were developed.

**Materials and methods:** The Population Static Glucose Distribution (PSGD) and Individual Subject Glucose Trend (ISGT) models were parameterized on random samples drawn from over 4000 subject-months of continuous glucose monitoring (CGM) data. Both models assume a log-normal blood glucose distribution and have been extensively validated. The PSGD was modeled using a bivariate log-normal probability distribution with zero correlation. It has four parameters: the mean ( $\mu$ ) and standard deviation ( $\sigma$ ) of both the BG values themselves and the BG standard deviation, such that  $\log_{10}(BG [mg/dL]) \sim \text{Normal}(\mu, \sigma)$  where  $\log_{10}(\mu) \sim \text{Normal}(2.09, 0.08)$  and  $\log_{10}(\sigma) \sim \text{Normal}(0.15, 0.028)$ . The notation  $X \sim \text{Normal}(\mu, \sigma)$  indicates that values of X are from a normal distribution with mean of  $\mu$  and standard deviation of  $\sigma$ . ISGT was modeled using a second order autoregressive time series driven by independent, identically distributed, white Gaussian noise. The series is first log-transformed and mean-centered. Its four parameters provide simulated CGM data. For a given  $\mu$  and  $\sigma$  from the PSGD model:  $\log_{10}(G_t) = \gamma_1 + \log_{10}(\mu) + \phi_1 y_{t-1} + \phi_2 y_{t-2} + a_t$  where  $\phi_1 = 1.6442$ ,  $\phi_2 = -0.6493$ ,  $a_t \sim \text{Normal}(0, \sigma_a)$ , and  $\sigma_a = \log_{10}(\sigma)((1 + \phi_2)/(1 - \phi_2)^2 - \phi_1^2)^{0.5}$ .

**Results:** The PSGD model has been used to estimate population glycemic variability and hypoglycemia risk, to evaluate and develop glycemia metrics, and to design "virtual clinical trials" in the artificial pancreas project. A population of "virtual subjects" is created to have the same characteristics as described by the PSGD model. These individuals are created using the ISGT model, and have been used to design user interfaces and develop artificial pancreas control and prediction algorithms. Tracings of simulated CGM data from the ISGT model are indistinguishable from patient data (see Figure).

**Conclusion:** The PSGD and ISGT models have enabled model-based development, rapid prototyping, concept engineering, and robust design. These models allow for more exploration of algorithms in a shorter time than traditional techniques, and can be used to accelerate innovation in diabetes technologies and treatments.

## 1051

## Impact of study design and analytic techniques on the reported accuracy of continuous glucose monitoring (CGM) systems

P. Simpson, T. Peyser, D. Price, A. Garcia, K. Nakamura;

Dexcom, San Diego, USA.

**Background and aims:** CGM performance is an important factor determining a patient's consistent use and clinical benefit. Accuracy, reliability and ease of use should be considered by clinicians when recommending a CGM sys-

tem. Commonly used metrics are often compared across systems; however, these comparisons are challenging due to differences in reported metrics, clinical trial design, and data analysis methods. Consistency in evaluating and reporting CGM performance is important for proper assessment of systems. As an example, CGM performance is often worst on the first and last days of use and studies that minimize data from those days may be misleading. Clinical trials with limited data in the hypo- or hyperglycemic zone or limited rates of change can distort the appearance of overall sensor performance. Real time systems for commercial use by patients typically require a prospectively determined calibration curve using SMBG meters. However, data with increased frequency of calibration, a retrospective calibration optimized for each sensor, or calibration with clinical analyzers rather than SMBG can affect apparent accuracy. Some studies report median, instead of mean differences from reference glucose, negating the impact of outlier data and impacting the accuracy perception. Studies commonly exclude data, but the amount of data excluded and the criteria for exclusion often lack transparency. Some studies report combined Clarke Error Grid A and B zones as a way of improving the perceived accuracy.

**Materials and methods:** Data from a large scale pivotal trial of Dexcom's G4 CGM system was analyzed using different methods to show the effects of frequent calibration and excluding selected data on the performance metrics of the system.

**Results:** The study enrolled 72 adult subjects (83%T1DM, 17%T2DM) at 4 US centers. Patients calibrated their CGM using a self-monitored blood glucose (SMBG) meter twice per day and were in-clinic for 12 hours on days 1, 4 and 7 to have glucose manipulated and to measure Dexcom G4 performance against YSI reference venous glucose every 15 minutes. 15% of the data were in the Hypoglycemic zone (40–80 mg/dl). The data are presented as generated in the clinical trial and also post-processed with a prospective algorithm using four calibrations per day, excluding data from the hypoglycemic zone and excluding data from the first day of patient wear.

**Conclusion:** Different study designs and methods of analysis confound the ability to compare accuracy of different CGM systems and can influence the reported results by 20% or more. There is a need for standardized study designs and metrics to allow such comparisons.

## PS 089 Continuous glucose monitoring with pumps

1052

### Routine use of personal continuous glucose monitoring system with insulin pump in Sweden

P. Lynch<sup>1</sup>, S. Attvall<sup>2</sup>, S. Persson<sup>3</sup>, C. Barsoe<sup>4</sup>, U. Gerdtham<sup>3</sup>;

<sup>1</sup>Medtronic, Tolochenaz, Switzerland, <sup>2</sup>Diabetes Centre, Sahlgrenska University Hospital, Gothenburg, Sweden, <sup>3</sup>The Swedish Institute for Health Economics (IHE), Lund, Sweden, <sup>4</sup>Medtronic Denmark A/S, Copenhagen, Denmark.

**Background:** In 2009, the Swedish Dental and Pharmaceutical Benefits Agency (TLV) concluded that personal Continuous Glucose Monitoring (CGM) when used in combination with the Medtronic Paradigm<sup>®</sup> insulin pump should be included in the Swedish reimbursement system for specific patient indications. To support ongoing reimbursement, data was collected on the clinical and economic parameters of CGM in type 1 diabetes patients in the Swedish clinical practice.

**Methods:** The study was designed as a national multi-center, non-interventional Post-Market-Release Study. Fourteen adults and pediatric centres in Sweden participated. The data were collected both retrospectively and prospectively from medical records and patient questionnaires from May to December 2011. Data was collected regarding HbA1c-level, quality of life (QoL), frequency of hypoglycaemia, and patient preferences using Willingness to Pay (WTP). The HbA1c levels were analysed in the baseline period (0–9 months prior to CGM) and in 3 month intervals after CGM treatment was initiated, reflecting 3 month cycles of routine visits to the clinics. A mean value per patient was used if several HbA1c values were available during the baseline period or any of the 3 month follow-up periods. HbA1c values are reported in NGSP% and Mmol/mol. Inclusion criteria were Type 1 diabetes patients on pump therapy for 3+ months and either an HbA1c  $\geq$  7.9% or 2+ severe hypoglycaemic events in past 12 months or 10+ SMBG tests per day on average.

**Results:** Sixty-nine patients were included in the study. Results show a gradual decrease in HbA1c level from 8.45% in the baseline period before CGM start to 7.64% after 18–21 months of CGM treatment (a -0.81% reduction). The most rapid decrease was observed in the first year of treatment (8.45% to 7.81%, a -0.64% decrease). When using the baseline HbA1c level at the time of starting CGM (available for 13 patients), the treatment resulted in a -1.4% decrease in HbA1c after 1 year of CGM treatment (9.2% baseline to 7.8% after one year). Using an OLS model, adjusting for age and gender, a significant ( $p < 0.05$ ) reduction in HbA1c was observed of -0.62% and -1.06% after 9–12 and 18–21 months of CGM treatment, respectively. The frequency of severe hypoglycaemic events was slightly higher before the start of CGM, as reported both in medical records and by the patients (medical records: 0.10 vs. 0.02 events/month in 6 months before and after CGM start, respectively,  $p = 0.0021$ ). The number of finger sticks decreased by an average of 2.69 tests per day with CGM treatment (7.11 v 4.35,  $p < 0.0001$ ). On average 4 sensors were used per month. No significant change in QoL (measured using a VAS scale) was found from baseline to follow-up. Nevertheless, evidence of a significant WTP for CGM treatment was found; 91% preferred CGM and the average WTP for CGM was SEK 727 (EUR 82) per month when including all respondents and SEK 822 (EUR 93) when including only respondents with positive WTP.

**Conclusion:** This study indicates CGM in the real world setting significantly reduces HbA1c, number of daily finger sticks, and may reduce severe hypoglycaemic events. Although no significant change in QoL was demonstrated, patients WTP for CGM is very high. This study also confirms that initial analyses demonstrating the cost-effectiveness of CGM used to obtain reimbursement in Sweden are based on decent assumptions.

## 1053

**The impact of bolus calculator and wireless communication with blood glucose meter on metabolic control in children with type 1 diabetes mellitus - randomised control trial**

A. Ramotowska, A. Szybowska, M. Lipka, M. Procnier- Czaplińska, H. Trippenbach- Dulaska;  
Medical University of Warsaw, Poland.

**Background and aims:** Bolus calculator is one of the advanced functions in modern insulin pumps models. Together with wireless communication with blood glucose meter potentially facilitates achieving the target post prandial glucose levels. In this RCT authors assessed whether use of wireless communication between compatible devices: Medtronic MiniMed insulin pump and blood glucose meter Contour Link, Bayer results in more frequently bolus calculator using and what is the impact of exerting this tool on metabolic control in type 1 diabetic patients.

**Materials and methods:** 131 children (66 girls, 65 boys) with T1DM for over one year were included into analysis. The mean age was 12.9 yrs (7-17, SD 2.8), mean diabetes duration 5 yrs (1- 14.2, SD 3.2), mean HbA1c 7.1% (5-10.2, SD 1). Subjects were randomly assigned to the one of three groups: A- patients using bolus calculator wirelessly communicated with blood glucose meter, B- patients using bolus calculator without communication with blood glucose meter or C- control group. The primary outcomes were HbA1c level and post prandial glucose level.

**Results:** HbA1c level did not significantly differ between the groups after the 3 months of observation: group A vs B (median 7.05 vs 7.2%;  $p=0.247$ ), group B vs C (median 7.2 vs 6.9%;  $p=0.066$ ). There were also no significant differences between daily dose of insulin between the groups: group A vs B (0.82 vs 0.76 u/kg/d;  $p=0.195$ , group B vs C (0.76 vs 0.82 u/kg/d;  $p=0.212$ ). No statistically differences were observed between the groups in regard to post prandial blood glucose levels: group A vs B (151.7 vs 153.8 mg/dl;  $p=0.333$ ), group B vs C (153.8 vs 145.2 mg/dl;  $p=0.185$ ). Patients in group A use bolus Wizard statistically more frequently compared to group B patients: group A vs B (4.5 vs 2.3/day;  $p=0.002$ ). Patients using wireless communication between insulin pump and blood glucose meter were more satisfied and motivated in the diabetes management (35 vs 27 subjects;  $p=0.005$ ). Incidence of self blood glucose monitoring per day was similar in all groups : group A vs B (5.2 vs 5.5 measurements/day;  $p=0.622$ ), group B vs C (5.5 vs 6.2 measurements/day;  $p=0.279$ ). There was no differences in the number of correctional boluses per day: group A vs B (34.1 vs 37.3 boluses/day;  $p=0.683$ ) as well as percentage of glucose measurements above (group A vs B 44 vs 51%;  $p=0.384$ , group B vs C 54 vs 47%;  $p=0.149$ ) and below (group A vs B 11 vs 8.8%;  $p=0.204$ , group B vs C 8.8 vs 12.2%;  $p=0.064$ ) the target.

**Conclusion:** Bolus calculator using dose not significantly influence on HbA1c level and post prandial glycaemic control but gives patients more satisfaction from the treatment. Patients using wireless communication with blood glucose meter use bolus calculator more frequently.

## 1054

**Feasibility of adjacent insulin infusion and glucose sensing via the Combo-set**

D.N. O'Neal<sup>1</sup>, S. Adhya<sup>2</sup>, A. Jenkins<sup>1</sup>, G. Ward<sup>1</sup>, J.B. Welsh<sup>2</sup>, G. Voskanyan<sup>2</sup>;  
<sup>1</sup>Department of Medicine, St Vincent's Hospital, University of Melbourne, Fitzroy, Australia, <sup>2</sup>Medtronic, Inc., Northridge, USA.

**Background and aims:** Subcutaneous insulin infusion and nearby glucose-sensing electrodes may interfere with each other. A new combination device, Combo-set, incorporates an insulin infusion catheter and a CGM sensor separated by a short distance. We evaluated insulin delivery and glucose sensing functions of this device.

**Materials and methods:** Ten adult subjects with type 1 diabetes participated in the 3-day study. Each subject had a Combo-set inserted in the abdomen, a contralateral Sof-sensor glucose sensor attached to an iPro recorder as a control, and a contralateral infusion set for routine insulin delivery. The Combo-set delivered insulin diluent except during meal tests on days 1 and 3, when boluses of insulin Lispro were delivered via the Combo-set. Post-bolus venous Lispro levels were determined at 0, 30, 60, 120, and 180 min.

**Results:** The Combo-set was well tolerated without any local skin reactions. The Combo-set sensor and control Sof-sensor had similar performance characteristics. The mean absolute relative difference (MARD) versus capillary blood glucose readings of the Combo-set sensor was similar to that of the Sof-sensor ( $p=0.63$ , NS). Clarke Error Grid analysis showed that 96.82% of

Combo-set values and 93.14% of Sof-sensor values were in the A+B regions ( $p=0.20$ , NS). Combo-set and Sof-sensor readings were comparably accurate during meal tests. Insulin via the Combo-set showed the expected post-bolus peak time ( $66.6\pm9.16$  min, mean  $\pm$  SE). The mean pre-bolus plasma insulin concentration was  $5.53\pm0.48$  mU/L and the mean post-bolus Cmax was  $52.47\pm6.09$  mU/L ( $N=17$ ). Postprandial glycemia with test meals was comparable to profiles obtained on Day 2, when subjects were on their usual diet and received insulin via the control infusion set. One "No Delivery" alarm occurred during the 21 patient-days of use, similar to the historical control rate of other infusion sets (1 per 24 patient-days in the CareLink database of 99,857 patients in 2010).

**Conclusion:** Comparable accuracy is found with glucose sensors placed near insulin infusion sites and glucose sensors placed elsewhere on the abdomen, and insulin pharmacokinetics and pharmacodynamics are unaffected by infusion catheter placement near glucose sensor insertion sites. This study shows the feasibility of simultaneous adjacent placement of an insulin infusion catheter and a CGM sensor.

## 1055

**Proposal for artificial pancreas device system-level mode logic design**

R. Kircher, R. Mauseth, D. Matheson;  
Dose Safety, Inc., Redmond, USA.

**Background and aims:** The Artificial Pancreas (AP) design continues to evolve due to advances in control algorithms, glucose sensor and insulin pump integration, and FDA guidance. This paper describes two proven strategies employed in the design the Boeing 777 Fly-By-Wire (FBW) Primary Flight Control System (PFCS) and applies those strategies to the Artificial Pancreas Device System (APDS). The main contribution of this abstract is a system specification rather than algorithmic realization.

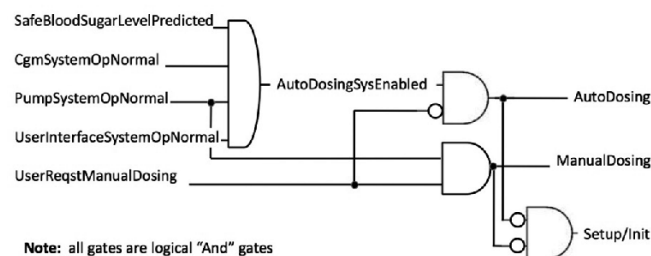

**Materials and methods:** Two design strategies of the 777 Primary Flight Control System (PFCS) are applicable to the APDS: 1) maintaining a flight control system operation that is consistent with a pilot's past training and experience, and 2) employing automated flight control mechanisms as the default while allowing the pilot to override those mechanisms on demand. This means that however different the actual flight control system architecture is from previous Boeing airplanes, the presentation to the pilot is that of a conventionally controlled mechanical system. The improved airplane handling quality and safety features are automatically provided without pilot action, yet the pilot may at any time bypass the advanced features and fly the airplane as if it had a mechanical system. The same design strategies may be applied to the APDS. For the APDS we propose design requirements that 1) preserve the user interface for the manual operation of the insulin pump and 2) enable the fully automated, closed loop control of blood sugar whenever it is safe to do so as shown on the figure. Automated dosing, the default mode, is enabled whenever: a) safe blood sugar levels are predicted; b) the CGM, pump and user interface subsystems are operating normally, and c) the user is not manually dosing. If neither manual dosing nor automated dosing is enabled, then the system goes to the Setup/Init mode. Results of simulated Use Cases and the resulting mode transition.

- 1) Predicted unsafe low blood sugar while in AutoDosing mode: Transition to ManualDosing
- 2) User infuses correction bolus while AutoDosing: Transition to ManualDosing
- 3) Predicted safe blood sugar after ManualDosing: Transition to AutoDosing
- 4) BG calibration needed while in AutoDosing mode: Remain in AutoDosing
- 5) Predicted safe blood sugar while CGM and pump operate normally in Init/Setup mode: Transition to AutoDosing
- 6) CGM sensor failure while in AutoDosing mode: Transition to ManualDosing + warning
- 7) Loss of comm. between AP device and CGM sensor while in AutoDosing: Transition to ManualDosing + warning

**Results:** The simulated execution of Use Cases utilizing the system-level APDS mode logic shows that the proposed top-level design meets the key requirements. The main contribution of this abstract is definition of high-level design requirements and a top-level APDS model logic design, based on the Boeing 777 FBW PFCS.

**Conclusion:** The 777 FBW Primary Flight Control System and the APDS have similar safety and user requirements. We believe that the proposed requirements and mode logic are suitable for APDS system development, regulatory approval, and commercialization.

### Proposed APDS Mode Logic

### Is there a diurnal pattern to insulin action in type 1 diabetes? Implications for a closed loop system

A. Basu<sup>1</sup>, D. Nandy<sup>1</sup>, C. Dalla Man<sup>2</sup>, A. Saad<sup>1</sup>, H. Ling<sup>1</sup>, J. Levine<sup>1</sup>, S. McCrady Spitzer<sup>1</sup>, R. Basu<sup>1</sup>, C. Cobelli<sup>2</sup>, Y. Kudva<sup>1</sup>;

<sup>1</sup>Endocrinology, Metabolism and Nutrition, Mayo Clinic College of Medicine, Rochester, USA, <sup>2</sup>Information Engineering, University of Padova, Italy.

**Background and aims:** We have recently demonstrated existence of a diurnal pattern to postprandial insulin action (Si) in individuals without diabetes with greater Si at breakfast than dinner. It is critical to determine the presence/absence of such a pattern in type 1 diabetes (T1D) to inform a cutting-edge closed loop control system.

**Materials and methods:** Individuals with c-peptide negative T1D (9 men, 7 women, BMI 25.4±1.0 kg/m<sup>2</sup>, age 41.9±3.7 yrs, fasting glucose 8.9±0.8 mM, HbA<sub>1c</sub> 7.2±0.2%) on CSII with normal gastric emptying determined by scintigraphy. Identical mixed meals (10 cal/kg, 50 g carbs; 35% carbs, 30% protein, 35% fat) containing [1-<sup>13</sup>C] glucose were ingested during either breakfast (B), lunch (L) or dinner (D) at 0700, 1300 and 1900 in randomised Latin Square order on three consecutive days. Physical activity measured with triaxial accelerometry was equal on all three days. During labeled meals, [6-<sup>3</sup>H] glucose and [6,6-<sup>2</sup>H<sub>2</sub>] glucose were infused to enable concurrent measurement of rates of meal appearance (MRa), endogenous glucose production (EGP), and glucose disappearance (Rd). Insulin was administered according to individualized insulin:carbohydrate ratio for each meal.

**Results:** Postprandial glucose excursions did not differ among meals [1424.6±235 (B) vs. 899.1±246 (L) vs. 997.0±295 (D) mM/6 hours; p=0.1]. However, postprandial insulin concentration was higher (p<0.03) at B than L but did not differ among other meals. There were no detectable differences in MRa, EGP and Rd between meals. In contrast, there was a trend (p=0.1) for a lower Si at B than D (5.81±2.3 vs. 11.21±3.3 10<sup>-4</sup> dl/kg/min per μU/ml) but did not differ from L (6.85±1.22 10<sup>-4</sup> dl/kg/min per μU/ml). 11/16 subjects demonstrated lower Si at B than D.

**Conclusion:** Under controlled experimental conditions when identical meals are consumed, insulin concentrations are higher at B and a trend noted towards lower Si at B than D. However, the inter-individual variance of Si patterns precludes uniform application to all people with T1D. The results suggest that although Si varies during the day, the pattern appears to be individual specific thus suggesting that Artificial Pancreas software systems may need to be personalised.

### Feasibility study assessing hypoglycaemia-hyperglycaemia minimiser (HHM) system in patients with type 1 diabetes in a clinical research centre (CRC)

L. Mackowiak<sup>1</sup>, D.A. Finan<sup>1</sup>, T.W. McCann<sup>1</sup>, R. Venugopalan<sup>1</sup>, H. Zisser<sup>2</sup>, H. Anhalt<sup>1</sup>;

<sup>1</sup>LifeScan, Inc., West Chester, <sup>2</sup>Sansum Diabetes Research Institute, Santa Barbara, USA.

**Background and aims:** A feasibility study was carried out in a CRC setting to assess the performance of a Hypoglycemia-Hyperglycemia Minimiser (HHM) System. This HHM System includes a continuous subcutaneous insulin infusion pump, continuous glucose monitor (CGM), and a model

predictive control algorithm with a safety module, and is run on a laptop platform.

**Materials and methods:** This study was a non-randomized, uncontrolled feasibility trial, at one CRC in the United States. The investigational system was studied for approximately 24 hours for each of 13 participants during periods of open- and closed-loop control. Insulin and food variables were adjusted to challenge and assess the system. The primary objective was to evaluate the ability of the control algorithm to predict a rise or fall in glucose above or below set thresholds, and to command the pump to increase, decrease, suspend, or resume insulin infusion accordingly. The secondary objectives were to understand the HHM System's ability to safely keep glucose levels within a target range, and to provide guidance in future development.

**Results:** The study population included 13 participants; age 24-57 years; female n = 11; BMI mean (SD) 24.7 kg/m<sup>2</sup> (5.1); duration of T1DM mean (SD) 27.2 years (13.3); HbA<sub>1c</sub> mean (SD) 7.4% (0.8). The HHM System was able to predict a rise and fall in CGM glucose, and to adjust insulin accordingly in an attempt to minimize glucose excursions. The system provided warnings in advance of significant decreases in CGM glucose. There were no safety concerns, including no diabetic ketoacidosis (DKA) or severe hypoglycemia.

**Conclusion:** In conclusion, the primary and secondary objectives of this feasibility study were met, showing that, including during periods of adjustment of food and insulin variables, the HHM System was able to respond in an attempt to keep glucose levels within a specified target range by varying insulin infusion rates based on closed-loop CGM levels. Planning for further studies is underway.

Closed-loop timeframe	Time spent < 3.8 mmol/L (70 mg/dL) by CGM
Overnight (12am - 7am)	0.1%
Post breakfast (7am - 1pm)	1.5%
Post lunch (1pm - 8pm)	0.0%
Overall	0.5%

Clinical Trial Registration Number: NCT01401751

### Sensor-augmented pump therapy in real-life: patients reported outcomes results of the INTERPRET observational study

K. Nørgaard<sup>1</sup>, A. Scaramuzza<sup>2</sup>, N. Bratina<sup>3</sup>, N. Lalić<sup>4</sup>, P. Jarosz-Chobot<sup>5</sup>, G. Kocsis<sup>6</sup>, R. Verkauskienė<sup>7</sup>, C. De Block<sup>8</sup>, O. Carrette<sup>9</sup>, S. de Portu<sup>9</sup>, J. Castañeda<sup>10</sup>, O. Cohen<sup>11</sup>, the INTERPRET study group;

<sup>1</sup>Department of Endocrinology 541, Hvidovre University Hospital, Denmark, <sup>2</sup>Luigi Sacco Hospital, Milan, Italy, <sup>3</sup>UMC-University Children's Hospital, Ljubljana, Slovenia, <sup>4</sup>Clinic for Endocrinology CCS, Belgrade, Serbia, <sup>5</sup>Specjalistyczna Praktyka Lekarska, Gliwice, Poland, <sup>6</sup>Péterfy Hospital, Budapest, Hungary, <sup>7</sup>Kaunas University Children Hospital, Lithuania, <sup>8</sup>Antwerp University Hospital, Belgium, <sup>9</sup>Medtronic International Trading Sàrl, Tolochenaz, Switzerland, <sup>10</sup>Medtronic Bakken Research Center, Maastricht, Netherlands, <sup>11</sup>Chaim Sheba Medical Center, Tel Hashomer, Israel.

**Background and aims:** Subjective factors are important for people with diabetes because the disease is primarily self-managed and self-management regimens affect virtually all aspects of daily life. The aim of the study was to evaluate, in real life setting, the impact of Continuous Glucose Monitoring (CGM) on patients reported outcomes.

**Materials and methods:** INTERPRET is a prospective multi-centre observational study, enrolling children and adults with type 1 diabetes (T1DM) who are adding CGM to insulin pump therapy (CSII) after more than 6 months on CSII. Sensors are expected to be used at least 10% of the time during one year. Diabetes Treatment Satisfaction Questionnaire status and change versions (DTSQs and DTSQc) and Fear of Hypoglycemia (HFS) questionnaires were collected at baseline and at 12 months.

**Results:** 263 T1DM patients (mean age: 28.0 ± 15.7 years; diabetes duration: 13.9 ± 10.7 years; CSII duration: 2.6 ± 3 years and sensor usage: 30%) were eligible. After one year follow-up treatment satisfaction remained unchanged with high positive scores (32 out of 36). CGM was associated with a significant decrease in the perceived frequency of hyperglycemic episodes (p=0.047). DTSQc questionnaire, with all patients reporting positive score at 12 months follow up, is indicating an improvement in treatment satisfaction compared with previous treatment; the perceived frequency of hyperglycemia

as and hypoglycemia was also reduced with CGM. Total HFS score was significantly improved versus baseline after 12 months of treatment (37.00 vs 28.95, -6.9 adjusted decrease,  $p=0.003$ ) and both, behaviors to avoid hypoglycemia and worries about hypoglycemia, subscales were significantly improved over the 12 months of treatment with CGM (16.03 vs 13.35, -2.6 adjusted decrease,  $p=0.024$  and, 23.39 vs 18.40, -4.1 adjusted decrease,  $p=0.003$ , respectively).

**Conclusion:** This is the largest and longest international observational study providing real-life data on Sensor Augmented Pump. This study indicates that CGM led to a significant decrease in patient's fear of hypoglycemia and provides additional evidence on the positive impact of CGM on patient's treatment satisfaction.

## 1059

### Use of predictive alerts in the Revel insulin pump

F.R. Kaufman, P. Agrawal, J.B. Welsh, B. Kannard;  
Medtronic, Inc., Northridge, USA.

**Background and aims:** The Revel sensor-augmented insulin pump allows for setting high and low predictive alerts at threshold sensor glucose values between 40 and 400 mg/dL, with predictive horizons from 5 to 30 min. We analyzed CareLink data to understand typical alert settings and how patients respond following alert activations.

**Materials and methods:** Data from 3642 Revel insulin pump users with predictive alerts activated during the month of January, 2012 were found in the CareLink database. There were a total of 72,153 patient-days analyzed.

**Results:** The mean (SD) setting for the low glucose alert was 79.83 (14.49) mg/dL (4.44 [0.80] mM) and the mean time of the predictive horizon was 19.17 (6.60) min. The mean setting for the high glucose alert was 224.09 (50.60) mg/dL (12.45 [2.81] mM) and the mean time of the predictive horizon was 19.87 (7.30) min. There were 161,486 low predictive alerts (2.24 per patient-day) and 84,016 high predictive alerts (1.16 per patient-day). The Table shows the cumulative occurrence of various actions taken 10, 30 and 60 minutes after low and high predictive alerts were activated. Low alerts occurred much more frequently than high alerts, but the predictive time horizons for low and high alerts were very similar. Approximately a third of subjects obtained a fingerstick glucose value within 60 min of an alert. Carbohydrate ingestion is likely underestimated in this analysis since most subjects may not enter this into the Bolus Wizard (BW) estimation algorithm. Very few subjects initiated temporary changes to their insulin infusion rates or suspended insulin in response to low glucose alerts. By 60 min, close to half of subjects had taken a bolus of insulin in response to high glucose alerts. Use of the predictive alert feature was associated with a significantly lower percentage of SG values <50 mg/dL whether the threshold alert setting was on (0.54% vs. 0.58%, respectively,  $p<0.001$ ) or off (1.03% vs. 1.44%, respectively,  $p<0.02$ ).

**Conclusion:** Revel pump patients who use predictive alerts experience frequent alert activations, many of which lead to behaviors designed to minimize hyperglycemia and hypoglycemia. Use of the predictive alert may reduce the time spent in hypoglycemia.

Table. Actions following low and high predictive alerts

After low alert	10 min	30 min	60 min
BG meter reading	14369 (8.90%)	32722 (20.26%)	52550 (32.54%)
BW carb entry	4620 (2.86%)	13429 (8.32%)	26230 (16.24%)
Suspend insulin	2435 (1.51%)	4605 (2.85%)	6692 (4.14%)
Temp basal rate	2496 (1.55%)	4300 (2.66%)	5911 (3.66%)
After high alert	10 min	30 min	60 min
BG meter reading	9806 (11.67%)	18131 (21.58%)	26346 (31.36%)
Bolus given	19797 (23.56%)	30711 (36.55%)	38824 (46.21%)
Temp basal rate	779 (0.93%)	1298 (1.54%)	1852 (2.20%)

Cumulative occurrence (N, %) of activities and pump interactions following 161,486 low predictive alerts (upper rows) and 84,016 high predictive alerts (lower rows).

## 1060

### Clinical evaluation of a fully-automated artificial pancreas using zone-model predictive control with health monitoring system

H.C. Zisser<sup>1</sup>, E. Dassau<sup>2</sup>, R. Harvey<sup>2</sup>, W. Bevier<sup>1</sup>, L. Jovanovic<sup>1</sup>, F.J. Doyle III<sup>2</sup>;  
<sup>1</sup>Clinical Research, Sansum Diabetes Research Institute, <sup>2</sup>Chemical Engineering, University of California Santa Barbara, Santa Barbara, USA.

We evaluated a fully automated closed-loop artificial pancreas in 12 subjects (8F:4M) with type 1 diabetes (age mean $\pm$ SD 49.4 $\pm$ 10.4, diabetes duration 32.7 $\pm$ 16.0y, A1C 7.3 $\pm$ 1.2). Subjects were studied in-clinic for 25 hours. One day prior to the session, two continuous glucose sensors (DexCom, San Diego) were inserted. CGM values were used as the input of the system. Subjects arrived at 4PM, their insulin pump was discontinued and a study CSII pump (Animas, West Chester, PA) was inserted. Plasma glucose was measured every 30 min by YSI for safety. The subjects ate 2 mixed meals (50 gm CHO dinner/40 gm CHO breakfast) and underwent a 30 min exercise session at 50% of the predicted heart rate reserve at 11:30 AM. There were no meal announcements or pre-meal boli. Subjects were discharged at 6PM on the following day. A zone-model predictive controller was used to control glucose concentration. The controller used an a priori model that was initialized with the subject's total daily insulin. The controller was designed to keep the glucose between 70-180mg/dl during the day and 80-140mg/dl overnight. A predictive hypoglycemia prevention algorithm (Health Monitoring System/HMS) designed to alarm if the glucose was predicted to cross 70 mg/dl in the next 15 min was used in conjunction with the zone controller to minimize the risk of hypoglycemia. The subject was given 16 gm CHO if the HMS alarm was triggered. Time in range (YSI 70-180 mg/dl): Entire session = 81%, 12AM to 7AM = 92%, session minus postprandial/exercise periods = 92%. Time in range 80-140 mg/dl: 12 AM to 7 AM = 70%. Time spent < 70 mg/dl for entire session by YSI = 1%. During the overnight period, there were no YSI values below 70 mg/dl. There were no safety events. The HMS sent appropriate warnings to prevent hypoglycemia via SMS & MMS. The combination of the zone-MPC controller and the HMS hypoglycemia prevention algorithm was able to safely regulate glucose, including challenges of unannounced meals and moderate of exercise.

*Clinical Trial Registration Number: NCT01472406*

*Supported by: NIH*

## PS 090 Predicting pregnancy outcomes

1061

### Obstetric and perinatal outcomes in diabetic women submitted to assisted reproduction techniques

E. Moreno, S. Costa, D. Acosta, N. García, L. Cerrillos, R. Torrejón;  
Virgen del Rocio Hospital, Sevilla, Spain.

**Objectives:** To evaluate the obstetric and neonatal outcomes in pregnancies in women PGDM or GDM submitted to ART, followed between January 1, 2004 and June 30, 2010.

**Materials and methods:** We included 120 women undergoing ART (Artificial Insemination (AI) or Embryo with Transfer (IVF or IVF-ET)) with PGDM or GDM. We performed a prospective observational study analyzing age, height and weight at the beginning of pregnancy, final weight, parity, type of diabetes, type of ART, concomitant diseases, degree of metabolic control, termination of pregnancy and children's hospital admission. In each patient group also analyzed the following variables: multiple pregnancy, pathology of the first trimester, percentage of preterm births, number of induced labor, mode of delivery, cesarean section rate and reasons for such, frequency of fetal macrosomia (>4000 grams), revenues in the Neonatal Intensive Care Unit (NICU), congenital malformations, and perinatal mortality.

**Results:** We studied 120 women with age of  $35.21 \pm 4.1$  years. 97 undergoing IVF, 14 to AI, 1 to AI with donor sperm and 8 oviducts. There were 30 women with PGDM and 90 with GDM. Of all pregnancies, 66% were singleton pregnancies, 32% dichorionic twin pregnancies biamniotic, 1% monochorionic twins, and 2% trigemellar. There was 1 case of embryonal reduction. There was 3 cases of abortion: all in women undergoing IVF-ET with PGDM. The rate of prematurity was 31%, 3% of very preterm and 28% between weeks 34 and 37. Among the cases of big preterm: 1 was to 29 weeks in a mother with DM1, who developed hypertension (HT), weight of newborn (NB) was 910 g and died on day 7 of life from sepsis; the second case was at 32 weeks for premature rupture of membranes, born a woman of 1610 gr, with favorable evolution; the third case was a very preterm in diamniotic dichorionic twin gestation that ended in cesarean section at 32 weeks and 4 days for preeclampsia and breech presentation of the first fetus. 54 (45%) pregnancies ended in caesarean section, 14 births eutocic (12%). We need to use vacuum in 10 cases (8%), 1 case with spatulas and forceps in 6 cases (5%). There were 9 twin births (8%). There were also 23 cases of extraclinical births, of which we have no information. The most frequently causes of cesarean were failure of induction by 20%, pelvic-cephalic disproportion in 15%, and twin pregnancy by 13%. Data regarding neonatal birth weight was as follows: 1% <1499 g, 6% between 1500 to 2499 g, 47% between 2500 to 3499 g, 29% between 3500 to 3999 g, 5%  $\geq 4000$  g and 12% with unknown data. 23 newborn (19%) required admission to the NICU: 6 for low birth weight, 1 for intrauterine growth retardation, 5 hypoglycemia, 5 of prematurity, 2 for distress, 2 for neonatal jaundice, 1 for suspected coarctation aortic and 1 caudal regression syndrome. About perinatal morbidity and mortality we observed 1 Down syndrome, 1 case of fracture clavicle, 1 postnatal death from sepsis in a very premature, 1 anal malformation, 1 coarctation of the aorta, 1 caudal regression syndrome and 1 facial asymmetry in a macrosoma fetus of 4100g, all cases in women with PGDM.

**Conclusion:** The obstetric and neonatal morbidity observed in women with PGDM undergoing ART is high, clearly related to the degree of metabolic control at the time of conception and the coexistence of visceral complications related to diabetes and / or overweight-obesity. Perinatal and neonatal loss date has been a frequent problem, and a better programming of pregnancy's a important area for improvement in care for this condition.

1062

### Gestational age at delivery in diabetic patients depending on the initial level of daily urinary albumin excretion, arterial hypertension and method of insulin injection

Z.R. Alimetova<sup>1</sup>, F.V. Valeeva<sup>1</sup>, T.N. Akhmetzianova<sup>1</sup>, I.R. Galimova<sup>2</sup>;

<sup>1</sup> Hospital therapy, Kazan State Medical University, <sup>2</sup> Republic Clinical Hospital, Kazan, Russian Federation.

**Background and aims:** Evaluate the delivery time in patients with diabetes mellitus type 1 (DM) depending on the initial level of daily urinary albumin excretion, arterial hypertension and method of insulin injections.

**Materials and methods:** Pregnancy outcomes were analyzed in 56 patients with DM 1 at the age of 19 to 37 years [26 (23, 29)] years, duration of DM of 1 month to 20 years [9 (2.8, 12.5) years]. The average level of HbA1c was 6.0 (5.4, 6.9)%. Depending on the initial stage DN all pregnant women were divided into 2 groups: those with baseline severe kidney disease (proteinuric stage) (15 women) and without the DN or the initial stage DN (normal and microalbuminuria) (41 women). 26 patients received insulin in the regime of multiple subcutaneous injections of insulin (MSII), 30 pregnant women - in the mode of constant subcutaneous insulin infusion (CSII).

**Results:** In severe DN 15 women early, the median period of delivery was 34.0 (32.5, 34.5). In the second group of women with the lack of severe manifestations of the DN were 28 women out of 41 (68.3%) delivered within a median time of delivery 38 (37.3, 39.0) weeks. Preterm delivery in this group - 13 women (31.7%) was associated with the growth of the severity of preeclampsia, with a gestational age at delivery in the group of patients with no severe renal disease of 35.5 (35.0, 37.0) w., which was higher than in the group with baseline severe renal disease ( $p = 0.005$ ). In the group of pregnant women with DM 1 with AH (19 women) the pregnancy was completed earlier - 34.0 (33.0, 35.0) weeks than in the group of pregnant women with DM 1 without AH (37) - 38.0 (37.0, 39.0) w. ( $p < 0.001$ ). In the group with AH 79.0% (15) were patients with initial proteinuric stage of DN, 21.0% (4 women) - with the initial lack of, or the initial phase of DN, in the case of severe DN the pregnancy was completed on 34.0 (32.5, 34.0) w., without or the initial stage of DN - 35.5 (34.8, 36.0) w. ( $p = 0.05$ ). In the group of women with DM 1 without AH in all patients (37 women) were absent of DN or NAM initial manifestations. However, even with the same daily urinary albumin excretion in the presence of AH pregnancy was completed significantly earlier ( $p = 0.004$ ). In the group of patients without AH on the CSII delivery was on the 38.5 (38.0, 39.0) w., using MSII pregnancy was completed earlier - 38.0 (37.0, 38.0) ( $p = 0.01$ ). In the group with the initial absence or in the initial stage of DN on CSII carried pregnancy to term 38-40 w. 86.4% (19 patients), premature delivery was used in 13.6% (3 women). In a similar group at MSII carried pregnancy to term 38-40 w. were 47.4% (9 patients), early delivery in 52.6% (10 women), which is significantly different from the results of the use of CSII ( $p = 0.02$ ). In case of early termination of pregnancy in the group of patients on CSII (3 patients) median time of delivery was 36.0 (36.0, 36.5) w., using MSII - 35.5 (35.0, 37.0) w. ( $p = 0.54$ ). The median date of completion of pregnancy in patients with initially severe DN was 34.0 (33.0, 34.0) w. in a group at MSII - 34.0 (30.5, 34.5) w. ( $p > 0.05$ ). In the presence of AH on CSII pregnancy is completed at the 34.0 (33.5, 36.0) weeks, at MSII - 34.0 (32.5, 34.8) w. ( $p = 0.67$ ).

**Conclusion:** Gestational age at delivery in patients with type 1 diabetes with severe baseline DN and the presence of hypertension decreased from 38 to 32-34 weeks. CSII compared with MSII can prolong pregnancy in patients with type 1 diabetes.

1063

### Does the presence of thyroid antibodies affect the course and outcome of pregnancy in type 1 diabetic women?

V. Vasileiou, V. Sarantopoulou, G. Philippou, P. Lymberi, L. Sarika, M. Alevizaki, E. Anastasiou;

1st Endocrine Section- Diabetes Center, Alexandra Hospital, Athens, Greece.

**Introduction:** In the literature there are only three papers so far, addressing the impact of thyroid antibodies (Anti-TPO) on pregnancy in Type1 Diabetic Women (DM1) and these present conflicting results. The aim of the study is to evaluate the presence of Anti-TPO in DM1 pregnant women and whether these are related with differences in thyroid function, metabolic control and pregnancy outcome.

**Methods:** In 78 DM1 women with singleton pregnancies Anti-TPO, Anti-Tg, TSH, FT4I (T4/TBC) were measured each trimester. At each visit (every 1-2 weeks) blood glucose, HbA1c, BMI, units of insulin/Kg were recorded, as were complications and pregnancy outcome.

**Results:** 27/78 women (34.6%) presented with positive Anti-TPO Abs. Clinical data of Anti-TPO positive and negative women are as shown in the table. First trimester TSH levels were statistically different between the two groups. There were no differences in the prevalence of diabetic complications, gestational hypertension-preeclampsia, abortions or preterm deliveries.

**Conclusion:** One third of DM1 pregnant women presented with positive Anti-TPO Abs. However their presence is not related with worse metabolic control or adverse pregnancy outcome. It seems that early treatment of thyroid dysfunction and stricter metabolic control plays a more important role than the presence of thyroid antibodies with regard to the pregnancy outcome.

## 1064

### Pre-pregnancy and first trimester glycaemic control determines foetal and maternal outcomes in women with type 1 and type 2 diabetes

E. Mustafa, S. Khalil, B. Kirwan, L. Carmody, T. Gallcher, M. Todd, M. Durkan, S. Hoashi, F. Dunne;  
Department of Medicine, College of Medicine, Nursing and Health Sciences, Galway, Ireland.

**Background and aims:** Pre gestational diabetes during pregnancy poses a significant adverse impact on maternal and neonatal outcomes. A structured Pre Pregnancy Care (PPC) programme aiming to achieve optimal glycaemic control in the preconception period, increase use of folic acid, screen and stabilise diabetes complications and alteration of teratogenic medications can decrease perinatal morbidity and mortality and improve maternal morbidity. As part of our ATLANTIC DIP program we are undertaking a single arm prospective study to compare foetal and maternal outcomes in women who attend (Attendees) PPC to those who decline an invitation to attend (Non-attendees).

**Materials and methods:** To date we have identified 551 women of child bearing age with Type 1 and Type 2 Diabetes. They were invited to participate in the programme at one of 4 regional PPC clinics in the region. Consented patients received a multidisciplinary care package with pregnancy specific education on glycaemic targets hypoglycaemia and dietary advice. They had a review of medications and complications and commenced on folic acid. Pregnancies were followed to term and data on maternal and infant outcomes and glycaemic control were collected via DIAMOND.

**Results:** Of the 551 women identified 162 women (30%) have consented and attended (Attendees). 90 women (59%) had Type1 and 72 patients (41%) Type 2 diabetes. There have been 102 confirmed pregnancies in Attendees. 37 women declined to attend for PPC (Non Attendees) and 37 pregnancies have been confirmed in this group. The latter group were older (33.8 v 31.3 years) than Attendees (P= 0.005) but there was no difference in duration of disease between the groups. All Attendees received folic acid (100%) and their mean HbA<sub>1c</sub> was 6.6% (5.2-8.5) prior to conception, and 6.6% (4.6%-7.8%) in the first trimester with 78% achieving a HbA<sub>1c</sub> <7% at conception. By contrast the mean first trimester HbA<sub>1c</sub> was 8% (4.8-11.7) in Non Attendees with only 38% achieving a HbA<sub>1c</sub> <7% at conception and 29% receiving folic acid (P =0.005). There was no difference in HbA<sub>1c</sub> in the second or third trimesters between the two groups (P= 0.72 and 0.07 respectively). Composite foetal morbidity (hypoglycemia, jaundice, respiratory distress and polycythemia) was significantly less in Attendees compared to Non - Attendees (P=0.04). Admission to the Neonatal Unit (NNU) was significantly higher in Non-Attendees (84%) compared to Attendees (40%) (P <0.005). There were 2 cases of intrauterine fetal death < 24 weeks (IUID) one of them in a twin pregnancy in Attendees compared to 1 case of stillbirth at 37 weeks in Non-Attendees. No congenital anomalies were seen in Attendees compared to 2 cases in Non-Attendees. There was no difference in maternal morbidities (Pre-eclampsia, Pregnancy induced hypertension, Ant partum and

postpartum haemorrhage) between the groups (P= 0.35) or in Caesarean section rates (64% v 63%).

**Conclusion:** PPC achieving better preconception and early pregnancy glycaemic control and increased folic acid uptake in Attendees is translated into a decrease in fetal mortality and morbidities resulting in an increased take home baby rate. In addition the need for admissions to NNU care was significantly reduced resulting in cost benefits. The uptake rate to PPC remains low and requires further investigation through focus groups and proposed use of social networking.

## 1065

### Evaluation of 1,5-anhydroglucitol as marker of glycaemic control and birth weight in pregnancy complicated by type 1 diabetes mellitus

N. Nowak<sup>1</sup>, K. Cyganek<sup>1,2</sup>, B. Matejko<sup>1</sup>, M.T. Malecki<sup>1,2</sup>;

<sup>1</sup>Department of Metabolic Diseases, Jagiellonian University, <sup>2</sup>University Hospital, Krakow, Poland.

**Background and aims:** 1,5-anhydroglucitol (1,5-AG) is a marker of short-term glycemic control in diabetes - it reflects the period of the last 1-2 weeks. Its excretion rate depends on the renal glucose threshold, which is decreased during pregnancy. Thus, it is not clear whether it may be used in pregnant women with diabetes mellitus. We tested pregnant patients with type 1 diabetes mellitus (T1DM) to answer a) what is the relationship between 1,5-AG level and glycemic control assessed by continuous glucose monitoring (CGM); b) whether this particle is a predictor of birth weight.

**Materials and methods:** We examined 82 pregnant women with T1DM (mean age: 29.7 years; SD=4.5, mean diabetes duration: 12.7 yrs; SD=7.4). In each trimester, 1,5-AG concentration was measured with an immunoenzymatic assay. The data from CGM device were collected in 58 pregnancies for a 7-day period before blood collection for 1,5-AG and HbA<sub>1c</sub> analysis. The data were analyzed with Pearson correlation coefficients and multivariate regression. Receiver operating characteristic (ROC) curve analysis was used to evaluate third-trimester 1,5-AG level as a predictor of macrosomia (defined as birth weight of 4000g or more) and large for gestational age (LGA) birth weight (≥90th percentile).

**Results:** 1,5-AG correlated significantly with glycemic indices recorded by CGM: area under the curve at 140 mg/dl (r=-0.66, p=1x10<sup>-7</sup>), average maximal glucose (r=-0.58, p=4x10<sup>-6</sup>), glucose standard deviation (r=-0.6, p=2x10<sup>-6</sup>) and mean glucose (r=-0.54, p=3.1x10<sup>-5</sup>). In multivariate linear regression, 1,5-AG was independently associated with the newborn's weight (p<1x10<sup>-6</sup>), this remained highly significant also after the incorporation of HbA<sub>1c</sub> into the model (p<1x10<sup>-6</sup>). In multivariate logistic regression, low 1,5-AG concentration significantly predicted LGA (OR: 0.35, 95% CI:0.17-0.68, p=0.0025) and macrosomia (OR: 0.18, 95% CI:0.06-0.55, p=0.0024). The area under the 1,5-AG ROC curve in the LGA prediction was 0.81 (95% CI:0.7-0.89) at a criterion of 4.75 μg/ml. The AUC in the prediction of macrosomia was 0.84 (95% CI:0.75-0.93) at 4.27 μg/ml of serum 1,5-AG.

**Conclusion:** 1,5-AG is an accurate indicator of glycemic control as assessed by CGM in pregnant women with T1DM. In addition, its level in the 3rd trimester could be prognostic for birth weight. Thus, 1,5-AG use in glycemic control monitoring as well as neonatal macrosomia and LGA prediction should be considered in this population.

## 1066

### The association of metabolic parameters with BMI and insulin resistance in young children beyond maternal hyperglycaemia during pregnancy

L. Bozkurt, C.S. Göbl, B. Rami, A. Luger, E. Schober, A. Kautzky-Willer;  
Medical University of Vienna, Austria.

**Background and aims:** Early experience of elevated insulin concentration during critical periods of perinatal development might contribute to a lasting malprogramming of endocrine systems regulating body weight and metabolism. The aim was to assess associations in BMI-SDS (standard-deviation-score) and IR (insulin resistance) with regulating hormones in young children of mothers affected by different types of diabetes during pregnancy.

**Materials and methods:** In a prospective study, 76 children aged 4-9 years were included for clinical examinations comprising anthropometric assessments and a fasting venous blood sample for metabolic measurements including determination of leptin, ghrelin and GDF-15. Three groups were

formed according to the diabetic status of the mother during pregnancy, i.e. pre-existing diabetes, gestational diabetes and normal glucose tolerance (NGT).

**Results:** We found significant correlations between BMI-SDS and leptin ( $r=0.61$ ,  $p<0.001$ ), ghrelin ( $r=-0.32$ ,  $p=0.005$ ), usCRP ( $r=0.48$ ,  $p<0.001$ ) and HOMA ( $r=0.36$ ,  $p=0.002$ ) in the total population. Further, level of IR as determined by HOMA was associated with leptin ( $r=0.37$ ,  $p=0.001$ ), ghrelin ( $r=-0.30$ ,  $p=0.01$ ), GDF-15 ( $r=-0.38$ ,  $p=0.001$ ) as well as BMI-SDS ( $r=0.36$ ,  $p=0.002$ ) in univariable analysis. The association of GDF-15, BMI-SDS and leptin with IR was shown to be independent by using a multiple linear regression explaining 38% of the variance. Group based analysis revealed that observed correlations depended on maternal type of diabetes; with exception of leptin to BMI, no other association occurred in NGT-children.

**Conclusion:** Our results showed an inverse correlation of GDF-15 to IR in young children exposed to diabetes in utero. This association was independent of BMI-SDS and leptin. Further studies are at need to clarify the role of GDF-15 in the development of IR.

### Insulin pump is effective to reduce macrosomia in pregnancies complicated by type 1 diabetes

F. Lorenzini<sup>1</sup>, B. Guyard Boileau<sup>1</sup>, V. Melki<sup>2</sup>, H. Hanaire<sup>2</sup>;

<sup>1</sup>Hopital Paule de Viguier, <sup>2</sup>Hopital Rangueil, CHU Toulouse, Toulouse, France.

**Background and aims:** Insulin pump is widely used during diabetic pregnancies, despite lack of randomized studies. We decided to report our “every-day life experience” with pump (CSII) in type 1, compared with rapids analogs multiple daily injections (MDI) treatment.

**Materials and methods:** Retrospective analysis of 98 type 1 patients, successfully managed in our tertiary care center, by a multidisciplinary team. 3 groups are described: G1 n=55 treated with pump before pregnancy (6 months to 12 years), G2 n=25, in whom pumps began during pregnancy (6 to 36 Weeks), and G3 n=18 remained on MDI.

**Results:** Diabetes is older and more complicated in G1 ( $p<0,03$ ), with more hypertension, retinopathy nephropathy, and laser treatment. HbA1c is better in G1 vs G2 and G3 at conception (6,79, 7,65 and 7,5%  $p<0,003$ ) and throughout pregnancy (second trimester: 5,91, 6,27, 6,51  $p=0,003$ ), to delivery (5,97, 6,38, 6,32  $p=0,03$ ). No differences in term (37,3WA), birthweight (3231/3201/3310g). But there is significantly less macrosomia in pump groups (16,4 vs 20 and 30%  $p<0,05$ ), suggesting best control with CSII in late pregnancy. Insulin doses tend to be smaller in G1 (1U/Kg vs 1,2 and 1,3) No keto acidosis, 3 episodes of ketosis in G2, none in other groups. Frequency of severe hypoglycemia, related to diabetes duration, is not different in 3 groups.

**Conclusion:** Insulin pump is effective in diabetic pregnancy, especially in older and severe diabetes to reduce HbA1c and macrosomia, without side effects when started before conception.

### Glycaemic control and weight gain in post-pregnancy follow-up of type 1 diabetic women

K. Cyganek<sup>1</sup>, A. Hebda-Szydło<sup>1</sup>, J. Skupien<sup>2</sup>, I. Janas<sup>1</sup>, J. Walczyk<sup>1</sup>, S. Borys<sup>1</sup>, A. Lipowska<sup>3</sup>, M. Szopa<sup>1</sup>, M.T. Malecki<sup>4</sup>;

<sup>1</sup>Department of Metabolic Disease, University Hospital, Krakow, Poland,

<sup>2</sup>Section on Genetics and Epidemiology, Joslin Diabetes Center, Boston, USA, <sup>3</sup>Emory University School of Medicine, Atlanta, USA, <sup>4</sup>Department of Metabolic Disease, Jagiellonian University, Krakow, Poland.

**Background and aims:** Glycaemic control during pregnancy complicated by type 1 diabetes mellitus (T1DM) is essential for clinical outcomes. It is well-documented that most pregnant T1DM women achieve normoglycemia; however, intensive diabetes management is associated with weight gain. There is scarce data on glycaemic control and weight change after the delivery. We aimed to examine post-pregnancy glycaemic control and weight changes in T1DM women.

**Materials and methods:** We analysed 378 singleton pregnancies in T1DM women receiving medical care at Department of Metabolic Diseases, Krakow, Poland. We identified 274 subjects that participated in an intensive diabetes

management program and had at least two follow-up visits after the delivery with HbA<sub>1c</sub> and weight measurements.

**Results:** The study subjects mean age was 27.8 years  $\pm 5.0$ , with diabetes duration of 11.6 years  $\pm 7.4$ . The mean initial HbA<sub>1c</sub> level during pregnancy was 7.0%  $\pm 1.5$ , while pre-pregnancy weight was 64.5 kg  $\pm 1.5$ , BMI 23.8  $\pm 3.2$  kg/m<sup>2</sup>. The mean HbA<sub>1c</sub> in the 3rd trimester was 5.7%  $\pm 1.0$ . We observed a mean gestational weight gain of 14.2 kg  $\pm 1.5$ . During the first 6 months after delivery, HbA<sub>1c</sub> increased by 0.9% ( $p<0.0001$ ), while weight increased by 4.7 kg compared to the pre-pregnancy weight ( $p<0.0001$ ) and BMI increased to 25.5 ( $p<0.0001$ ) compared to the pre-gestational BMI. After another 6 months, HbA<sub>1c</sub> further deteriorated by 0.3%, surpassing the HbA<sub>1c</sub> value during the last trimester ( $p<0.0001$ ). The last HbA<sub>1c</sub> recorded (more than 12 months after delivery) was 1.5% higher than during pregnancy ( $p<0.0001$ ) and not different from the pre-gestational HbA<sub>1c</sub> (7.2% vs. 7.2%,  $p=0.9$ ). The weight and BMI did not return to the pre-pregnancy level, weight was 2.5 kg and BMI 1 kg/m<sup>2</sup> higher ( $p<0.0001$ ).

**Conclusion:** In summary, in this large clinical observation, T1DM women showed substantial post-pregnancy deterioration in glycaemic control. They were also unable to return to their pre-pregnancy weight. We suggest that T1DM women require special medical care after delivery to maintain their glycemic control and weight within the therapeutic targets.

## 1069

### Pregnancy in type 2 diabetes - sub-optimal outcomes despite optimal glycaemic control

L.A. Owens<sup>1</sup>, G. Avalos<sup>1</sup>, L. Carmody<sup>2</sup>, B. Kirwan<sup>2</sup>, F. Dunne<sup>1</sup>;

<sup>1</sup>Department of Medicine, <sup>2</sup>Department of Nursing and Health Sciences, National University of Ireland, Galway, Ireland.

**Background and aims:** Pregnancy in women with Type 2 Diabetes is associated with higher maternal and neonatal morbidity and mortality. Given the rising incidence of this condition worldwide, optimisation of clinical care is important and has been shown to improve pregnancy outcomes. This retrospective study aims to compare pregnancy outcomes in women with type 2 diabetes (T2DM) with women who are screen negative for gestational diabetes (GDM).

**Materials and methods:** The Atlantic Diabetes in Pregnancy programme (ATLANTIC DIP) aims to provide optimal care for women with diabetes before, during and after pregnancy. We now compare the demographics and pregnancy outcomes of women with known Type 2 diabetes with those who have been shown to have normal glucose tolerance (NGT) through a universal screening programme for GDM. Testing for GDM occurred between 24–28 weeks gestation and consisted of 75g 2 hour oral glucose tolerance testing using IADPSG guidelines.

**Results:** 105 women with T2DM and 105 age-matched women with NGT were included. Mean age was 33.8 years. 18% of women with T2DM had pre-pregnancy care (PPC) and half (50%) took folic acid prior to conception. These women had a mean HbA1c of 48mmol (6.5%) at their first antenatal or booking visit. Only 9% of women with Type 2 Diabetes had an HbA1c of above 53mmol (7%) at any stage during pregnancy. 71% were treated with insulin. There were more non-Caucasian women with Type 2 Diabetes than in the NGT group (31.4% vs 3.9%,  $p<0.0001$ ). Women with Type 2 diabetes were heavier, with a mean BMI of 32.9 ( $\pm 6.4$ ) kg/m<sup>2</sup> compared to 26.9 ( $\pm 3.9$ ) kg/m in the NGT group ( $P = .$ ). 43% of women with Type 2 diabetes reported a previous miscarriage, significantly higher than women with NGT (24%,  $p=0.005$ ), and 25% had a hypertensive disorder in pregnancy compared to 10% in the NGT group ( $p=0.004$ ). 61% of women delivered by caesarean section compared to 24% in the NGT group ( $p<0.0001$ ), 40% of which were considered ‘emergent’. 52% of babies from mothers with Type 2 Diabetes required care in the neonatal intensive care unit after delivery compared to 9.6% of babies born to mothers with NGT ( $p<0.0001$ ). Overall fetal outcomes were worse in pregnancies complicated by diabetes, with an 86.5% live birth rate compared to 99% in women with NGT ( $p<0.0001$ ). There was a non-significant trend towards more congenital malformations in women with diabetes ( $p=0.16$ ). Rates of macrosomia and shoulder dystocia were not higher in the group with diabetes.

**Conclusion:** Despite good glycaemic control, pregnancy outcomes remain suboptimal in this cohort of women with Type 2 diabetes. These poorer outcomes may be related to higher obesity, poor uptake of folic acid and the additional burden of hypertensive disorders in pregnancy.

# PS 091 Consequences of gestational diabetes

## Relationship of the incidence of gestational diabetes with the Mediterranean diet

**B. Karamanos**<sup>1</sup>, A. Thanopoulou<sup>1</sup>, E. Anastasiou<sup>2</sup>, M. Benrubi<sup>3</sup>, S. Assaad-Khalil<sup>4</sup>, M. Bachaoui<sup>5</sup>, C. Ben Slama<sup>6</sup>, N. El Bache<sup>7</sup>, H. El Ghomari<sup>8</sup>, N. Lalic<sup>9</sup>, A. Lapolla<sup>10</sup>, C. Saab<sup>11</sup>, C. Savona-Ventura<sup>12</sup>, J. Vassallo<sup>12</sup>, M. Marre<sup>13</sup>,  
<sup>1</sup>Diabetes Centre, 2nd Department of Internal Medicine, National University of Athens, Greece, <sup>2</sup>Alexandra Hospital, Athens, Greece, <sup>3</sup>Polikliniki, Athens, Greece, <sup>4</sup>University, Alexandria, Egypt, <sup>5</sup>University, Algiers, Algeria, <sup>6</sup>University, Tunis, Tunisia, <sup>7</sup>University, Damascus, Syrian Arab Republic, <sup>8</sup>University, Rabat, Morocco, <sup>9</sup>University, Belgrade, Serbia, <sup>10</sup>University, Rome, Italy, <sup>11</sup>University, Beirut, Lebanon, <sup>12</sup>University, Valetta, Malta, <sup>13</sup>University, Paris, France.

**Background and aims:** The relationship of the Mediterranean Diet with CVD is known but there are no reports for a possible relationship with Gestational Diabetes Mellitus (GDM). We aimed to explore the relationship of dietary habits and the Mediterranean Diet with the incidence of GDM in the Mediterranean region.

**Materials and methods:** Pregnant women (n=1083) from 10 Mediterranean countries underwent a 75 g OGTT at 24 - 32<sup>nd</sup> week of gestation which was interpreted by the American Diabetes Association (ADA) 2010 and the IADPSG 2012 criteria. Dietary habits were assessed by a 78-question dietary questionnaire, previously validated against the 3-Day Diet Diary and a Mediterranean Diet Score (SCORE) was computed, reflecting the degree of adherence to the Mediterranean Diet : a higher SCORE denoting better adherence.

**Results:** GDM incidence by ADA 2010 criteria was 9.5%, while by IADPSG 2012 29.0%. GDM +ve subjects by either criterion, compared to -ve were older, had higher BMI and more relatives suffering from diabetes. After adjustment for age, BMI, diabetes in the family, weight gain during pregnancy and energy intake, ADA 2010 GDM +ve subjects compared to -ve consumed less total (286 vs 308 g/d, p=0.029) and complex carbohydrates (155 vs 171 g/d, p=0.030), while fat contributed more to the energy intake (34.6 vs 33.0 %, p= 0.038). IADPSG 2012 GDM +ve subjects consumed also less total (298 vs 310 g/d, p<0.001) and complex carbohydrates (160 vs 174 g/d, p<0.001), while fat contributed more to the energy intake (35 vs 33%, p<0.001). Fat intake was positively correlated with fasting plasma glucose (FPG) and AUC glucose, while complex carbohydrate intake was negatively correlated with FPG and AUC glucose. These correlations remained significant if GDM +ve subjects were excluded, fat vs FPG  $r = 0.185$ ,  $p < 0.001$  and vs AUC glucose  $r = 0.074$ ,  $p = 0.027$ , complex carbohydrate vs FPG  $r = -0.188$ ,  $p < 0.001$  and vs AUC glucose  $r = -0.134$ ,  $p < 0.001$ . The adherence to Mediterranean Diet judged by the SCORE, was lower in GDM +ve subjects, diagnosed either by the ADA 2010 (SCORE 5.8 vs 6.3,  $p = 0.028$ ) or the IADPSG 2012 (SCORE 5.9 vs 6.4,  $p < 0.001$ ) criteria. A higher incidence of GDM was found in the lower tertile of SCORE distribution compared to the upper tertiles, both by the ADA 2010 (12.3 vs 8.0 %, OR=1.54,  $p = 0.030$ ) and IADPSG\_2012 (32.8 vs 24.3%, OR=1.35,  $p = 0.004$ ) criteria. Moreover, SCORE was negatively correlated with FPG and AUC glucose. This correlation remained significant if GDM +ve subjects were excluded, SCORE vs FPG  $r = -0.107$ ,  $p = 0.001$  and vs AUC glucose  $r = -0.117$ ,  $p < 0.001$ .

**Conclusion:** a) the known association of GDM incidence with high fat intake is confirmed and a further association with low total and complex carbohydrate intake is ascertained b) the correlation of SCORE, fat and carbohydrate intake with glucose levels exists also in GDM negative subjects c) a Mediterranean Diet pattern of eating may protect from the development of GDM

## The effect of GDM with the IADPSG criteria on offspring anthropometry in a multiethnic population, Norway

**K. Mørkrid**<sup>1,2</sup>, L. Sletner<sup>3,2</sup>, S. Vangen<sup>3</sup>, B. Nakstad<sup>4</sup>, A.K. Jenum<sup>1,2</sup>, K.I. Birkeland<sup>1,2</sup>;

<sup>1</sup>Endocrinology, Oslo University Hospital, <sup>2</sup>University of Oslo, <sup>3</sup>Obstetric and Gynaecology, Oslo University Hospital, <sup>4</sup>Child and Adolescents Medicine, Akershus University Hospital, Lørenskog, Norway.

**Background and aims:** Adiposity at birth or macrosomia (birth weight >4000 g) is associated with diabetes later in life. Increased adiposity at birth, not necessarily with increased birth weight, is reported in offspring to women with gestational diabetes (GDM). GDM is a risk factor for macrosomia, but most macrosomic babies are born to non-GDM women. The aim was to assess the effect of GDM with the International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria on the offspring's body fat and birth weight in a multiethnic population.

**Materials and methods:** Population-based cohort study of healthy pregnant women attending primary antenatal clinics in Eastern Oslo. In total 823 (74% of the invited) women, 59% with ethnic minority origin, were included at <20 weeks' gestation, and 759 performed the 75-g OGTT at 28 weeks' gestation. GDM was defined by slightly modified IADPSG criteria: FPG  $\geq 5.1$  mmol/l or 2-h PG  $\geq 8.5$  mmol/l (no 1-h PG). The offspring's birth weight, crown-heel-length, skin fold thickness (subscapular, suprailiac, triceps, thigh) were measured within 72 hours after birth. Totally 719 mothers with OGTT data and a singleton pregnancy had an offspring measured at birth. Ethnic origin: Western Europe (97% Scandinavia), South Asia, Middle East and Others. Simple descriptive, ANOVA, chi-square tests and linear regression analyses using SPSS 19.

**Result:** The GDM prevalence was 32% overall, higher for women from South Asia ( $p < 0.001$ ) and Middle East ( $p = 0.04$ ) compared with Western Europeans. No differences were found in the offspring's sex or gestational age between GDM and non-GDM women. Increased sum of skin folds was found in the offspring of GDM women compared with the non-GDM women (18.8 vs. 17.5 mm,  $p = 0.001$ ), which remained significant after adjustments for gestational age, parity and sex ( $\beta = 1.2$ ,  $p = 0.001$ ). GDM offspring were heavier at birth compared with the non-GDM offspring (3502 vs. 3405 g,  $p = 0.02$ ), also after adjustments as previously ( $\beta = 68.3$ ,  $p = 0.06$ ), and macrosomia was found in 20% vs. 12% respectively ( $p = 0.006$ ). Stratifying on ethnicity; the offspring's subscapular skin fold was increased for the GDM vs. the non GDM group for the South Asians and Middle Easterners ( $p < 0.05$ ), not for Western Europeans. Only for the South Asians, the offspring's birth weight was higher in the GDM vs. the non-GDM group ( $p < 0.001$ ), also after adjustments as previously ( $\beta = 165.3$ ,  $p = 0.008$ ).

**Conclusion:** Women identified with GDM with the IADPSG criteria delivered larger babies with greater adiposity compared with non-GDM women. Offspring to South Asian and Middle Eastern GDM women, compared with non-GDM, had increased subscapular skin folds, a surrogate measure of visceral fat. The effect of GDM on birth weight was more prominent among South Asians.

# Neonatal birth weight in women with gestational diabetes defined by International Association of Diabetes in Pregnancy Study Group (IADPSG) criteria

V. Resi<sup>1</sup>, E. Lacaria<sup>1</sup>, A. Ghio<sup>1</sup>, G. Nosiglia<sup>2</sup>, L. Battini<sup>2</sup>, A. Carmignani<sup>2</sup>, P. Bottone<sup>2</sup>, L. Volpe<sup>1</sup>, S. Del Prato<sup>1</sup>, A. Bertolotto<sup>1</sup>;

<sup>1</sup>Endocrinology and Metabolism, <sup>2</sup>Ob/Gyn Unit II, Azienda Ospedaliero, University of Pisa, Italy.

**Background and aims:** The International Association of Diabetes and Pregnancy Study Groups (IADPSG) has recommended new criteria for diagnosis of gestational diabetes (GDM). The aim of our study was to evaluate the impact of new diagnostic criteria on the outcome of pregnancy in women with GDM.

**Materials and methods:** Out 962 unselected pregnant women screened by IADPSG criteria, 203 were diagnosed with GDM (GDM-IADPSG) (age  $34 \pm 5$  years; family history of diabetes: 19%; primiparous: 54%; previous GDM: 3.4%; pre-pregnancy BMI  $24.4 \pm 4.6$  kg/m<sup>2</sup>; BMI  $\geq 30$  Kg/m<sup>2</sup> 9.8%). HbA1c was assessed at 36 weeks of pregnancy. Maternal and fetal data were collected at delivery and perinatal time to be compared with those of 251 women with normal glucose tolerance (NGT) (age  $33 \pm 5$  years; family history of diabetes: 16%; primiparous: 51%; pre-pregnancy BMI  $22.7 \pm 3.8$  kg/m<sup>2</sup>, BMI  $\geq 30$  Kg/m<sup>2</sup> 8.4%). A random sample of women (age  $35 \pm 5$  years; family history of diabetes: 33%, primiparous: 54%; pre-pregnancy BMI  $24.1 \pm 4.7$  kg/m<sup>2</sup>, BMI  $\geq 30$  Kg/m<sup>2</sup> 8.9%) with GDM diagnosed according to ADA criteria before October 2010 (GDM-ADA) was also identified.

**Results:** At pregnancy term all GDM women had normal and comparable HbA1c levels (GDM-IADPSG:  $5.4 \pm 0.3\%$ ; GDM-ADA  $5.2 \pm 0.5\%$ ,  $p = \text{NS}$ ) with no significant difference in the caesarean delivery rate (GDM-IADPSG 42%, GDM-ADA 42.2%) compared to NGT (33%). Similarly there was no significant difference with respect to macrosomia (GDM-IADPSG (8.3%; GDM-ADA 9.2%; NGT 7.3%). Whereas there was no difference in LGA between GDM-IADPSG (0%) and NGT (1%), incidence was greater in GDM-ADA (14.2%). No difference was apparent in the Ponderal Index among the 3 GDM groups (NGT  $2.60 \pm 0.28$ ; GDM-IADPSG  $2.57 \pm 0.24$ ; GDM-ADA  $2.59 \pm 0.25$ ).

**Conclusion:** Our analysis suggests that the use of the new IADPSG criteria does not result in any further improvement in metabolic, maternal and neonatal outcomes with the exception of a decrease of LGA as compared to the ADA criteria.

## 1073

# Second trimester postload glucose level as an important predictor of low birth weight infant: Tanaka women's clinic study

Y. Yachi<sup>1,2</sup>, Y. Tanaka<sup>2</sup>, I. Nishibata<sup>3</sup>, M. Yasuhara<sup>4</sup>, K. Kobayashi<sup>4</sup>, T. Matsuoka<sup>2</sup>, A. Sugawara<sup>1</sup>, S. Kodama<sup>1</sup>, K. Saito<sup>1</sup>, H. Sone<sup>1</sup>;

<sup>1</sup>Department of Endocrinology and Metabolism, University of Tsukuba Institute of Clinical Medicine, Mito, <sup>2</sup>Department of Obstetrics and Gynecology, Tanaka Women's Clinic, Tokyo, <sup>3</sup>Nursing department, Kawasaki City College of Nursing, <sup>4</sup>Department of Obstetrics and Gynecology, Japan Maternity Fitness Association, Tokyo, Japan.

**Background and aims:** Birth weight is known to affect not only perinatal health or subsequent growth/development but also morbidity in later life. Especially low birth weight (LBW) is now recognized as an established risk for future metabolic abnormalities, including obesity and diabetes. Although it is well known that hyperglycemia is an important risk factor for macrosomia, whether maternal glucose levels are associated with incident neonatal LBW is unknown. We therefore examined the associations between maternal glycemia with normal glucose tolerance and the risk of LBW births in Japanese mothers.

**Materials and methods:** Prospectively observed were 592 consecutive singleton pregnant women without recognized diabetes before the pregnancy who initially visited the obstetric clinic before 13 weeks gestation. At the first prenatal visit and at a mean gestational age of  $27.9 \pm 1.0$  weeks, a blood sample was collected in early morning after an 8-h overnight fast. Furthermore, a 50 g glucose challenge test (GCT) was done between 26–29 weeks gestation. LBW was determined as an infant with a birth weight of less than 2500g.

**Results:** Of the 35 women who were excluded from the study, 28 had gestational diabetes mellitus and 7 had pregnancy-induced hypertension, which might affect fetal growth. Out of 557 deliveries, 22 (4%) were LBW infants at full term. By multivariate logistic regression analysis that included maternal

age, parity, BMI at first prenatal visit, height, gestational age, and sex of the newborn, we observed a statistically significant inverse association between the 1-h postload glucose level of the GCT (1hGCT) and LBW incidence (odds ratio 0.77 per 10 mg/dl increments, 95%CI, 0.63–0.95). Compared with women in the highest 3 quartiles of 1hGCT ( $>108$  mg/dl), women in the lowest quartile ( $\leq 108$  mg/dl) had a 3.92-fold (1.60–9.57) higher risk for LBW births.

**Conclusion:** A low 1hGCT level (within normal glucose range) was highly associated with an increased risk of LBW births in Japanese mothers with normal glucose tolerance.

Table 1: Risk of LBW newborns by fasting and 1-h postload glucose in 557 singleton pregnancies.

Variables	Model 1 (95% CI)	P	Model 2 (95% CI)	P
1 <sup>st</sup> Trimester fasting plasma glucose	0.97 (0.91–1.03)	0.312	0.97 (0.92–1.03)	0.349
2 <sup>nd</sup> Trimester fasting plasma glucose	0.93 (0.85–1.01)	0.412	0.94 (0.86–1.03)	0.201
2 <sup>nd</sup> Trimester 1h postload glucose	0.97 (0.95–0.99)	0.013	0.97 (0.96–0.99)	0.013
2 <sup>nd</sup> Trimester 1h postload glucose categories				
10mg/dl increments	0.74 (0.61–0.90)	0.012	0.77 (0.63–0.95)	0.013
Q2–Q4: $>108$ mg/dl	1 (referent)		1 (referent)	
Q1: $\leq 108$ mg/dl	4.02 (1.79–9.89)	0.010	3.92 (1.60–9.57)	0.013

Data are Odds Ratio (95% CI). Model 1 is adjusted for parity, gestational age, and sex of the newborn. Model 2 is adjusted for parity, gestational age, sex of the newborn, maternal age, BMI at first prenatal visit, and maternal height.

# The impact of ethnicity on glucose homeostasis after gestational diabetes mellitus

C. Ignell<sup>1</sup>, N. Shaat<sup>2</sup>, M. Ekelund<sup>3</sup>, K. Berntorp<sup>2</sup>;

<sup>1</sup>Dept of Obst and Gyn, Helsingborg, <sup>2</sup>Dept of Endocrinology, Skåne University Hospital, Malmö, <sup>3</sup>Dept of Int Med, Helsingborg, all authors affiliated to Dept of Clinical Sciences, Malmö, Lund University, Sweden.

**Background and aims:** Ethnicity influences the prevalence of gestational diabetes (GDM) and its progression to manifest diabetes postpartum, being higher in non-European populations. This may partly be explained by differences in insulin secretion and action. Aims of the present study were to evaluate glucose homeostasis after GDM, the impact of ethnicity and other determinants of glucose tolerance postpartum.

**Material and methods:** Women in southern Sweden undergoing a 75 g oral glucose tolerance test (OGTT) during pregnancy in 2003–2005 were invited to follow-up postpartum. Diagnostic criteria were those defined by the WHO in 1999. At 1–2 years after delivery 470 women with GDM and 166 women with normal glucose tolerance (NGT) during pregnancy performed an OGTT with measurements of plasma glucose and insulin concentrations at fasting, 30 min and 120 min. Homeostasis model assessment (HOMA-IR) was used to estimate insulin resistance. Beta cell function was quantified as the ratio of the incremental insulin to glucose during the first 30 min of the OGTT (I/G30). The disposition index was used to adjust insulin secretion for the degree of insulin resistance ( $[I/G30]/\text{HOMA-IR}$ ). Women were grouped according to ethnicity based on stated country of origin in at least three of their grandparents. Indices were log transformed and differences in means were tested by ANCOVA, adjusting for age, parity and interval to follow-up (results given as geometric mean [95% confidence interval (CI)]). Frequency differences were tested by the Chi-square test. Multivariate logistic regression analysis was used to assess the association of known predictor variables (age, BMI, parity, first degree relative(s) with diabetes, non-European origin) with diabetes postpartum, adjusting for time to follow-up.

**Results:** Comparing women with previous GDM ( $n=470$ ) to controls (NGT during pregnancy and follow-up,  $n=150$ ), the former had higher HOMA-IR

(1.5 [1.4–1.7] vs. 1.3 [1.2–1.5],  $p=0.020$ ) and lower disposition index (8.4 [7.7–9.2] vs. 12.8 [10.8–15.2],  $p<0.001$ ). These differences were more pronounced in women with GDM who had diabetes postpartum (HOMA-IR 3.1 [2.2–4.4], disposition index 2.6 [1.9–3.7]) compared to controls ( $p<0.001$ ), while those who stayed normoglycaemic had similar HOMA-IR as controls but lower disposition index (9.6 [8.7–10.6],  $p<0.001$ ). Among women with GDM, estimates of beta cell function did not differ between non-European ( $n=94$ ) and European women ( $n=362$ ), whereas non-European women were more insulin resistant (HOMA-IR 2.0 [1.7–2.3] vs. 1.5 [1.3–1.6],  $p=0.002$ , after adjustment for BMI  $p=0.015$ ). Similarly, Arabic women ( $n=41$ ) had higher HOMA-IR (2.1 [1.6–2.7]) than European women ( $p=0.006$ ), but insignificant after adjustment for BMI. Non-European origin was associated with higher frequency of diabetes at follow-up (16%) than was European origin (4%,  $p<0.001$ ). Of the predictor variables tested for an association with diabetes after GDM, BMI and non-European origin showed the highest associations; odds ratio (95% CI), 1.1 (1.1–1.2),  $p<0.001$ , and 5.3 (1.9–14.9),  $p=0.002$ , respectively.

**Conclusions:** Women with a history of GDM display abnormalities in glucose homeostasis, also in the presence of NGT postpartum, including beta cell dysfunction and insulin resistance. These derangements may be influenced by ethnicity and BMI.

### The features of blood glucose in gestational diabetes mellitus women during pregnancy and after delivery

Y. Li<sup>1</sup>, Y. Liu<sup>1</sup>, C. Han<sup>2</sup>, J. Li<sup>1</sup>, Y. Zhao<sup>3</sup>, L. Shi<sup>1</sup>

<sup>1</sup>Endocrinology, The Second Hospital of Jilin University, <sup>2</sup>Obstetrics and Gynecology, Obstetrics and Gynecology Hospital of Changchun, <sup>3</sup>Isotope, The Second Hospital of Jilin University, Changchun, China.

**Background and aims:** Gestational diabetes mellitus (GDM) affects mother and infant's health. And after delivery, the incidence of type 2 diabetes and metabolic syndrome of GDM women will significantly increase. In this study, we obtained blood glucose profiles of gestational diabetes mellitus (GDM) in the late second or early third trimester of pregnancy and after delivery within 6 months by the continuous glucose monitor system (CGMS), to evaluate the relationship between glycemic excursions and pregnancy outcomes and to find the characteristic of blood glucose in GDM women during pregnancy and after delivery.

**Materials and methods:** The study has been reviewed by the Local Ethics Committee. 33 pregnant women who were diagnosed with GDM in the late second or early third trimester of pregnancy were treated according to blood glucose level. The continuous glucose monitor system (CGMS) was worn for 72h after the blood glucose levels were stabilized to fasting glucose  $\leq 5.6$  mmol/L and to 2-h postprandial blood glucose  $\leq 6.7$  mmol/L during pregnancy and after delivery within 6 months. At the same time, OGTT, insulin and C-peptide level were tested.

**Results:** During pregnancy, blood glucose results monitored by CGMS had good correlation with finger-stick values ( $r = 0.876$ ,  $P < 0.01$ ), regardless of implantation in the arm or the waist, and the waist had the better correlation. The correlations between two groups were analyzed by the Pearson coefficient analysis. HbA1C levels and the mean amplitude of glycemic excursion (MAGE) significantly contributed to poor pregnancy outcomes. Adverse pregnancy outcomes-related factors were performed by a Logistic regression model.  $P < 0.05$  was considered statistically significant. After delivery, the occurrence of type 2 diabetes in GDM was related to blood glucose levels during pregnancy, regardless of the pre-pregnancy BMI, pregnancy weight gain and C-peptide levels. The blood glucose level of GDM women after delivery within 6 months was significantly lower than they were during pregnancy. And MAGE and MODD were significantly reduced in GDM women when they were after delivery.

**Conclusion:** CGMS can accurately reflect the blood glucose profile of GDM women, and waist was the best implantation site to wear CGMS. In GDM patients. The insulin treatment raised the glucose variability compared with diet only, although the patients had similar HbA1C levels, which contributed to poor pregnancy outcomes. We should strengthen the postpartum follow-up, especially in GDM women with poor glycemic control during pregnancy.

## 1076

### Applicability of a combination of HbA<sub>1c</sub> and fasting plasma glucose in post-partum screening of women with gestational diabetes mellitus

D. Benaiges<sup>1</sup>, J. Chillaron<sup>1</sup>, E. Sagarra<sup>1</sup>, A. Paya<sup>2</sup>, E. Hernandez<sup>1</sup>, E. Corominas<sup>1</sup>, J. Puig<sup>1</sup>, M. Carrera<sup>1</sup>, M. Renard<sup>1</sup>, A. Mas<sup>1</sup>, C. Bosch<sup>1</sup>, A. Goday<sup>1</sup>, J. Flores<sup>1</sup>

<sup>1</sup>Endocrinology and Nutrition, <sup>2</sup>Gynecology and Obstetrics, Hospital Universitari del Mar, Barcelona, Spain.

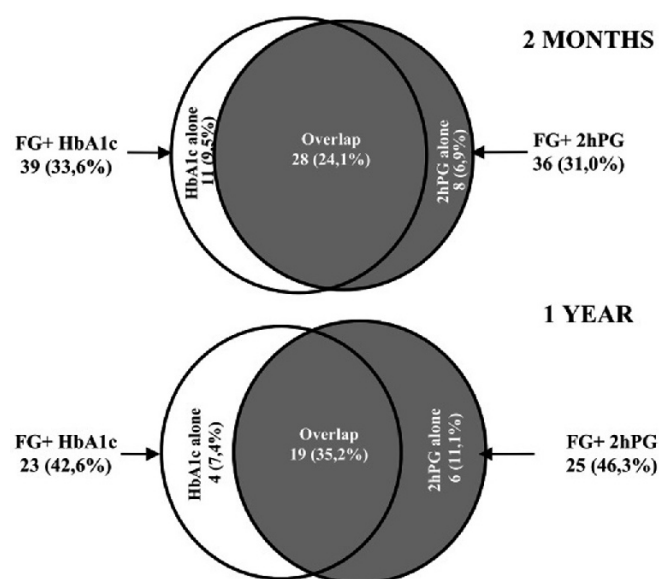

**Background and aims:** Patients with a history of gestational diabetes mellitus (GDM) have a greatly increased risk of subsequent DM. Therefore, practice guidelines recommend post-partum screening of carbohydrate metabolism and OGTT is the preferred method. A combination of HbA<sub>1c</sub>-fasting plasma glucose (FPG) has been suggested as a more practical and effective screening method. Nevertheless, little is known about the applicability of this combination for post-partum screening. The purpose of this study is to determine (a) concordance between a combination of HbA<sub>1c</sub> and FPG (HbA<sub>1c</sub>+FPG) and a combination of FPG and 2 hour plasma glucose (2hPG) (FPG+2hPG), and (b) whether substituting FPG+2hPG with HbA<sub>1c</sub>+FPG can be more cost-effective in the detection of preDM and DM in the post-partum of women with GDM.

**Materials and methods:** Prospective analysis of women diagnosed with GDM between 2006 and 2010. Women were scheduled for an OGTT and HbA<sub>1c</sub> at 2 months and 1 year post-partum. PreDM and DM were defined following the American Diabetes Association criteria. HbA<sub>1c</sub> was measured using NGSP/DCCT% units. Concordance between FPG+2hPG and HbA<sub>1c</sub>+FPG was analyzed by means of sensitivity, specificity and positive and negative predictive values. The cost of the diagnostic tests was calculated taking into account use of reagents, laboratory labour and profit and hours lost at work.

**Results:** 375 women were scheduled and 130 (34.7%) underwent post-partum screening; 116 at 2 months, 54 at one year, and 40 at both times. Women who underwent screening had a mean age of  $34.2 \pm 4.8$  years, a mean BMI of  $26.9 \pm 4.8$  Kg/m<sup>2</sup>, and 53.1% were Caucasian. No cases of DM were diagnosed at 2 months and 4 cases were diagnosed at one year. Prevalence of preDM was 40.5% at 2 months and 46.3% at one year. For overall glucose metabolism anomalies, A1c+FPG compared with FPG+2hPG had a sensitivity of 77.7%, a specificity of 86.3%, a positive predictive value of 71.8% and a negative predictive value of 89.6% at two months post-partum and 76%, 86.2%, 82.6% and 80.6% at one year, respectively. The figure shows the number of cases diagnosed with each technique (FPG+2hPG and HbA<sub>1c</sub>+FPG) at 2 months and one year post-partum. The estimated cost of using HbA<sub>1c</sub>+FPG as the screening test was 8.913 euros and the cost of OGTT was 13.386 euros (cost of hours lost at work was only included at one year screening). Use of HbA<sub>1c</sub>+FPG associates a 33% cost reduction.

**Conclusion:** HbA<sub>1c</sub>+FPG values show a good concordance with OGTT results for pre-DM and DM diagnosis, with a similar number of detected cases. Combined HbA<sub>1c</sub>+FPG has a significant cost reduction when compared with OGTT and could be a more efficient diagnostic test for post-partum screening of women with GDM. Nevertheless, the use of exclusively one of these two options underdiagnoses approximately 10% of the cases.

## 1077

### ATLANTIC DIP: the prevalence of pre-diabetes/diabetes up to 5 years post partum in women with previous gestational diabetes along the Atlantic coast

E. Noctor<sup>1</sup>, C. Crowe<sup>1</sup>, L.A. Carmody<sup>1</sup>, B. Wickham<sup>1</sup>, G. Avalos<sup>1</sup>, G. Gaffney<sup>2</sup>, P. O'Shea<sup>1</sup>, F. Dunne<sup>1</sup>;

<sup>1</sup>Department of Medicine, <sup>2</sup>Department of Obstetrics/Gynaecology, University Hospital, Galway, Ireland.

**Background and aims:** Gestational diabetes (GDM) is increasing in Ireland. Figures from our population show a 12.4% prevalence during a period of universal screening using IADPSG (International Association for Diabetes in Pregnancy Study Group) criteria. Women with GDM have a higher lifetime risk of diabetes, but most studies have involved heterogeneous populations—the applicability of this to our population is unclear.

**Materials and methods:** We invited women with a history of GDM (IADPSG criteria) in the preceding 5 years to repeat screening using a 75g OGTT to assess progression to pre-diabetes/diabetes (American Diabetes Association criteria for impaired fasting glucose/impaired glucose tolerance/ type 2 diabetes). 194 women with a GDM history were compared with 299 women with normal glucose tolerance (NGT) in pregnancy during the same period. Pearson's chi-squared test was used to estimate differences in population proportion. Logistic regression analysis was used to identify factors associated with progression to pre-diabetes/diabetes (SPSS v18).

**Results:** 14% (22/157) of GDM women rescreened had pre-diabetes/diabetes, in addition to 37 women known to have abnormal glucose tolerance within 6 months of pregnancy, giving a prevalence of 30.4% (59/194) compared to 3.3% (10/299) of women with NGT during pregnancy ( $p=0.000$ ). Index pregnancy factors associated with pre-diabetes/diabetes were; fasting glucose of 5.6 mmol/L or greater during pregnancy (OR 3.2, 95% CI 1.3,7.5,  $p=0.009$ ), week of gestation at GDM diagnosis (OR 0.9 per additional week, 95% CI 0.84, 0.99,  $p=0.033$ ) and insulin use (OR 2.9, 95% CI 1.3, 6.5,  $p=0.011$ ). Breastfeeding for greater than one month was associated with a reduction in risk (OR 0.47, 95% CI 0.23,0.97,  $p=0.40$ ). Factors at rescreening associated with pre-diabetes/diabetes were metabolic syndrome (ATPIII criteria-OR 5.1, 95% CI 2.5,10.6,  $p=0.000$ ), and higher HbA1c (OR 1.3 per 1mmol/mol increase, 95% CI 1.1,1.4,  $p=0.000$ ). Age at delivery, BMI, and time since delivery were not associated with pre-diabetes/diabetes.

**Conclusion:** The high prevalence of diabetes/pre-diabetes at this short interval (mean 2.47 years, SD 1.0) suggests a robust national rescreening program level is warranted. Further economic analysis may help to clarify what form such a program should take.

## 1078

### Hypertension and end stage renal disease in women with a past history of gestational hypertension associated with diet

F. Jebunnesa<sup>1</sup>, K. Jahan<sup>2</sup>, S. Sultana<sup>3</sup>, H. Chowdhury<sup>4</sup>, L. Ali<sup>5</sup>;

<sup>1</sup>Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences, <sup>2</sup>Gynecology & Obstetrics, Shahid Showrawardy Hospital,

<sup>3</sup>Health Informatics, Bangladesh Institute of Health Sciences, <sup>4</sup>Biostatistics, Bangladesh Institute of Health Sciences, <sup>5</sup>Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh.

**Background and aims:** We have previously shown showed that Pregnancy Induced Hypertension (PIH) is associated with hypertension in a later period after delivery. The present study was undertaken to test the hypothesis that dietary factor(s) are implicated in the association between GH and later life hypertension

**Materials and methods:** Under a cross sectional design and a total of 140 women (age, 32.4±8.1 yrs, and BMI 25.1±4.1, kg/m<sup>2</sup>, M±SD) with a previous history of PIH in any pregnancy were included. Clinical, anthropometric and biochemical parameters were measured by standard techniques. Systolic blood pressure of 130 mmHg, diastolic blood pressures of 90 mmHg or mean blood pressure of >150mmHg were taken as cut-off values for hypertension (Htn). Dietary intakes were assessed by Food Frequency Questionnaire (24 hr recall methods).

**Results:** Out of 140 women 49 (35%) developed Htn and 46 (32.9%) developed ESRD over a duration of 5 to 12 yrs. Forty five (32%) of the subjects had both the complications. The hypertensive subjects (Htn) had higher uric acid (mg/dl, 7.38±1.1 vs 4.6±1.6;  $p<0.001$ ) and total protein (mg/dl, 125.3±43.6 vs 57±20.8;  $p<0.001$ ) compared to the Non-Htn subjects. Total energy intake was higher in Htn [kcal, 2175.7±399.6] as compared to non-Htn [1239±483] subjects. The higher energy was contributed mainly by carbohydrate sources from rice (g/day, 582.1±6 vs 239±71.9). On logistic regression analysis, htn showed a strong positive association with past history of PIH and total energy intake when the effects of age and BMI, past history of Htn, serum uric acid and Triglyceride were adjusted.

**Conclusion:** Women with past history of PIH have more chance of developing hypertension and it may have an association with increased energy intake from carbohydrate sources.

## PS 092 Biomarkers in gestational diabetes mellitus

1079

### Comparative evaluation of the periodontal status and plaque microbial flora in gestational diabetic and non-diabetic pregnant women: a clinico-microbiological study

S.V. Kothiwale<sup>1</sup>, V.A. Kothiwale<sup>2</sup>, A. Kumar<sup>1</sup>, P.V. Bhargava<sup>1</sup>;

<sup>1</sup>Periodontics, KLE V.K Institute of Dental Sciences, <sup>2</sup>General Medicine, Jawaharlal Nehru Medical College, Belgaum, India.

**Backgrounds and aims:** Periodontal disease is one of the most common chronic disorders of infectious origin of the supporting structures of the teeth. It is associated with an increased risk of systemic diseases such as cardiovascular diseases, diabetes mellitus and adverse pregnancy outcomes. Maternal glucose disorders during pregnancy include gestational diabetes mellitus. Diabetic retinopathy, macrosomia are common in babies born to women with pre-existing diabetes. Despite the advances in prenatal care and public awareness, adverse pregnancy outcomes still present a major public health problem worldwide. Infection is an important contributor to complications of pregnancy. Pregnant women have been found to have an increased level of periodontal infection compared with non-pregnant women of the same age. The severity of periodontal infection during pregnancy has been found to be associated with the presence of *P. gingivalis* and *P. intermedia*, leading to an increase in the adverse pregnancy outcomes. Hence, an accurate quantification of the number of individual bacterial species in dental plaque samples is needed for understanding the contribution of bacterial etiology in gestational diabetes mellitus and non diabetic pregnant women.

**Aim:** Assessment and comparison of the periodontal status and quantitative analysis of plaque microbial flora by polymerase chain reaction (PCR) in gestational diabetes mellitus patient and non diabetic pregnant women.

**Material and methods:** Initially 800 primi pregnant women were screened. Among them 60 were selected for case control study who met with inclusion and exclusion criteria. The group A included 30 gestational diabetic pregnant women and group B included 30 healthy pregnant women. Each patient was subjected for periodontal examination using gingival index, periodontal index and probing pocket depth and microbial analysis with the plaque sample. Microbiological analysis was done by PCR. The statistical analysis was carried out by student -t Test, Chi- square test and Fisher Exact test.

**Results:** The results showed statistical significant difference in gingival index (0.007), periodontal disease index (plaque index ,0.004 and periodontal pocket depth, 0.011) between gestational diabetic group and healthy pregnant group. The blood glucose parameters between the two groups was statistical significant at P value <0.001. The presence of high value of *P. intermedia* and *P. gingivalis* was positively associated in group A at P value = 0.175 and 0.007 respectively, by PCR.

**Conclusion:** The study showed an association between periodontal disease and gestational diabetes mellitus. Periodontal disease may contribute to the development of diabetes in women with the history of gestational diabetes mellitus. If the periodontal disease is confirmed as risk factor for GDM in future studies, it might provide a window of opportunity for early interventional studies. Thus it is imperative to prevent and treat periodontal disease before or during pregnancy so as to reduce maternal and infant morbidity associated with GDM.

1080

### Factors that influence fasting ketonemia and ketonuria in gestational diabetes mellitus (GDM)

E. Anastasiou<sup>1</sup>, L. Spanou<sup>1</sup>, K. Dalakleidi<sup>2</sup>, K. Zarkogianni<sup>2</sup>, A. Papadimitriou<sup>1</sup>, K. Nikita<sup>2</sup>, M. Alevizaki<sup>1</sup>, V. Vasileiou<sup>1</sup>;

<sup>1</sup>Alexandra Hospital, <sup>2</sup>Faculty of Electrical and Computer Engineering, National Technical University of Athens, Athens, Greece.

**Background:** The use of capillary blood  $\beta$ -hydroxybutyrate (3HB), a quantitative measurement, is a more precise method than urine ketones measurement (semi-quantitative detection of acetoacetate acid) for the diagnosis of diabetic ketoacidosis. Fasting ketonuria is common during normal pregnancy while there is evidence of increased frequency among pregnant women with GDM on diet. Ketone bodies cross the placenta while 3HB has been related to impaired offspring psychomotor development. Reports with

concomitant measurement of blood and urine ketones in GDM women are lacking.

**Aim:** To compare the incidence of fasting ketonemia and ketonuria in GDM women and assess their possible relation with metabolic parameters and therapeutic interventions.

**Methods:** Blood glucose, capillary blood ketones (Glucomen LX  $\beta$ -ketone, Menarini ) and urine ketones (Ketostix, Bayer) were simultaneously measured in 280 GDM pregnant women (age: 33.0 $\pm$ 0.3 years, pre-pregnancy BMI 27.05 $\pm$ 5.86kg/m<sup>2</sup>) in serial visits (total measurements: 378). 3HB levels were defined as negative (0-0.6mmol/l), intermediate (0.6-1.5mmol/l) or positive (1.5-3mmol/l). Age, prepregnancy BMI, gestational age, body weight change per gestational week, insulin treatment and bedtime carbohydrate intake were recorded.

**Results:** 3HB levels were: negative 352/378(93.1%), intermediate 20/378(5.3%) and positive 6/378(1.6%). Incidence of ketonuria was: negative 245/378 (64.8%), +/+ 84/378 (22.2%) and +++/+++ 49/378 (13%). The incidence of ketonuria was significantly higher than that of ketonemia ( $\chi^2=21.33$ ,  $p<0.001$ ). Mean 3HB levels differed significantly depending on ketonuria severity (ketonuria 0- 3HB= 0.1 $\pm$ 0.01mmol/l, (+/+) - 3HB= 0.21 $\pm$ 0.03mmol/l, (+++/+++ ) - 3HB= 0.55 $\pm$ 0.08mmol/l  $p=0.001$ ). Bed-time carbohydrate intake was associated with significantly lower 3HB levels compared to omission of the snack (3HB= 0.16 $\pm$ 0.02 vs 0.23 $\pm$ 0.03mmol/l,  $p=0.035$ ). Insulin treatment was associated with significant 3HB reduction (0.15 $\pm$ 0.02 vs 0.22 $\pm$ 0.03mmol/l,  $p=0.032$ ). Body weight reduction/week between two serial visits was associated with increased 3HB levels compared to weight gain/week (3HB 0.23 $\pm$ 0.05 vs 0.10 $\pm$ 0.02mmol/l,  $p=0.005$ ). Age correlated positively with 3HB ( $r=0.16$ ,  $p=0.002$ ). Multiple linear regression analysis showed that weight loss remained the only independent predictor of 3HB levels when age, BMI, insulin treatment and bedtime carbohydrate intake were taken into account ( $p=0.006$ ). The influence of meal intake and insulin treatment was no longer observed. Finally no correlation between 3HB and age, gestational age, parity, blood glucose levels or HbA1c was observed.

**Conclusion:** Abnormally high blood ketone levels were observed in a minor percentage (1.6%) of pregnant women with GDM, in contrast to the high presence of ketonuria (35.2%). The clinical significance of the small increase of 3HB levels, although within normal limits, in pregnant women whose body weight was reduced, requires further investigation.

1081

### The type 2 diabetes genetic risk variant TCF7L2 rs7903146 is differentially associated with gestational diabetes: differences between central and Mediterranean Europeans

L. Potasso<sup>1</sup>, N. Perakakis<sup>1</sup>, A. Lamprinou<sup>1</sup>, E. Polyzou<sup>2</sup>, D. Kassanos<sup>2</sup>, A. Peter<sup>3</sup>, R. Rasenack<sup>4</sup>, G. Paeth<sup>1</sup>, J. Seufert<sup>1</sup>, K. Laubner<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine II, University Hospital of Freiburg, Germany, <sup>2</sup>3rd Department of Obstetrics and Gynecology, University Hospital Attikon, Athens, Greece, <sup>3</sup>Department of Internal Medicine IV, University Hospital of Tuebingen, Germany, <sup>4</sup>Department of Gynecology and Obstetrics, University Hospital of Freiburg, Germany.

**Background and aims:** Single nucleotide polymorphisms (SNPs) within the transcription factor 7-like 2 (TCF7L2) gene are well known risk variants for type 2 diabetes. The best studied SNP is rs7903146, which is additionally associated with insulin secretion and BMI. Here we assess and compare the effect of this TCF7L2 risk variant on the development of gestational diabetes mellitus (GDM) in two populations of women of German and Greek origin.

**Materials and methods:** We genotyped the C/T polymorphism of the TCF7L2 gene variant rs7903146 in 96 unrelated women with a history of GDM (Greek n=50, German n=46), and in 93 women with type 2 diabetes mellitus (DM2) (Greek n= 43, German n=50) and in 155 non-diabetic pregnant women (Greek n=80, German n=75) as controls. The prevalences of non-risk CC, and risk TT alleles in the three groups were compared for Greek and German patients, both in combined and in separate country specific analysis sets.

**Results:** In the combined analysis sets of GDM vs non-diabetic pregnant women, the TT genotype of the TCF7L2 gene variant rs7903146 was significantly associated with an increased risk of GDM as compared to the non-risk CC allele [ $p=0.011$ ; Odds Ratio (OR)=3.17; 95%CI=1.318-7.665]. This risk association was particularly strong and driven by the Greek cohort [ $p=0.043$ ; OR=3.39; 95%CI=1.097-10.49], while a much weaker association was observed in the German cohort [ $p=0.13$ ; OR=3.26; 95%CI=0.72-14.7]. The CT genotype was similarly represented in both GDM and non-diabetic pregnant women, with no significant difference between German and Greek cohorts [ $p=0.83$ ]. No significant differences were detected between the GDM and

DM2 groups when comparing the presence of TT and CC genotype [OR = 1; p=1; 95%CI= 0.45–2.5]. As control, we found an association between TT genotype and DM2 when comparing both control groups [p=0.029; OR= 2.96; 95% CI=1.19–7.34].

**Conclusion:** Our data suggest significant variability of GDM risk conferred by the TCF7L2 rs7903146 TT allele even within two European populations of primary Caucasian origin. This novel observation could imply a much higher influence of the genetic background within the same ethnicity on the TCF7L2 associated risk for GDM than previously thought.

## 1082

### First trimester maternal weight predicts cord blood c-peptide levels while first trimester maternal fasting visfatin levels predict birth weight in normal pregnancy

G. Valsamakis<sup>1</sup>, D. Papatheodorou<sup>2</sup>, A. Margeli<sup>3</sup>, V. Bakoulas<sup>2</sup>, E. Kapantais<sup>4</sup>, I. Papassotiropoulos<sup>3</sup>, S. Kumar<sup>5</sup>, G. Mastorakos<sup>2</sup>;

<sup>1</sup>Endocrine Unit, Aretaieion University Hospital, Athens, Greece, <sup>2</sup>Endocrine Unit, 2nd Dept Obs&Gynae, Aretaieion University Hospital, Athens, Greece, <sup>3</sup>Biochemistry, Aghia Sofia Childrens Hospital, Athens, Greece, <sup>4</sup>Diabetes Obesity Metabolism, Metropolitan Hospital, Athens, Greece, <sup>5</sup>Diabetes Obesity Metabolism, Warwickshire Institute for the Study of Diabetes, Endocrinology and Metabolism, Coventry, UK.

**Background and aims:** Fetal growth and metabolism depend on intra-uterine metabolic environment and pregnancy-associated insulin resistance. The role of first trimester maternal weight and adipose tissue markers into birth weight and cord blood c-peptide and adipocytokines in normal pregnancy was investigated.

**Materials and methods:** Seventy pregnant nonobese, nondiabetic Caucasian women were recruited randomly. Anthropometric measurements, 75 gr OGTT and fasting adipocytokines (visfatin, leptin, adiponectin, IL6) were performed at each of the 3 trimesters. At birth, birth weight and cord blood c-peptide, glucose, insulin, visfatin, leptin, adiponectin and IL6 in each of neonates were measured.

**Results:** First trimester maternal weight correlated positively and negatively with cord blood c-peptide (p=0.035, r=0.74) and cord blood visfatin (p=0.049, r=-0.67), respectively. First trimester insulin resistance (HOMAR) was negatively and positively correlated with cord blood visfatin (p=0.037, r=-0.90) and leptin (p=0.031, r=0.90), respectively. First trimester maternal weight was positive predictor of cord blood c-peptide (p=0.007). First trimester maternal visfatin levels were negative predictors of birth weight (p=0.017).

**Conclusion:** First trimester maternal weight and adipose tissue metabolism markers seem to be strongly associated with final birth weight and fetal insulin secretion suggesting the role of early-pregnancy maternal adipose tissue upon pregnancy metabolic environment as well as genetic predisposition from the mother.

### Levels of the inflammatory marker YKL-40 in young adults exposed to intrauterine hyperglycaemia

L. Kelstrup<sup>1,2</sup>, T.F. Deigaard<sup>3</sup>, T.D. Clausen<sup>1</sup>, E.R. Mathiesen<sup>4,5</sup>, T. Hansen<sup>6,7</sup>, H. Vestergaard<sup>3,8</sup>, P. Damm<sup>1,8</sup>;

<sup>1</sup>Center for Pregnant Women with Diabetes, Department of Obstetrics, Rigshospitalet, Copenhagen, <sup>2</sup>Danish PhD School of Molecular Metabolism, Odense University Hospital, <sup>3</sup>Center of Endocrinology and Metabolism, Department of Medicine O, Copenhagen University Hospital Herlev, <sup>4</sup>Center for Pregnant Women with Diabetes, Department of Endocrinology, Rigshospitalet, Copenhagen, <sup>5</sup>Faculty of Health Sciences, University of Copenhagen, <sup>6</sup>Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health Sciences, University of Copenhagen, <sup>7</sup>Faculty of Health Sciences, University of Southern Denmark, Odense, <sup>8</sup>Faculty of Health Science, University of Copenhagen, Denmark.

**Background and aims:** YKL-40 is a glycoprotein secreted by a variety of human cell types. YKL-40 is a marker of inflammation and is associated with diabetes, insulin resistance and atherosclerosis. Fetal exposure to intrauterine hyperglycaemia because of maternal diabetes increases the risk of overweight, the metabolic syndrome and type 2 diabetes in the adult offspring. We aimed to investigate associations between exposure to intrauterine hyperglycaemia and plasma level of YKL-40 in adult offspring.

**Materials and methods:** We studied 597 offspring, aged 18–27 years, from 4 different groups based on maternal glycemic status and genetic predisposition to type 2 diabetes: 1. Offspring of women with gestational diabetes mellitus (GDM) 2. Offspring of women with risk factors for GDM but normal glucose tolerance in pregnancy 3. Offspring of women with type 1 diabetes 4. Offspring of women from the background population. The offspring were characterised by fasting plasma levels of YKL-40, and metabolic and anthropometric measurements. Exposure variables were maternal glycaemic status as well as measures of maternal glucose levels during pregnancy.

**Results:** The median plasma YKL-40 in the total cohort was 45 ng/ml (25–75 percentiles: 35–56) without significant differences between the 4 different exposure groups. Multivariate regression analysis did not show an association between maternal glucose level during pregnancy and levels of YKL-40 in the offspring. We found increasing offspring BMI at follow-up (p < 0.0001) to be a positive predictor of YKL-40. Furthermore offspring characterised by overweight (BMI >25kg/m<sup>2</sup>) or the metabolic syndrome (IDF criteria 2006) at follow-up had significantly higher levels of YKL-40 compared with the remaining offspring, (47 vs. 44 ng/ml, p = 0.02 and 49 vs. 44 ng/ml, p = 0.003 respectively).

**Conclusion:** Fetal exposure to intrauterine hyperglycaemia was not associated with levels of YKL-40 in adult offspring of women with diabetes. Adult offspring BMI were positively associated with YKL-40 levels.

## 1084

### Association between small heat shock proteins antibodies and beta cells dysfunction in pregnant women with abnormal glucose tolerance

K.N. Todorova - Ananieva<sup>1</sup>, E.I. Konova<sup>2</sup>, M.A. Atanasova<sup>3</sup>, R.G. Rousev<sup>3,4</sup>, K.V. Petkova<sup>5</sup>, M.G. Genova<sup>6</sup>;

<sup>1</sup>Clinic of Endocrinology, University Hospital, Plevan, <sup>2</sup>Department of Immunology, Clinical Institute of Reproductive Medicine, Plevan, <sup>3</sup>Department of Biology and Immunology, Medical Institute, Plevan, <sup>4</sup>Clinical Institute of Reproductive Medicine, Plevan, <sup>5</sup>Institute of Immunology and Biology of Reproduction, Bulgarian Academy of Science, Sofia, <sup>6</sup>Clinical laboratory and Immunology, University Hospital, Sofia, Bulgaria.

**Background and aims:** The aim of this study was to evaluate the link between serum small heat shock proteins (Hsp) antibodies and changes in  $\beta$ -cell function in pregnant women with normal and abnormal glucose tolerance.

**Materials and methods:** A 75 grams Oral Glucose Tolerance Test (OGTT) was performed on 102 Bulgarian pregnant women in the middle of gestation. According to the results of blood glucose (BG), the patients were divided in three groups: (1) Normal glucose tolerance (NGT; n1=49), (2) Impaired glucose tolerance (IGT; n2=31) and (3) Gestational diabetes mellitus (GDM; n3=22). All pregnant with GDM were negative for anti GAD65 and anti-insulin autoantibodies. The levels of BG were measured in venous plasma at 0min., 60min. and 120min. The levels of immunoreactive insulin (IRI) were measured in serum by ECLIA at 0min. and 60min. and 120min. Circulating sHSP autoantibodies was investigated in sera in all pregnant at 0 min. by using the indirect ELISA. HOMA-B, HOMA-IR and Matsuda-DeFronzo insulin sensitivity index (ISI-M) were used. ANOVA was applied for multiple comparison.

**Results:** The fasting plasma BG, the mean BG and the mean basal insulin values during the OGTT increased progressively among the 3 groups. The stimulating mean levels of IRI measured at 60 min were significantly lower in pregnant with GDM than those levels in pregnant with IGT and with NGT [n3=53.9±30.7  $\mu$ IU/ml vs. n2=65.5±34.17  $\mu$ IU/ml; (P<0.04); and resp. n3=53.9±30.7  $\mu$ IU/ml vs. n1=28.7±23.3  $\mu$ IU/ml; (P<0.001)]. Anti-sHsp antibodies were detected in 5 (16.1%) serum samples of pregnant with IGT and in 12 (54.5%) serum samples from pregnant with GDM, but not found in healthy pregnant. All pregnant with positive circulating sHsp antibodies from g2 and g3 had statistically lower levels of basal and stimulating insulin after glucose loading, compared with those women from the same both groups who were negative for anti sHsp antibodies. HOMA-B in GDM group was significantly lower than HOMA-B in NGT group (n3=99.9 vs. n1=125.4; P<0.001). HOMA-IR was progressively increased from NGT group, to IGT and GDM groups. There is no statistically significant difference in HOMA-B and HOMA-IR between pregnant of group 3 with positive and negative sHsp antibodies. Mean ISI-M was highest in the NGT group (9,18), followed by that in the IGT group (4,3) and then that in the GDM group (4, 04) (overall p<0.0001). The pregnant with GDM positive for sHsp antibodies have had significantly lower mean ISI-M compared with those levels of pregnant with

GDM negative for anti sHsp antibodies [ $2.88 \pm 0.3$  vs.  $3.83 \pm 0.5$ ; ( $P < 0.001$ )]. Multivariate logistic regression analysis have shown independent association of elevated serum anti sHsp antibodies with IGT and GDM.

**Conclusion:** Serum sHsp antibodies are detected in pregnant women with GDM and IGT. They may play a role in pathogenesis of  $\beta$ -cell dysfunction, could be as an immune phenomenon, in relation to ambient insulin resistance.

## 1085

### Circulating sclerostin levels and bone markers in gestational diabetes and physiological pregnancy

E. Ceccarelli<sup>1</sup>, E. Guarino<sup>1</sup>, L. Gennari<sup>2</sup>, D. Merlotti<sup>2</sup>, I. Spagnuolo<sup>1</sup>, M. Dalfrà<sup>3</sup>, R. Nuti<sup>3</sup>, A. Lapolla<sup>3</sup>, F. Dotta<sup>1</sup>;

<sup>1</sup>Diabetes Unit, Department of Endocrine-Metabolic Sciences, Siena,

<sup>2</sup>Department of Endocrine-Metabolic Sciences, Siena, <sup>3</sup>Department of Medical and Surgical Sciences, Padova, Italy.

**Background and aims:** Several studies have highlighted the link between changes in bone metabolism and diabetes, resulting in an increased risk of developing osteoporosis. In patients with type 2 diabetes, increased circulating levels of osteoprotegerin (OPG), an inhibitor of receptor activator of RANKL-mediated osteoclastic bone resorption, and of sclerostin (SOST) have been reported. Sclerostin is a secreted Wnt antagonist produced almost exclusively by osteocytes that binds to the Low-density lipoprotein Receptor related Proteins-5 and -6 (LRP5 e LRP6), thus inhibiting the canonical Wnt/ $\beta$ -catenin signalling pathway and thereby osteoblast activity. Aim of our study was to evaluate circulating levels sclerostin and of bone turnover markers in pregnant women with gestational diabetes subjects and with normal glucose tolerant during pregnancy.

**Materials and methods:** In our study we enrolled pregnant women with gestational diabetes (GDM,  $n=46$ ) and with normal glucose tolerant (NGT,  $n=103$ ) during pregnancy. Serum concentrations of OPG, Osteocalcin (OC), C-telopeptide of type 1 collagen (CTX), 25-OH vitamin D (evaluated by RIA) and SOST (evaluated by ELISA) have been measured in GDM and in NGT between 23rd and 29th week of pregnancy. Sclerostin was measured also in a group of non-pregnant age matched fertile women (CT).

**Results:** No difference was observed between the two groups for age and BMI before pregnancy. Fasting glucose levels in GDM, as expected, were higher than in NGT ( $88 \pm 15$  mg/dl vs  $76.8 \pm 7$ ,  $p=0.02$ ). Circulating SOST levels were similar in GDM ( $13.7 \pm 0.8$  pmol/L) and in NGT ( $13.9 \pm 8.0$  pmol/L), but were significantly lower ( $p < 0.001$ ) when compared to non-pregnant control group CT ( $40.0 \pm 20.0$  pmol/L). Osteocalcin, 25-OH vitamin D and CTX serum levels did not differ between GDM and NGT ( $0.4 \pm 0.6$  ng/ml vs  $0.4 \pm 0.4$ ;  $39 \pm 19$  ng/ml vs  $33 \pm 23$ ;  $0.4 \pm 0.21$  ng/ml vs  $0.4 \pm 0.16$ , respectively). We then divided the GDM group into two subgroups on the basis of therapy: GDM in dietary treatment ( $n = 30$ ) and GDM in insulin treatment ( $n=16$ ). In the insulin treated group, SOST levels positively correlated with BMI before pregnancy ( $r = 0.5$ ;  $p = 0.05$ ). OPG levels in insulin-treated GDM were higher than in GDM treated with diet ( $9.8 \pm 4$  vs  $7 \pm 3$  pmol/l,  $p = 0.02$ ) while OC, CTX and 25-OH vitamin D levels showed no significant difference between the two GDM subgroups.

**Conclusion:** In conclusion, we have uncovered that sclerostin levels are significantly reduced in pregnancy (both GDM and NGT), in agreement with the need to promote foetal skeletal growth; moreover OPG levels are increased in patients suffering from GDM needing insulin treatment, similar to what reported in patients with type 2 diabetes.

## 1086

### The expression of genes involved in NF- $\kappa$ B activation in peripheral blood mononuclear cells of patients with gestational diabetes

B. Telejko<sup>1</sup>, M. Kuzmicki<sup>2</sup>, A. Kretowski<sup>1</sup>, N. Wawrusiewicz-Kurylonek<sup>1</sup>, D. Lipinska<sup>1</sup>, J. Pliszka<sup>2</sup>, J. Wilk<sup>1</sup>, J. Skibinska<sup>1</sup>, A. Zielinska<sup>1</sup>, J. Szamatowicz<sup>2</sup>, M. Gorska<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Diabetology and Internal Medicine,

<sup>2</sup>Department of Gynecology, Medical University of Bialystok, Poland.

**Background and aims:** It has been shown that in patients with obesity and type 2 diabetes the changes in insulin resistance are accompanied by the changes in expression of genes involved in NF- $\kappa$ B activation in peripheral blood mononuclear cells (PBMCs). Since these effects have never been studied in patients with gestational diabetes (GDM), we measured the expression

of genes associated with the activation of NF $\kappa$ B and related to immunological and endothelial function in PBMCs obtained from women with GDM and normal glucose tolerance (NGT) during pregnancy, and assessed its relationship with various indices of insulin resistance.

**Materials and methods:** Real-time PCR was performed with TaqMan chemistry (Applied Biosystems, USA) in 35 women between 24 and 28 week of gestation. All tests were repeated four weeks later and 3 months after child birth.

**Results:** In the 2<sup>nd</sup> trimester the expression of CX3CL1 and interleukin-8 (IL-8) mRNA were significantly higher ( $p=0.02$  and  $p=0.04$ , respectively), whereas IL-17 mRNA expression was lower ( $p=0.02$ ) in the women with GDM than in the subjects with NGT. In the 3<sup>rd</sup> trimester down-regulation of TNFRSF1A ( $p=0.04$ ), PPAR- $\gamma$  ( $p=0.03$ ), STAT3 ( $p=0.02$ ) and CX3CL1 ( $p=0.04$ ) mRNA expression was found in the GDM patients in comparison with the healthy pregnant women. Three months after child birth the expression of IKBK $\beta$  ( $p=0.01$ ) and SLC27A2 ( $p=0.03$ ) mRNA was up-regulated in women with the history of GDM. In patients with NGT both in the 2<sup>nd</sup> and 3<sup>rd</sup> trimester a significant increase in CX3CL1 and STAT1 mRNA expression was observed during 4 weeks ( $p=0.03$ ), whereas in the patients who developed GDM in the 3<sup>rd</sup> trimester, there was a significant decrease in CCL5 ( $p=0.03$ ), IKBK $\beta$  ( $p=0.03$ ), DPP4 ( $p=0.01$ ) and IL-17 ( $p=0.03$ ) mRNA expression in PBMCs. In the group with NGT, IL-10 mRNA expression correlated positively with the insulin secretion-sensitivity index-2 (ISSI-2) ( $R=0.57$ ,  $p=0.03$ ) and negatively with HOMA-IR ( $R=-0.62$ ,  $p=0.02$ ). In the GDM patients STAT3 mRNA expression correlated inversely with the insulinogenic index (IGI) and InsAUC30/GluAUC30 ( $R=-0.61$ ,  $p=0.003$  and  $R=-0.45$ ,  $p=0.03$ , respectively).

**Conclusion:** The changes in the expression of genes encoding immune mediators that are involved in NF $\kappa$ B inflammatory signaling pathways in the PBMCs suggest that immune cells play an essential role in mediating insulin resistance in patients with GDM.

## PS 093 Diagnosis of gestational diabetes mellitus

1087

**How many women with gestational diabetes mellitus are missed if selective screening strategies are used?**

G.E. Avalos, L. Owens, F. Dunne;

School of Medicine, National University of Ireland Galway, Ireland.

**Background and aims:** The number of women with Gestational Diabetes Mellitus (GDM) is increasing in parallel with the increase in the prevalence of obesity worldwide. There is controversy over whether universal or selective screening strategies should be undertaken. The aim of this retrospective study was to establish the number of women proven to have GDM on a universal screening programme that would otherwise have been missed using selective 'risk-factor' based screening and applying either of the American (ADA) European (NICE) or Irish guidelines.

**Materials and methods:** The ATLANTIC Diabetes in Pregnancy (DIP) programme offered universal screening for GDM to pregnant women in Ireland whose last menstrual period was between September 2006 and March 2009. 5,500 women consented and underwent a 75g Oral Glucose Tolerance Test at 24–28 weeks of gestation. The diagnosis of GDM was defined using the WHO criteria. Subsequently the dataset was re-analysed according to the International Association of Diabetes in Pregnancy Study Group [IADPSG] criteria. This dataset was used in the present study and selective screening risk factors were applied using the American Diabetes Association (ADA), National Institute for Health and Clinical Excellence (NICE) and Irish guidelines. The number of risk factors were computed for each participant using the three different guidelines. ADA guidelines: Family History of Diabetes, BMI $\geq$ 25, BP $\geq$ 140/90, and High risk ethnicity. NICE guidelines: Family History of Diabetes, BMI $>$ 30, and High risk ethnicity. Irish guidelines: Family History of Diabetes, BMI $\geq$ 30, Age $\geq$ 40 and High risk ethnicity. The three guidelines provide a list of risk factors however not all the risk factors were included in this study due to lack of information.

**Results:** Out of the 5,500 women who consented to take part in the Atlantic DIP universal screening study, 681 (12%) were diagnosed with GDM according to IADPSG criteria. 101 (16%) women diagnosed with GDM by universal screening had zero risk factors. If a selective screening strategy using Irish guidelines was used these women would have been missed. If a selective screening using the NICE guidelines was used 120 (20%) of women would be missed. Only 33 (5%) women would be missed if using the ADA guidelines.

**Conclusion:** Selective screening based on risk factors misses cases of GDM. Selective screening using 2012 ADA criteria misses fewer women (5%) with GDM. Our results agree with the recommendations of the ADA clinical practice guidelines 2012 that "All women not known to have prior diabetes should undergo a 75g OGTT at 24 to 28 weeks of gestation". If universal screening is not economically possible we should select women based on ADA 2012 selective criteria which includes women with a BMI $\geq$ 25.

**Percentage of risk factors carried by women with GDM

**Implications of the new criteria for diagnosis of gestational diabetes mellitus in Portugal**

J.M. Dores, C. Freitas, Pregnancy and Diabetes Study Group from the Portuguese Society of Diabetology; Endocrinology, Hospital Geral de Santo António, Porto, Portugal.

**Background and aims:** Following the recent recommendations of the International Association of Diabetes and Pregnancy Study Groups, the new criteria for diagnosis of Gestational Diabetes Mellitus (GDM) were adopted in January of 2011 in Portugal. The diagnosis can be established in either the first trimester with a fasting glucose value  $\geq$  92 mg/dl, or between the 24–28 weeks of gestation, using a 75 gr OGTT, in which is necessary to have one or more glucose values  $\geq$  92, 180 or 153 mg/dl at 0', 60' 120', respectively, to fulfill the GDM diagnosis criteria. The authors aimed to evaluate the implications of this change on the burden of their outpatient clinic, as well as the maternal-fetal outcomes.

**Materials and methods:** The authors intended to conduct a retrospective study enrolling all the Portuguese centers with GDM outpatient clinic. The authors gathered the relevant data sent by the centers after a previous invitation to participate in this observational study. The inclusion criteria was all GDM diagnosed women who were admitted in the outpatient clinic between 1<sup>st</sup> April and 30<sup>th</sup> September 2010 (group A) and in the homologous period of 2011 (group B). Both groups were compared using appropriated statistical analyses.

**Results:** Among 39 centers, 22 (56,4%) sent their data. Overall, data from 863 women were eligible for the group A and 1010 for the group B, revealing an increment of 147 cases (17%) from the first to the second group where the new GDM diagnostic criteria was applied. Comparing the 2 groups, there was a significant precocity in the time of diagnosis and referral in the group B (diagnosis at 22,5 vs 28,9 weeks;  $p=0,0001$  and first appointment at 26,3 vs 30,8 weeks;  $p<0,0001$ ). In this group pregnant women achieved less weight gain (10 vs 10,9 Kg;  $p=0,002$ ), were more insulin treated (39,8 vs 28,4%;  $p<0,0001$ ), earlier (27,9 vs 30,6 weeks;  $p<0,0001$ ) and with higher insulin dose (21,8 vs 17,9 UI/day;  $p=0,003$ ). These pregnant women had more hypertension (11,4 vs 7,2%;  $p=0,03$ ) but no preeclampsia, hidramnios or fetal death. They had more preterm delivery (9,5 vs 4,9%;  $p=0,0003$ ), but there were no differences in the type of labor between the two groups, including cesarean delivery (40% in group A vs 36,8% in Group B). Group B newborns had less mean birth weight (3135 vs 3209 gr;  $p=0,003$ ) with less large for gestational age (LGA) (12 vs 15,3 %;  $p=0,04$ ), but no statistical significant difference in macrosomia (4,4 vs 5,2%). There were no differences in the morbid-mortality of the offspring between both groups including the hypoglycemia rate (1,2% in Group A vs 1,6% in Group B). There were less reclassification tests in the group B (53,2 vs 64%) because some of the pregnancies are still in course, with no differences in their results. Nevertheless, in the group B, the results were worst in women diagnosed along the first trimester: less normal reclassification OGTT (76,9 vs 87,9%;  $p=0,003$ ), more impaired fasting glucose (5,2 vs 0,8%;  $p=0,004$ ) and more diabetes (6,7 vs 1%;  $p=0,001$ ).

**Conclusion:** The new criteria for diagnosis of GDM caused a further increment in its incidence and an earlier referral of these pregnant women to the pregnancy and diabetic clinics, so we can expect an increase in their first and second appointments. Pregnant women with GDM diagnosed in the first trimester seem to have a worst metabolic scenario according to the post partum OGTT results. Nevertheless, with an earlier and more aggressive treatment, there seems to have no differences in the outcome of the offspring.

1089

**Potential impact on service provision using different diagnostic criteria for GDM-A retrospective analysis of OGTT data in a London teaching hospital**

S. Sivappriyan<sup>1</sup>, S. Das<sup>2</sup>, D. Patel<sup>1</sup>, J. Modder<sup>2</sup>;

<sup>1</sup>Diabetes, <sup>2</sup>Obstetrics, University College London Hospitals NHS Trust, UK.

**Background:** Gestational Diabetes Mellitus (GDM) is associated with maternal morbidity, adverse perinatal and neonatal outcome and increased risk of type 2 diabetes following the index pregnancy. There is an increasing prevalence of GDM with the obesity 'epidemic'. Although diagnostic criteria for GDM was first established 40 years ago, there is still no consensus on diagnostic threshold values or number of abnormal results required. Internationally there are at least 6 different diagnostic criteria in use. Diagnosing GDM inevitably results in 'medicalisation' of pregnancy and also has resource im-

plications for healthcare commissioners and service providers. UCLH NHS Foundation Trust is a large teaching hospital in London caring for pregnant women with diabetes from varied ethnic and social backgrounds. Since 2003, we have used a three step diagnostic OGTT based on ADA criteria, following universal screening with random plasma glucose at booking and 28 weeks gestation. The International Association of Diabetes and Pregnancy Study Groups (IADPSG) recently published recommendations based on current evidence including the HAPO study. The UK National Institute of Health and Clinical Excellence (NICE) recommends criteria based on WHO recommendations.

**Aims:** Identify the number and proportion of pregnancies diagnosed as GDM using IADPSG, ADA and WHO criteria. Consider the potential resource implications for the diabetes maternity service using IADPSG criteria.

**Materials and methods:** We conducted a retrospective analysis of OGTT data for all women delivering between 1 January and 31 December 2011. We applied three most popular diagnostic criteria for GDM including WHO, ADA and new IADPSG criteria. In case of women who had more than one OGTT antenatally, only last OGTT was included for analysis.

**Results:** There were 5736 deliveries at or after 24+0 weeks between 1 Jan - 31 Dec 2011. A total of 1234 (22%) women had at least one OGTT antenatally. 414 (33 %) women had GDM using any diagnostic criteria. 153 women were diagnosed to have GDM using ADA criteria, 230 women had GDM by WHO criteria and 374 women had GDM by IADPSG criteria. Of these 124 pregnancies had GDM with all three criteria. The prevalence of GDM by ADA, WHO and IADPSG criteria was 2.7%, 4% and 6.5% respectively. In our hospital in 2011, by using ADA criteria we missed 40 GDM pregnancies diagnosed by WHO criteria, 155 GDM pregnancies diagnosed by IADPSG criteria and 66 GDM pregnancies diagnosed by both WHO and IADPSG criteria. While the prevalence of GDM women in 2011 using IADPSG criteria was much less than that in the overall HAPO study (17.8%), 221 additional GDM diagnoses would have been made if we had adopted IADPSG criteria, which represents a 144% increase in the number of GDM cases. This would have had a significant impact on maternity service provision and also long term post pregnancy follow up.

**Conclusion:** Adopting IADPSG criteria will lead to a significant increase in GDM populations. This increased prevalence appears higher than that published by another unit in UK. While IADPSG criteria is based on robust observational data, there is currently a lack of evidence about the effect of intervention on clinical outcomes in GDM diagnosed using IADPSG criteria. We are planning a retrospective comparison of clinical outcomes in the intervened versus non-intervened IADPSG pregnancies.

## 1090

### Gestational diabetes audit

A.I. Palalau<sup>1</sup>, J. Murphy<sup>2</sup>, L. Williams<sup>1</sup>, G. Chana<sup>1</sup>, N. Johns<sup>2</sup>, J. Webber<sup>1</sup>;

<sup>1</sup>Diabetes Centre, Queen Elizabeth Hospital Birmingham, <sup>2</sup>Diabetes Centre, Birmingham Women's Hospital, UK.

**Background and aims:** Gestational Diabetes (GDM) is increasingly being recognised and more at risk patients are being screened; this is likely to lead to an increase in the number of diagnoses. We aimed to quantify the rise in the number of patients diagnosed and managed in our unit and to assess patient and pregnancy outcomes.

**Materials and methods:** We undertook a review of the results of OGTTs (oral glucose tolerance tests) done in our clinic. We conducted a separate case notes review of patients with gestational diabetes who had been managed in our clinic.

**Results:** A total of 2529 OGTTs were performed between April and December 2011 in pregnant women. Out of all OGTTs performed, 254 (10.0%) were diagnostic of GDM. The number of women tested for GDM rose progressively from 215 in April to 426 in December and the number of women diagnosed each month with GDM increased in parallel from 20 in April to 41 in December. We separately identified 379 women diagnosed with GDM between November 2008 and August 2011 and managed in our unit. Most of our patients were of South Asian ethnicity (52.9%) with 27.9% being White Caucasian, 6.1% Arabic and 4.8% African or Afro-Caribbean. The average weight at the diagnosis of GDM was 82.5 kg (range 48.9 to 152.7) and the average BMI 30.2 (range 17.2 to 50.8). During pregnancy, 174 (45.9%) patients were treated by dietary changes alone, 68 (17.9%) were treated with metformin only, 99 (26.1%) with insulin only and 37 (9.8%) with both insulin and metformin. The average weight gain per week from diagnosis of GDM to delivery was 0.165 kg/week (range -0.81 to 1.26 kg/week). In women treated by diet alone, the average weight gain was 0.166 kg/week, in women

treated with metformin alone, 0.119 kg/week, in women treated with insulin alone 0.208 kg/week and in women treated with both metformin and insulin 0.160 kg/week. The average foetal weight at delivery was 3.27 kg (range 1.1–5.6 kg) and was similar in all treatment groups. Pregnancy related complications (including breech presentation, premature rupture of membranes, intrapartum foetal distress, shoulder dystocia and failure to progress in labour) were recorded in 43 (11.3%) of women. The mode of delivery was known for 369 (97.4%) women: normal vaginal delivery in 191 (68.8%) women, assisted vaginal delivery in 39 (10.6%) women and Caesarean section in 139 (37.7%). Out of the women having Caesarean sections, 54 (38.9%) had it as an emergency procedure. Six weeks postnatal OGTTs were performed in 310 (81.8%) of women. Abnormal results were found in 54 (17.4%) of women: 27 (8.4%) had impaired glucose tolerance, 10 (3.2%) had impaired fasting glycaemia, 11 (3.5%) had both impaired fasting glycaemia and impaired glucose tolerance and 6 (1.9%) had diabetes.

**Conclusion:** Out of the total number of pregnant women referred for screening, 10% have an OGTT diagnostic of GDM. After implementation of the NICE screening criteria in our area, the number of monthly OGTTs performed and GDM diagnoses has doubled in less than a year. More than half of our patients with GDM require treatment with metformin, insulin or both during pregnancy. Weight gain in pregnancy is lowest with metformin, intermediate with diet treatment or metformin-insulin combination treatment and highest in patients receiving insulin alone. Most of our patients with GDM have normal vaginal deliveries but more than 1 in 10 women have a pregnancy-related complication. More than 1 in 6 women have abnormal glucose tolerance 6 weeks after delivery with almost 2% having diabetes.

## 1091

### Evaluation of the interest of switching from a systematic screening to a targeted screening of gestational diabetes in a high-risk maternity hospital

S. Jacqueminet<sup>1</sup>, C. Ciangura<sup>1</sup>, A. Dierick-Gallet<sup>1</sup>, O. Bourron<sup>1</sup>, C. Sachon<sup>1</sup>, D. Vauthier-Brouze<sup>2</sup>, J. Nizard<sup>2</sup>, M. Dommergues<sup>2</sup>, A. Hartemann<sup>1</sup>;

<sup>1</sup>Pôle Coeur-Métabolisme, <sup>2</sup>Gynécologie-Obstétrique, Groupe hospitalier Pitié-Salpêtrière, Paris, France.

**Background and aims:** Gestational diabetes (GD) has been systematically screened in our hospital's maternity for 15 years. The 2010 French Guidelines propose a targeted screening in women having at least one of the following risk factors: BMI  $\geq 25$  Kg/m<sup>2</sup>; age  $\geq 35$  years; 1st degree family history of type 2 diabetes; personal GD history; macrosomia history. Our aim was to assess the risk level of the screened population and the potential consequences of implementing a targeted screening.

**Patients and methods:** 2370 women were prospectively followed in our hospital's maternity from September 2010 to August 2011. All the women did an oral glucose tolerance test (OGTT) 75g between 24 and 28 weeks amenorrhea. Prescriptions were given by midwives and obstetricians. Women were asked to fill in an information card, concerning GD risk factors, which was attached to the prescription. The test results with the information cards were sent to the diabetologist (GD diagnostic; IADGSP 2010 criterion)

**Results:** 1782 (75%) cards with OGTT data were received; 1209 cards (68%) were fully filled in, corresponding to: (i) 557 (46%) women without any risk factors, of whom 40 (7%) had a GD; and (ii) 652 women (54%) with at least one risk factor, of whom 190 (29%) had a GD. Amongst those 652 women the risk factors identified were: 316 (48.4%) women had a BMI  $\geq 25$  Kg/m<sup>2</sup>; 328 (50.6%) had an age  $\geq 35$  years; 228 (35%) had a 1st degree family history of type 2 diabetes; 47 (7.2%) had personal GD history; 39 (6%) had a macrosomia history in a previous pregnancy. Out of the 230 women with GD 17% had no risk factors and 83% had at least one risk factor.

**Conclusion:** Our population had a strong prevalence of GD risk factors. After discussion with the maternity team we decided to maintain systematic screening of GD. The procedure, which has been set up between the maternity and our department, is now efficient. This procedure enabled a low rate of macrosomia (5%) to be obtained as shown by a recent data analysis. A change in practice could disorganize our collaboration with the maternity, resulting in a loss of completeness in the screening of gestational diabetes in women at risk. Moreover, the percentage of women without any risk factors yet having GD is not negligible.

## 1092

### Evaluation of the results of a universal GDM screening according to both WHO and IADPSG criteria

A. Kun<sup>1</sup>, A.G. Tabak<sup>2,3</sup>, Z. Sudar<sup>4</sup>, J. Tornoczy<sup>5</sup>, P. Vargha<sup>6</sup>, Z. Kerenyi<sup>7,8</sup>, G. Tamas<sup>2,8</sup>,

<sup>1</sup>Department Obstetrics and Gynecology, Tolna County Balassa Janos Hospital, Szekszard, Hungary, <sup>2</sup>1st Department of Medicine, Semmelweis University, Budapest, Hungary, <sup>3</sup>Department of Epidemiology and Public Health, University College London, UK, <sup>4</sup>3rd Department Internal Medicine, Tolna County Balassa Janos Hospital, Szekszard, Hungary, <sup>5</sup>Diabetes Care Outpatient Unit, Tolna County Balassa Janos Hospital, Szekszard, Hungary, <sup>6</sup>Department of Cardiology, Semmelweis University, Budapest, Hungary, <sup>7</sup>Diabetology, Tóth Ilona Health Service, Budapest, Hungary, <sup>8</sup>National Centre for Diabetes Care, Semmelweis University, Budapest, Hungary.

**Background and aims:** Based on the HAPO study results, IADPSG recommended new diagnostic criteria for diabetes (GDM) in 2010. To better understand risk factors and describe the frequency of GDM a universal screening was performed using the WHO criteria in 3 representative regions of Hungary in 2007–2009. While the prevalence of GDM significantly increased in the multinational HAPO study, no similar estimates are available regarding the epidemiology of GDM in Hungary.

**Materials and methods:** Between 15th May 2010 and 14th May 2011 all pregnant women in the Szekszárd region (South West Hungary) were invited for a 3-point 2-hour oral glucose tolerance test (fasting glucose, 1-h and 2-h glucose). Results were evaluated according to both the WHO and the IADPSG criteria, while intervention was initiated only in women diagnosed by the WHO recommendation.

**Results:** Among 1080 pregnant women (age:  $29.6 \pm 5.4$  yrs [mean  $\pm$  SD], BMI at booking:  $25.6 \pm 6.0$  kg/m<sup>2</sup>) screened, GDM was found in 81 (7.5%) cases based on the WHO criteria and in 177 women (16.4%) based on the IADPSG criteria. GDM women irrespective of the diagnostic criteria used, were older ( $31.4 \pm 5.5$  vs.  $29.4 \pm 5.4$  yrs [WHO];  $P=0.0016$ ;  $30.9 \pm 5.3$  vs.  $29.4 \pm 5.4$  yrs [IADPSG];  $P=0.0004$ ), had higher systolic blood pressure ( $124 \pm 10$  vs.  $121 \pm 11$  mmHg; [WHO];  $P=0.028$ ;  $123 \pm 11$  vs.  $121 \pm 11$  mmHg [IADPSG];  $P=0.021$ ). Only 55 women were diagnosed by both diagnostic criteria with GDM. According to the IADPSG criteria 26 of the WHO-GDM cases had normal glucose tolerance and 122 additional IADPSG-GDM cases were diagnosed that were normoglycemic based on the WHO criteria. The WHO-GDM only and the IADPSG-GDM only cases had similar age ( $P>0.05$ ) however the latter group had a higher BMI ( $24.9 \pm 4.7$  vs.  $27.6 \pm 5.3$  kg/m<sup>2</sup>;  $P=0.016$ ). Caesarean section rates were similar in all groups such as the frequency of intrauterine deaths and congenital malformations. Babies born to IADPSG-GDM only mothers (without any intervention) were heavier compared to that of healthy women ( $3459 \pm 541$  vs.  $3327 \pm 502$  g;  $P=0.018$ ).

**Conclusion:** According to our results, it is expected that the frequency of GDM would double if the new IADPSG criteria were utilized in Hungary. While the increased birth weight of the IADPSG-only women supports the use of the new diagnostic criteria, the application of the IADPSG diagnostic criteria certainly requires substantial changes of the current care of pregnant women.

## 1093

### Screening of gestational diabetes in Italy: searching for the best way to diagnose it

E. Lacaria<sup>1</sup>, G. Di Cianni<sup>2</sup>, V. Resi<sup>1</sup>, A. Ghio<sup>1</sup>, C. Lencioni<sup>2</sup>, C. Goretti<sup>2</sup>, C. Sannino<sup>2</sup>, S. Del Prato<sup>1</sup>, A. Bertolotto<sup>1</sup>;

<sup>1</sup>Department of Endocrinology and Metabolism, Section of Diabetes and Metabolic Diseases, University of Pisa, <sup>2</sup>Department of Diabetes and Metabolic Diseases, Hospital of Livorno ASL6, Livorno, Italy.

**Background and aims:** The debate regarding the utility of universal screening for diagnosis of gestational diabetes (GDM) is real and continues to generate lively discussion, especially regarding expenditure of health resources. In Italy, universal GDM screening was based on Carpenter and Coustan's criteria till March 2010, when the International Association of Diabetes and Pregnancy Study Groups (IADPSG) recommendations were adopted leading to an immediate increase in GDM diagnosis. This increase has generated some alarm and in September 2011 the Italian Public Health Ministry recommended GDM screening only for women with risk factors. The aim of the present study was to compare GDM prevalence calculated according to different diagnostic procedures in the Italian population.

**Materials and methods:** We compared two groups of Caucasian pregnant women from the Tuscany region who have been screened for GDM according to different diagnostic criteria. Group A consisted of 3950 women undergoing universal screening based on Carpenter and Coustan's criteria during the years 2001–2003. Group B included 2274 women undergoing universal screening according to the IADPSG criteria in the years 2010–2011. The two groups were comparable for clinical and anthropometric features. Finally we have retrospectively re-evaluated GDM prevalence applying the IADPSG criteria only on Group B women deemed at GDM risk because of personal history of GDM; pre-pregnancy BMI  $\geq 25$  Kg/m<sup>2</sup>; fasting plasma glucose at the first visit 100–125 mg/dl; age  $\geq 35$  years; previous macrosomia; family history of diabetes.

**Results:** As compared to Carpenter and Coustan's, universal screening by IADPSG criteria resulted in a significant increase of the prevalence of GDM ( $P<0.04$ ). Applying IADPSG criteria only in women deemed at risk GDM marginally reduced the calculated prevalence of GDM, which remained ( $p<0.09$ ) higher as compared to the one obtained with Carpenter and Coustan's criteria.

**Conclusion:** Adoption of the IADPSG criteria is associated with a significant increase in GDM prevalence. Limiting screening in high risk women still results in significantly higher GDM prevalence. Therefore, recommendations not to test low-risk group women, in order to limit costs for the Public Health System, are dubious and require further examination.

\*In Group B (n 2274) we have identified 1887 women (83%) with at least one risk factor for GDM

	Universal Screening 2001–2003	Universal Screening 2010–2011	Selective Screening 2010–2011
Type of screening	Carpenter and Coustan GCT (50g)+OGTT(100g)	IADPSG FPG $\geq 92$ mg/dl or Ministry OGTT(75g)	Italian Health Ministry OGTT(75g)

## 1094

### Evaluation of the French guidelines for a selective screening of gestational diabetes mellitus from a cohort of 18770 women over 9 years

E. Cosson<sup>1</sup>, I. Pharisien, A. Benbara, Y. Jaber, B. Lormeau, D. Sandre-Banon, N. Assad, C. Cussac Pillegand, P. Valensi, L. Carbillon;

<sup>1</sup>AP-HP, Jean Verdier Hospital, Bondy, France

**Background and aims:** We aimed to evaluate the French societies of Diabetology and Obstetric 2010 guidelines to selectively screen for gestational diabetes mellitus (GDM), based on body mass index  $\geq 25$  kg/m<sup>2</sup> (BMI25) or age  $\geq 35$  years (age35) or family history of diabetes (FamDiab) or personal history of GDM (PrevGDM) or macrosomia (PrevMacro).

**Materials and methods:** We selected from all deliveries between 2002 and 2010 in our university hospital located in a suburb of Paris, France (n=20630,  $29.7 \pm 5.8$  years old, BMI  $24.1 \pm 4.9$  kg/m<sup>2</sup>, hypertension 2.2%, women from Europe 57%, North Africa 27%, Africa 22%) the 18.770 women with no known diabetes and for whom all risk factors (RF) were known. During this period, GDM was universally screened and defined as fasting plasma glucose level  $\geq 5.3$  mmol/l and/or 2 hour post-load (75g) glucose level  $\geq 7.8$  mmol/l.

**Results:** The prevalence of at least 1 risk factor (" $\geq 1$ RF") increased between 2002 and 2010 (51.7 to 61.5%,  $p<0.001$ ) with no change in GDM prevalence (mean 14.8%, intention to screen). Each RF was significantly associated with GDM, with odds ratio ranging from 1.1 (BMI25, age35, FamDiab) to 1.25 (PrevGDM) and 5.9 (PrevMacro); and the odds ratio for " $\geq 1$ RF" was 1.4 [95%CI 1.3–1.5],  $p<0.001$ ). Overall, 58.5% of women had  $\geq 1$ RF and would have been screened if the guidelines had been followed; and 34.7% of the GDM would have been missed. The presence of " $\geq 1$ RF" added prognostic value to the presence of GDM for new onset of hypertension or preeclampsia, large for gestational age, need for hospitalization during pregnancy and elective caesarean section ( $p<0.001$  for all).

**Conclusion:** The presence of  $\geq 1$ RF is predictive of GDM and its prevalence increases. However, the sensitivity of selective screening is 65.3%. Although the women with both GDM and  $\geq 1$ RF were more often hospitalized and had more elective caesarean sections, they had more preeclampsia and large for

gestational age babies. Therefore, selective screening as recommended in France is not sensitive enough, but detects the women with the highest risk of GDM complications. These data remain to be checked using the new diagnostic criteria.

## 1095

### The effect of gestational diabetes mellitus (GDM) on maternity care and costs in Ireland

P. Gillespie<sup>1</sup>, C. O'Neill<sup>1</sup>, J. Cullinan<sup>1</sup>, F. Dunne<sup>2</sup>;

<sup>1</sup>School of Business and Economics, <sup>2</sup>School of Medicine, Galway, Ireland.

**Background and aims:** Given the increasing prevalence of GDM, as well as its potentially serious implications for maternal and neonatal outcomes, a literature has emerged which examines the economic impacts of GDM. This study explores the independent effects of GDM on maternity care and costs in Ireland, over and above the effects of other potentially important risk factors.

**Materials and materials:** Prospective analysis of 4372 women in the Irish ATLANTIC DIP Study between 2007 and 2009 who had a 75-g oral glucose tolerance test at 24–28 weeks during their pregnancy. Mode of delivery was recorded as normal vaginal delivery (NVD), assisted vaginal delivery (forceps and/or ventouse) (AVD), elective caesarean section (ELCS), and emergency caesarean section delivery (ERCS). Neonatal unit admission was recorded as whether or not an infant was admitted for neonatal intensive care. Unit cost estimates (Euros in 2010 prices) were applied to value resource use (€2417 per NVD case, €3599 per AVD case, €6033 per ELCS case, €7518 per ERCS, and €7528 per neonatal admission). Multinomial logistic, logistic, and generalised linear model multivariate regression analysis was used to explore the effects of GDM and other independent variables (age, body mass index, primiparous, family history of diabetes, previous miscarriage, ethnicity, and delivery week) on three dependent variables: mode of delivery, neonatal unit admission, and costs.

**Results:** Using the International Association of Diabetes and Pregnancy Study Group criteria (fasting blood glucose >5.1 mmol/l, 1-h value >10 mmol/l, and 2-h value >8.5 mmol/l), a total of 354 women or 8.1% had a positive GDM diagnosis. Mode of delivery for non-GDM cases consisted of 64.9% for NVD, 18.3% for AVD, 8.5% for ELCS, and 8.4% for ERCS. This compared to 59.5%, 15.1%, 13.7% and 11.8% respectively for GDM cases. After controlling for other factors, the odds ratio for an ERCS relative to a NVD was 1.75 (95% CIs: 1.08, 2.81,  $P < 0.05$ ) for GDM relative to non-GDM cases. Neonatal unit admission for non-GDM cases was 10.42% compared to 28.70% for GDM cases. After controlling for other factors, the odds ratio for a neonatal admission was 3.14 (95% CIs: 2.27, 4.34,  $P < 0.01$ ) for GDM relative to non-GDM cases. The mean cost per non-GDM case was €4117 (SD: 3019) compared to €6039 (SD: 4378) per GDM case. After controlling for other factors, the incremental cost per GDM case was €1597 (95% CIs: 1086, 2108,  $P < 0.01$ ).

**Conclusion:** GDM was associated with significant effects on maternity care and costs over and above the effects of other potentially important factors including overweight or obesity during pregnancy. In particular, GDM was associated with higher levels of emergency caesarean section and neonatal unit admission, which translated into higher maternity care costs overall.

Variable /Model	Model 1 Mode of Delivery				Model 2 Neonatal Admission	Model 3 Total cost (€)
	Odds Ratios (SE)				Odds Ratios (SE)	Beta (SE)
	NVD (reference)	AVD	ELCS	ERCS

## 1096

### The diagnosis of gestational diabetes mellitus in women submitted to Roux-in-Y gastric bypass

C. Freitas, M. Monteiro, G. Rocha, D. Seabra, M. Nora, C. Araújo;

Centro Hospitalar Entre Douro e Vouga, Santa Maria da Feira, Portugal.

**Background and aims:** Surgical treatment of severe obesity is growing worldwide and Roux-en-Y gastric bypass is one of the most common bariatric surgeries performed. Almost half of all the patients submitted to this treatment, are women in fertile age. Several series of well succeeded pregnancies have been published. Overall, there are few serious complications and the classical obesity related comorbidities seem to improve, including the incidence of Gestational Diabetes Mellitus (GDM). Following the recent recommendations of the International Association of Diabetes and Pregnancy Study Groups, the new criteria for diagnosis GDM were adopted in January of 2011 in Portugal. Until 2011, women were screened with the O'Sullivan test. When positive, they performed a 100 gr Oral Glucose Tolerance Test (OGTT) and needed to have 2 altered values to establish the diagnosis. After January of 2011, pregnant women are screened in the first trimester with a fasting glucose value, or between 24–28 weeks of gestation, with a 75 gr OGTT, in which only one glucose value of is necessary to fulfill the GDM diagnosis criteria. One of the aims of these criteria is to uniform the diagnosis. Nevertheless, people who have been submitted to gastric surgery shouldn't perform a OGTT. The authors intended to compare the prevalence of GDM in pregnant women submitted to gastric bypass before and after the introduction of these universal diagnosis criteria.

**Materials and methods:** We conducted a retrospective study based on the clinical data of all the pregnant women submitted to gastric bypass referred to the Obstetric outpatient clinic between 2004 and 2011.

**Results:** There were 33 pregnancies, 18 until the end of 2010 with no diagnosis of GDM and 15 after January of 2011, including one abortion and a woman with type 1 diabetes. Applying the new diagnosis criteria to the other 13 women, there were 7 diagnosis of GDM (53.8%), all established with the 60 minutes' glucose value in the OGTT, at  $25 \pm 2.3$  weeks of gestation. Reviewing all the TTOG performed ( $n=19$ , 7 with 100 gr, 12 with 75 gr) we found the same glycemic profile: in the first group glycemic values of 70,8 - 183,5 - 80,3 - 58,8 gr/dl at 0 - 60 - 120 - 180 minutes; in the second values of 71,5 - 173 - 59,3 mg/dl at 0 - 60 - 120 minutes respectively. Eleven of the women who performed a TTOG experimented an hypoglycemia (57,9%). All of the pregnant women with GDM had an excellent metabolic control, despite 2 of them needing 8 UI of intermediate acting insulin at bedtime. Comparing the outcome of these pregnancies and the ones of the women who didn't have GDM, we didn't find any statistical difference. Nevertheless the first ones tended to be older at the time of the gastric bypass (31 vs 28,6 years) and the pregnancy (33,3 vs 30,4 years). Despite having passed more time since the surgery (27,7 vs 19,9 months), women with GDM lost less weight (27,8 vs 40,4 Kg) and had higher Body Mass Index (BMI) at the onset of the pregnancy (30,4 vs 27,4 Kg/m<sup>2</sup>). There were no differences in the outcomes of the pregnancies between the 2 groups.

**Conclusion:** The new criteria for diagnosis of GDM can't be applied to women submitted to gastric bypass for 2 main reasons: first the absorption of an oral glucose load is altered after a gastric surgery and thus, the recommended values can't be applied; second, there is an unacceptable incidence of hypoglycemia directly caused by that glucose load. More studies are needed to support some evidence to apply other tests for the diagnosis of GDM in these women.

## PS 094 Lessons from microvascular cohort studies

### 1097

#### Prevalence and correlates of complicated diabetes mellitus and associated co-morbidities among Sri Lankan adults: the Sri Lanka diabetes and cardiovascular study

P. Ranasinghe<sup>1</sup>, R. Jayawardena<sup>2</sup>, G.R. Constantine<sup>2</sup>, M.H.R. Sheriff<sup>2</sup>, D.R. Matthews<sup>3</sup>, P. Katulanda<sup>2</sup>;

<sup>1</sup>Department of Pharmacology, Faculty of Medicine, Colombo, Sri Lanka,

<sup>2</sup>Diabetes Research Unit, Department of Clinical Medicine, Faculty of Medicine, Colombo, Sri Lanka, <sup>3</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, UK.

**Background and aims:** Diabetes is a leading cause of morbidity and mortality in the world. South Asians are known to be at a higher risk of developing diabetes and have differential risk factors. They are also known to have an earlier onset and a more aggressive progression of the disease than other ethnic groups. We evaluated the prevalence and correlates of microvascular complications and other cardio-metabolic co-morbidities among Sri Lankan adults with diabetes.

**Materials and methods:** This community-based cross-sectional national study on diabetes was conducted in seven of the nine provinces in Sri Lanka between years 2005–2006. Diabetes was diagnosed according to the American Diabetes Association and World Health Organization criteria. Presence/absence of diabetic retinopathy was determined by standardized expert ophthalmological examination. Nephropathy was defined as the presence of micro-/macro- albuminuria, or by perusal of medical records. Neuropathy was diagnosed according to the validated Toronto Clinical Scoring System. Data on physical activity were collected using the short version of the International Physical Activity Questionnaire. Metabolic syndrome was diagnosed based on International Diabetic Federation criteria. Abdominal obesity was defined as waist circumference (WC) > 90 cm in males and > 80 cm in females. Data were analysed using SPSS v15, in all analyses a  $p < 0.05$  was considered statistically significant.

**Results:** Sample size was 4,485 (Response rate-89.7%), 39.5% ( $n=1,772$ ) were males and 17.6% ( $n=789$ ) were residing in urban areas. Mean age was  $46.1 \pm 15.1$  years. The age- and sex-adjusted prevalence of Diabetes, Impaired Glucose Tolerance and Impaired Fasting Glucose were 10.3% (males:9.8%, females:10.9%,  $p < 0.001$ ), 5.4% (males:4.2%, females:6.5%) and 4.4% (males:5.6%, females:3.1%) respectively. The prevalence of micro-vascular complications in diabetic patients were; retinopathy-24.1% (males:27.6%, females:22.6%), nephropathy-4.3% (males:4.1%, females:4.3%) and neuropathy-44.8% (males:44.0%, females:45.2%). Majority had at least one complication (47.2%), 28.6% had two complications, while 20.9% had none of the microvascular complications. In those with diabetes, central obesity was present in 53.2% (males:40.0%, females:61.0%,  $p < 0.001$ ). Prevalence of Metabolic Syndrome was 73.3% (males:64.0%, female:78.9%,  $p < 0.001$ ), while hypertension was present in 55.0% (males:55.3%, females:55.1%). There were no significant differences observed in mean values of weight, BMI, waist circumference, hip circumference, WHR, BP, FBG, 2-hr PPBS, LDL, HDL and total cholesterol in those with and without microvascular complications. In diabetic patients with co-morbid hypertension, metabolic syndrome or obesity the mean FBG, 2-hr PPBS, BMI, waist circumference, systolic BP and diastolic BP was higher than those without co-morbidities.

**Conclusion:** Diabetes is common among Sri Lankan adults, with a high prevalence of microvascular complications and associated co-morbidities. There is an urgent necessity for public health and clinical interventions to tackle the ongoing epidemic.

### 1098

#### Development and progression of diabetes related co-morbidities in patients with type 1 diabetes: the JEVIN trial - a 20 year follow-up

T. Heller<sup>1</sup>, N. Müller<sup>1</sup>, C. Kloos<sup>1</sup>, R. Schiel<sup>2</sup>, I.S. Ross<sup>3</sup>, G. Wolf<sup>1</sup>, U.A. Müller<sup>1</sup>;

<sup>1</sup>Internal Medicine III, University Hospital Jena, Germany, <sup>2</sup>Clinic for Diabetes and Metabolic Diseases, MEDIGREIF Inselklinik Heringsdorf, Germany, <sup>3</sup>University of Aberdeen, UK.

**Background and aims:** In 1989/90 the JEVIN-Trial started as a cross-sectional survey on the quality of diabetes care of insulin treated patients with diabetes type 1 and 2 ( $n=190$ ; age 16–60y). Every 5 years, the cohort was analysed. In 2004/05 and 2009/10 only patients with type-1-diabetes were examined. Since the beginning of the trial enormous changes in social structure and medical care and therapy have occurred. The health care system was decentralised in 1989/90 and structured treatment, as well as teaching programmes for intensified insulin therapy were established. Since 1995, when privately run specialised diabetes out-patient care was established, human insulin replaced animal insulin, insulin analogues were introduced, insulin pump therapy was implemented and multiple daily blood glucose controls became standard. The aim of the investigation was to detect the development and progression of retinopathy, nephropathy and peripheral neuropathy.

**Materials and methods:** Of 131 patients with type 1 diabetes analysed in 1989/90, 104 (79.4%) patients were still alive in 2009/10. Of the living population 83 (79.8%) patients could be identified and of these 73 (88%) patients were examined: women 33%, age 58.5y, diabetes duration 35.2y (20–68), BMI 26.64kg/m<sup>2</sup>, blood pressure 143/82mmHg, HbA<sub>1c</sub> 6.9 (HbA<sub>1c</sub> is DCCT adj.).

**Results:** Seventy percent ( $n=51$ ) of the 73 patients with 20y follow up had no retinopathy at baseline. In 2009/10 still 27% ( $n=20$ ) remains having no retinopathy whereas 51% ( $n=37$ ) had non-proliferative and 18% ( $n=13$ ) proliferative retinopathy. At last observation 32% ( $n=17$ ) had retinal laser treatment. HbA<sub>1c</sub> in patients without/with retinopathy was 7.3%/7.6% (56.3mmol/mol / 59.6mmol/mol; n.s.) at baseline and 6.5%/7.0% (47.5mmol/mol / 53.1mmol/mol; n.s.) at follow up. At baseline 86% ( $n=63$ ) of the patients were free of neuropathy compared to 56% ( $n=41$ ) at follow up. Diabetic foot syndrome (ulcer/gangrene) was prevalent in 3 patients at baseline and in 3 patients at follow up. No amputations were present at baseline but in 2 patients at follow up. HbA<sub>1c</sub> in patients without/with neuropathy was 7.3%/8.1% (56.3mmol/mol / 65.0mmol/mol; n.s.) at baseline and 6.7%/7.1% (49.7mmol/mol / 54.1mmol/mol; n.s.) at follow up. Tests of sensibility were without pathological findings in 45% ( $n=33$ ) and the peripheral pulse status in 70% ( $n=51$ ). No diabetes related nephropathy was present in 77% ( $n=56$ ) in 1989/90 and 49% ( $n=36$ ) at follow up. HbA<sub>1c</sub> in patients without/with nephropathy was 7.4%/7.5% (57.4mmol/mol / 58.5mmol/mol; n.s.) at baseline and 6.8%/7.1% (50.8mmol/mol / 54.1mmol/mol; n.s.) at follow up.

**Conclusion:** After a mean diabetes duration of 35 years and a follow-up of 20 years diabetes related retinopathy increased in prevalence from 30% to about 70% (40%, 2%/y.) compared to 1989/90. In the same period neuropathy increased from 14 to 66% (42%, 2%/y.) whereas the prevalence of nephropathy rose from 23% to 51% (28%, 1.4%/y.). Patients without complications had a lower HbA<sub>1c</sub> at baseline and follow up, but it was not significant. The increase in prevalence is low in comparison to the long follow-up period.

### 1099

#### Impact of HbA<sub>1c</sub> followed from diagnosis on retinopathy and nephropathy in patients with onset of type 1 diabetes before 35 years

H.J. Arnqvist<sup>1</sup>, M. Nordwall<sup>2</sup>, M. Fredriksson<sup>3</sup>, M. Dhir<sup>4</sup>, M. Abrahamsson<sup>4</sup>, J. Ludvigsson<sup>2</sup>, The VISS study group;

<sup>1</sup>Diabetes and Endocrinology, Clinical and experimental medicine,

<sup>2</sup>Pediatrics, <sup>3</sup>Linköping Academic Research Centre, Linköping University,

<sup>4</sup>Ophthalmology, Vrinnevi Hospital, Sweden.

**Background and aims:** HbA<sub>1c</sub> was introduced in diabetes care in the early 80's. HbA<sub>1c</sub> is related to diabetic complications but it is still controversial what HbA<sub>1c</sub> level to aim for in treatment of type 1 diabetes. Our aim was to study the impact of HbA<sub>1c</sub> followed from onset of diabetes, on the incidence and prevalence of retinopathy and nephropathy in an unselected population of patients with type 1 diabetes.

**Materials and methods:** All 480 patients diagnosed with type 1 diabetes before the age of 35 years during 1983–1987 in a region of South East Sweden were followed 20–25 years. Retinopathy was evaluated by fundus photography and albuminuria/nephropathy data were collected from medical records. Long term weighted mean HbA<sub>1c</sub> was calculated.

**Results:** Only 13% had no signs of retinopathy. The prevalence of lower grades of simplex retinopathy was 33%, more severe simplex retinopathy 41% and proliferative retinopathy 13%. Long term mean HbA1c was 55, 63, 69 and 78 (range 57–103) mmol/mol in these groups. The median time to first sign of retinopathy was longer in patients with long term HbA1c  $\leq$  56 mmol/mol compared to patients with long term HbA1c  $\geq$  78 mmol/mol, 17.7 and 11.4 years, respectively ( $p < 0.001$ ). The prevalence of microalbuminuria was 11% and macroalbuminuria 3%. Long term mean HbA1c was 71 mmol/mol and 86 mmol/L (range 68–110) mmol/mol in these groups compared to 65 mmol/mol in patients with no signs of nephropathy ( $p < 0.001$ ).

**Conclusion:** There is a strong association between long term mean HbA1c from diagnosis and development of microvascular complications. Long term mean HbA1c around 55 mmol/mol or lower seems to prevent proliferative retinopathy and nephropathy.

## 1100

### Insulin antibodies are associated with unstable plasma glucose levels and diabetic retinopathy in subjects with type 2 diabetes mellitus

K. Takahashi, M. Ono, M. Matsui, T. Sasai, T. Takahashi, H. Homma, T. Kajiura, H. Taneichi, N. Takebe, J. Satoh;  
Department of Diabetes and Metabolism, Iwate Medical University, Morioka, Japan.

**Background and aims:** The clinical significance of insulin antibodies (IA) cannot be ignored, even after the introduction of either recombinant human or analog insulin. Previous studies have suggested associations of IA with hypoglycemia and hyperglycemia. Furthermore, in a recent study, elevated fasting insulin in the presence of IA was found to be an independent risk factor for CHD in insulin-treated adults. Interpretation of these adverse events has, however, often been limited by a lack of controlled observations and small sample sizes. Herein, we endeavored to ascertain the clinical features of IA-positive type 2 diabetic subjects treated with recombinant human or analogue insulin.

**Materials and methods:** The subjects were inpatients at our university. The study groups consisted of 72 females and 117 males, with a mean age of  $57 \pm 17$  yrs, diabetes duration of  $12 \pm 9.8$  yrs, and HbA1c of  $13 \pm 2.1\%$ . IA levels were measured employing RIA kits for IA with reduced non-specific bindings (Yamasa Co, Tokyo, Japan.) This study was conducted in accordance with the Declaration of Helsinki. Differences in variables between groups were compared by the Mann-Whitney U test. Multiple linear regression analyses were performed to evaluate the combined effects of factors associated with IA.

**Results:** Forty-nine of 105 subjects (46.7%) receiving current or previous therapy with recombinant human or analogue insulin were IA positive (percent binding  $14 \pm 23\%$ ), whereas all of those without ( $n=84$ ) such therapy were IA negative. Among the subjects treated with insulin, those with IA had significantly higher daily insulin requirements ( $37 \pm 23$  vs  $28 \pm 21$  U/ day,  $P=0.043$ ), longer diabetes duration ( $17 \pm 8.8$  vs  $11 \pm 9.6$  yrs,  $P=0.001$ ), longer duration of insulin therapy ( $7.3 \pm 4.9$  vs  $2.4 \pm 4.5$  yrs,  $P=0.001$ ), lower fasting serum C-peptide (CPR) levels ( $1.2 \pm 1.3$  vs  $2.0 \pm 1.6$  ng/ml,  $P=0.024$ ) and higher M-values ( $53 \pm 60$  vs  $35 \pm 36$ ,  $P=0.041$ ), an index of plasma glucose control, than those without IA. Multiple regression analyses revealed that treatments with protaminated insulin ( $\beta=0.318$ ,  $P=0.001$ ), and with regular insulin ( $\beta=-0.259$ ,  $P=0.006$ ) significantly predicted percent binding with IA. This rate was found to be a unique explanatory variable for M-values ( $\beta=0.381$ ,  $P=0.003$ ), whereas fasting serum CPR levels were not. Interestingly, diabetic retinopathy was predicted by the percent binding with IA ( $\beta=0.255$ ,  $P=0.006$ ), but not by M-values.

**Conclusion:** The present study demonstrated that IA may cause unstable plasma glucose levels in type 2 diabetic subjects maintained on recombinant human or analogue insulin therapy. The subjects positive for IA showed significantly lower fasting CPR levels, which, however, seemed rather unlikely to lead to brittleness. Therapy with protaminated insulin was positively associated with the emergence of IA, which could be interpreted, based on a previous observation, as indicating that protaminated proteins had potentiated antigenicity. To our knowledge, this is the first report showing a positive correlation between percent binding with IA and diabetic retinopathy. The mechanism is not associated with unstable plasma glucose levels, and should be further investigated. In conclusion, we propose that the emergence of IA and its concomitant adverse effects should be taken into account, when starting insulin therapy in subjects with type 2 diabetes.

## 1101

### High regression rate of macroalbuminuria may be obtained from intensive blood pressure and blood glucose controls in type 2 diabetes: a 5-year observational cohort study

H. Yokoyama<sup>1</sup>, J. Honjo<sup>1,2</sup>, M. Okuda<sup>1</sup>, S. Kanno<sup>1</sup>, H. Sone<sup>1,3</sup>, S. Okizaki<sup>1,4</sup>, T. Moriya<sup>4</sup>, M. Haneda<sup>2</sup>;

<sup>1</sup>Internal Medicine, Jiyugaoka Clinic, Obihiro, <sup>2</sup>Asahikawa Medical University, <sup>3</sup>University of Tsukuba Institute of Clinical Medicine, Mito, <sup>4</sup>Kitasato University School of Medicine, Sagami-hara, Japan.

**Background and aims:** Individuals suffering from diabetic nephropathy are feared by a progressive increase in albuminuria with relentless decrease in glomerular filtration rate (GFR). It still remains unclear how the progression is inhibited by intensive treatments for blood pressure and blood glucose.

**Materials and methods:** Subjects were recruited consecutively from patients with type 2 diabetes who visited an outpatient clinic in 2002–2008 ( $n=2500$ ) who met the following criteria; macroalbuminuria (urinary albumin-to-creatinine ratio  $\geq 300$  mg/gCr) with eGFR  $\geq 30$  ml min<sup>-1</sup> 1.73 m<sup>-2</sup> at the first visit, and were treated for more than one year. Among the overall patients 211 subjects were eligible for this observational cohort study. The aims of treatment were SBP  $< 130$  mmHg and HbA1c (NGSP)  $< 6.9\%$ . Subjects were followed until the onset of end-stage renal disease (ESRD) or end of follow-up.

**Results:** The mean follow-up period was 4.5 years. After one-year treatment, SBP and HbA1c levels were decreased (from  $147 \pm 21$  to  $131 \pm 16$  mmHg and from  $9.17 \pm 1.11$  to  $7.46 \pm 1.34\%$ ,  $p < 0.0001$  for both, respectively). Simultaneously, the ACR and eGFR levels were decreased (from 816 (IQR 463–1530) to 391 (122–1061) mg/gCr and from  $71.9 \pm 24.9$  to  $63.7 \pm 23.7$  ml min<sup>-1</sup> 1.73 m<sup>-2</sup>,  $p < 0.0001$  for both, respectively). Percentage of subjects whose ACR regressed to  $< 300$  mg/gCr was 47% at 1-year and it persisted to 52% at 5-year. Cumulative incidences of ACR  $< 300$  and  $< 30$  mg/gCr at 5-year were 45% (95%CI 38–52%) and 12% (95%CI 7–19%). Subjects with one-year SBP and HbA1c levels lower than the median levels had more than three-times higher rate of regression to ACR  $< 300$  mg/gCr than those with both levels greater than the median levels ( $p < 0.001$ , Table). Proportion of subjects whose eGFR was preserved  $\geq 30$  ml min<sup>-1</sup> 1.73 m<sup>-2</sup> was 82% at 5-year, predominantly in subjects whose ACR regressed to  $< 300$  mg/gCr. Cumulative incidences of ESRD and ESRD plus doubling of serum creatinine at 5-year were 8% (95%CI 3–13%) and 25% (95%CI 18–32%), respectively.

**Conclusion:** It is suggested that substantial improvements in blood pressure and blood glucose control may lead to a regression of macroalbuminuria and preservation of renal function, in about 50% of those who had already been suffering from overt diabetic nephropathy.

	SBP at one-year (mmHg)	
A1C at one-year (%)	>Median (129)	$\leq$ Median SBP (129)
>Median (7.2)	77 (95%CI 44–124)	142 (95%CI 88–213)
$\leq$ Median (7.2)	182 (95%CI 118–262)	254 (95%CI 180–341)

Incidence density (per 1000 person-years) of regression from macroalbuminuria (ACR  $\geq 300$  mg/gCr) to ACR  $< 300$  mg/gCr according to one-year SBP and A1C levels in subjects with T2DM who once had macroalbuminuria on their first visits.

## 1102

### Progression of diabetic nephropathy during long term RAS blockade

G. Andrésdóttir, M. Linnemann Jensen, P. Rossing;  
Steno Diabetes Center A/S, Gentofte, Denmark.

**Background and aims:** Previous studies have shown that antihypertensive treatment has a beneficial effect on progression of diabetic nephropathy. Blocking the Renin-Angiotensin System (RAS) is thought to benefit kidney function independent of the regulation of blood pressure and has been recommended for treatment of diabetic nephropathy since 2001. However, long term effects of RAS blockade have been questioned based on register studies. Our aim was to evaluate long term decline in renal function in diabetic ne-

phropathy during the last decade, in comparison to historic data before 2000 in type 1 and type 2 diabetic patients.

**Materials and methods:** This was an observational cohort study. All patients with diabetic nephropathy at our outpatient diabetes clinic were followed with annual measurements of GFR ( $^{51}\text{Cr}$ -EDTA plasma clearance). The study included all patients with a minimum of 3 measurements during the years 2000–2010 and at least 3 years of follow up. Since 2001, RAS blocking agents have been recommended to all our patients with diabetic nephropathy. Over 95% of our cohort was prescribed RAS blocking agents for more than half of the study period. With the same method we have previously published data on decline in GFR from 1983 to 2000 for type 1 diabetes (where 59% of patients were on ACE inhibitors during more than half of the study period) and from 1983–2003 for type 2 (where 24% were prescribed RAS blocking treatment at baseline).

**Results:** 315 type 1 diabetic patients met inclusion criteria. The mean (SD) GFR at baseline was 78 (29) ml/min/1.73m<sup>2</sup>, HbA<sub>1c</sub> 9.2 (1.4) %, blood pressure 140 (17) / 79 (8) mmHg, serum cholesterol 5.3 (1.0) mmol/l and albumin excretion rate (AER) median [interquartile range] was 420 [156–945] mg/24h. Patients were followed for 8.6 [5.6–9.9] years, with 7 [5–9] measurements of GFR. The rate of decline of GFR was 3.3 (3.1) ml/min/1.73m<sup>2</sup>/year, a 19% reduction (95%CI 5–34%,  $p=0.009$ ), compared to historically 4.0 (3.4) ml/min/1.73m<sup>2</sup>/year,  $n=301$ . 286 type 2 diabetic patients were included. The mean GFR at baseline was 80 (29) ml/min/1.73m<sup>2</sup>, HbA<sub>1c</sub> 8.5 (1.6), blood pressure 149 (17) / 82 (9) mmHg, serum cholesterol 4.8 (1.3) mmol/l and AER 436 [252–890] mg/24h. Patients were followed for a median of 6.0 [4.3–8.4] years with 5 [4–7] measurements of GFR. The annual mean decline in GFR was 4.4 (4.0) ml/min/1.73m<sup>2</sup>/year, reduced with 14% (95% CI 4–28%,  $p=0.04$ ) compared to historically 5.2 (4.1) ml/min/1.73m<sup>2</sup>/year,  $n=227$ . Baseline data in the historic and present cohorts were similar although AER was slightly lower in the present cohort, and blood pressure was lower for type 2 patients. In addition diabetes duration was longer for the present type 1 cohort.

**Conclusion:** Modern treatment of diabetic nephropathy, including long term blocking of the RAS, preserves renal function better than treatment used in the past decades where RAS inhibition was not standard.

## 1103

### Usefulness of UAER and GFR combination to predict all- cause mortality in type 2 diabetic patients

A.B. Mañas - Martínez, Y. Blasco- Lamarca, B. Campos- Gutiérrez, B. García- García, J. Altemir- Trallero, J.A. Gimeno- Orna, J. Ocón- Bretón; Endocrinology, Lozano Blesa Hospital, Zaragoza, Spain.

**Background and aims:** Stages of chronic kidney disease (CKD) are currently defined mainly by estimated glomerular filtration rate (eGFR). However mortality risk depends not only on eGFR but also on urinary albumin excretion rate (UAER). Our study was aimed to evaluate a new CKD staging system based on eGFR and UAER to predict all-cause mortality in type 2 diabetic patients.

**Materials and methods:** We designed a prospective cohort study with inclusion of 453 type 2 diabetic individuals with follow-up until death or March 2011. GFR (ml/min per 1.73 m<sup>2</sup>) was estimated by using the Modification of Diet in Renal Disease Study equation, and UAER (mg) by using 24-hour urine collection. CKD staging was accomplished in accordance with a system based on the NKF guidelines (current system) and in accordance with an alternative system of CKD risk categories. The alternative system was composed of five categories: group 0: eGFR  $\geq 60$  and UAER  $< 30$ ; group 1: eGFR  $\geq 60$  and UAER 30–300 or eGFR 45–59 and UAER  $< 30$ ; group 2: eGFR 30–44 and UAER  $< 30$  or eGFR 45–59 and UAER 30–300; group 3: eGFR 30–44 and UAER 30–300 or eGFR  $\geq 60$  and UAER  $> 300$  or eGFR  $< 30$  and UAER  $< 30$ ; group 4: eGFR  $< 30$  and UAER  $> 30$  or eGFR  $< 60$  and UAER  $> 300$ . Groups 3 and 4 were grouped. Incidence rates for all-cause mortality were calculated per 1000 persons-years. Comparison of the rates was done by Kaplan-Meier analysis and the log-rank test. Age and sex adjusted Cox's regression models were used to assess the predictive power of the two evaluated systems. The difference in the  $-2 \ln(L)$  between models follows a  $\chi^2$  distribution, with a higher  $\chi^2_{LR}$  value indicating a more powerful predictor.

**Results:** We included 453 type 2 diabetic patients (39.3% males). At baseline age of the study group was 65 (SD 9.3) years and duration of diabetes was 10.5 (SD 7.5) years. UAER was  $< 30$  in 321 subjects (70.8%), 30–300 in 105 (23.2%) and  $> 300$  in 27 (6%). eGFR was  $\geq 60$  in 318 (70.2%) and  $< 60$  in 135 (29.8%). According to the current system 234 (51.7%) patients belonged to stage 0, 84 (18.5%) to stages 1–2 and 135 (29.8%) to stages  $\geq 3$ . According to the alterna-

tive system 234 (51.6%) patients were classified in group 0, 152 (33.6%) in group 1, 33 (7.3%) in group 2 and 34 (7.5%) in groups 3–4. During 11.5 years follow-up, 207 (45.7%) patients died. Incidence rates of all-cause mortality were steadily increased in the successive current system stages: 28.7/1000 in stage 0, 46.3/1000 in stages 1–2 and 57.9/1000 in stages  $\geq 3$  ( $p < 0.0001$ ). Incidence rates were also steadily increased in the successive alternative system groups: 28.7/1000 in group 0, 42.7/1000 in group 1, 74.1/1000 in group 2 and 96.8/1000 in groups 3–4 ( $p < 0.0001$ ). The overall  $\chi^2$  of the age and sex adjusted model with the inclusion of eGFR and UAER was 133.1. The overall  $\chi^2$  of the age and sex adjusted model with inclusion of current-system risk categories was 111.4. The  $\chi^2$  increased up to 127.4 when the current system was replaced by the alternative one ( $p < 0.0001$  the difference between models). In a multivariate analysis including age, sex, hypertension, smoke, lipid profile, diabetes duration, A1c and prevalent macrovascular disease the alternative system was an independent predictor of mortality risk: group 1: HR 1.08 (CI 95%: 0.77–1.52;  $p=ns$ ); group 2: HR 1.71 (CI 95%: 1.03–2.83;  $p=0.038$ ); groups 3–4: HR 2.42 (CI 95%: 1.46–4.02;  $p=0.001$ ).

**Conclusion:** An alternative system of CKD classification which takes into account both, eGFR and EAUR, is superior to the current system mainly based on eGFR.

## 1104

### Prevalence of microvascular complications in European patients with type 2 diabetes mellitus with and without renal impairment: results of a large worldwide cohort study

I. Conget<sup>1</sup>, EDGE Steering Committee, J.-B. Gruenberger<sup>2</sup>, G. Bader<sup>2</sup>; <sup>1</sup>Diabetes Unit, Endocrinology Dept., Hospital Clinic i Universitari, Barcelona, Spain, <sup>2</sup>Novartis Pharma AG, Basel, Switzerland.

**Background and Aims:** Presence of renal impairment and microvascular complications are important considerations in determining prognosis and treatment in patients with type 2 diabetes mellitus (T2DM). We present results of a sub-analysis from the European cohort of the Effectiveness of Diabetes control with vildagliptin and vildagliptin/metformin (EDGE) study which compared the effectiveness and safety of vildagliptin with other oral antidiabetic drugs (OADs) in T2DM patients inadequately controlled by monotherapy, under real life conditions.

**Materials and methods:** EDGE was a prospective, multinational, non-interventional, observational study in adult T2DM patients. Patients only became eligible after the add-on treatment was chosen by the physician based on patient need. Data were collected on patient history, metabolic control and treatment. Overall, 45868 patients (intent to treat) were enrolled in 27 countries across the world. Of the 22045 patients enrolled in Europe, 12384 (58.2%) had serum creatinine measured at baseline. GFR was estimated (eGFR) according to the Modification of Diet in Renal Disease (MDRD) formula and the cohort was divided in to two groups (with renal impairment [eGFR  $< 60$  ml/min/1.73m<sup>2</sup>] or without renal impairment [eGFR  $\geq 60$  ml/min/1.73m<sup>2</sup>]).

**Results:** At baseline, 2216 (17.9%) patients had renal impairment. Patients with renal impairment were older and had a longer duration of diabetes than those without renal impairment, while HbA1c was similar in both groups. Overall, microvascular complications (collected from patients' history) were more frequent (17.7% vs 9.7%) in the group with renal impairment as compared to those without. The renal impairment group also had a higher proportion of patients with one (13.5% vs 8.1%) complication (nephropathy or neuropathy or retinopathy), two (3.5% vs 1.4%) complications and three (0.7% vs 0.2%) complications. Overall, 124 patients had severe renal impairment (eGFR  $< 30$  ml/min/1.73m<sup>2</sup>). Metformin was the most commonly used OAD in both groups, with and without renal impairment. Of the 10812 (87.3%) patients taking metformin, 1823 (16.8%) had eGFR  $< 60$  ml/min/1.73m<sup>2</sup>.

**Conclusion:** Data from this large observational European cohort of patients with T2DM inadequately controlled by OAD monotherapy showed a far from negligible proportion with renal impairment. Patients with T2DM and renal impairment had a higher prevalence of microvascular complications and inadequate metabolic control, especially given the need for better glycaemic control in this patient population. Nearly 17% of patients using metformin monotherapy have some degree of renal impairment for which metformin is contraindicated, confirming results from earlier studies.

	eGFR <60 ml/ min/1.73m <sup>2</sup> (N=2216)	eGFR ≥60 ml/ min/1.73m <sup>2</sup> (N=10168)

### Defining the relationship between HbA<sub>1c</sub> and average plasma glucose in type 2 diabetes and chronic kidney disease

C. Lo<sup>1,2</sup>, M. Lui<sup>1</sup>, S. Ranasinha<sup>1</sup>, H.J. Teede<sup>1,2</sup>, P.G. Kerr<sup>3</sup>, K. Polkinghorne<sup>3</sup>, D.M. Nathan<sup>4,5</sup>, H. Zheng<sup>6,5</sup>, S. Zoungas<sup>1,7</sup>,  
<sup>1</sup>Diabetes and Cardiovascular Research Unit, Monash University, Clayton, Australia, <sup>2</sup>Diabetes and Vascular Unit, Monash Medical Centre, Clayton, Australia, <sup>3</sup>Renal Unit, Monash Medical Centre, Clayton, Australia, <sup>4</sup>Diabetes Centre, Massachusetts General Hospital, Massachusetts, USA, <sup>5</sup>Harvard Medical School, Boston, USA, <sup>6</sup>Biostatistics Centre, Massachusetts General Hospital, Boston, USA, <sup>7</sup>Diabetes Research Program, The George Institute of Public Health, Sydney, Australia.

**Background and aims:** Diabetic chronic kidney disease is a growing problem globally. Glycemic control is important for the prevention of adverse kidney outcomes. However, the utility of assessing HbA<sub>1c</sub> levels in patients with chronic kidney disease (CKD) remains unclear. Here we examine the relationship between average plasma glucose (AG) and HbA<sub>1c</sub> in patients with and without CKD (stages 3 to 5).

**Materials and methods:** 43 patients with type 2 diabetes (T2DM) and CKD (33% stage 3, 23% stage 4 and 44% stage 5) with stable glycemic control, no recent changes in glucose lowering or erythropoietin therapy and no recent blood transfusions were prospectively studied and age-matched to 104 patients without CKD randomly selected from the A1c-Derived Average Glucose study. Over a 3-month period, average plasma glucose (AG) was calculated from 7–8 point self-glucose monitoring (SGM) performed 3–5 days/week and continuous glucose monitoring (CGM) performed for 2–3 days/month. Mean HbA<sub>1c</sub> was calculated as the average of levels measured at baseline and then monthly over 3 months. The relationship between AG (calculated separately from SGM and CGM) and HbA<sub>1c</sub> was analysed using multi-variable regression models.

**Results:** The CKD and non-CKD groups were well matched for age (61 ± 4 vs. 63 ± 9.6 years) and gender (40% vs. 37% were female). Mean AG and HbA<sub>1c</sub> levels were similar (CKD vs. non-CKD, AG: 9.1 ± 2.5 vs. 8.4 ± 1.9 mmol/L and HbA<sub>1c</sub>: 7.1 ± 1.4 vs. 7.0 ± 1.0 %, both p > 0.05). A linear relationship between AG and HbA<sub>1c</sub> was observed irrespective of the presence and stage of CKD. The relationship was weaker in patients with stage 4–5 CKD (non-CKD R<sup>2</sup> 0.75, stage 3 CKD R<sup>2</sup> 0.79 and stage 4–5 CKD R<sup>2</sup> 0.34). The inclusion of erythropoietin use (EPO) into the model rendered the effect of CKD stage insignificant, suggesting that the treatment of anaemia with EPO results in a systematic underestimation of the AG derived from the HbA<sub>1c</sub>: AG (mmol/L) = 1.4(HbA<sub>1c</sub> %) + 1.1 × [EPO yes (1) or no (0)] - 1.6 (p < 0.0001). However the slope of the relationship between AG and HbA<sub>1c</sub> was not modified by EPO status. In a separate analysis of CKD patients, pre-prandial AG levels were more strongly related to HbA<sub>1c</sub> than postprandial AG levels (R<sup>2</sup><sub>pre</sub> 0.59 vs. R<sup>2</sup><sub>post</sub> 0.30, p for difference in slopes < 0.001). A sensitivity analysis replacing SGM with CGM measurements produced consistent results.

**Conclusion:** In patients with type 2 diabetes and CKD, there is a linear relationship between HbA<sub>1c</sub> and AG that was more attributable to pre-prandial rather than postprandial AG levels. Compared to non-CKD patients, substantial attenuation of this relationship is observed with stage 4–5 CKD and EPO use but not stage 3 CKD. Using the derived equation in advanced CKD will

provide both clinicians and patients with more accurate information on day to day AG levels.

### Similar correlations between HbA<sub>1c</sub> and fasting blood glucose level independently of renal function in elder type 2 diabetic patients in the Gerodiab cohort

J. Doucet<sup>1</sup>, B. Bauduceau<sup>2</sup>, C. Verny<sup>3</sup>, J.-P. Le Floch<sup>4</sup>, SFD-SFGG Intergroup, The Gerodiab Group;

<sup>1</sup>Rouen University Hospital, Boisguillaume, <sup>2</sup>Begin University Hospital, Saint-Mande, <sup>3</sup>Bicêtre University Hospital, Paris, <sup>4</sup>Clinique de Villecresnes, Villecresnes, France.

**Background and aims:** Gerodiab is a French observational study designed to analyse the factors associated with mortality and morbidity in type 2 diabetic patients 70 year-old and over, and especially HbA<sub>1c</sub> levels. HbA<sub>1c</sub> is considered the gold standard marker of glycemic control in diabetic patients and used to treatment adaptation. However, in patients with renal insufficiency, many factors could alter the reliability of HbA<sub>1c</sub> levels, including anemia, a decreased production of erythropoietin and changes related to dialyses. In elder patients, renal dysfunction is common and thus the interest of HbA<sub>1c</sub> can be questioned. The aim of this study was to test the interest of HbA<sub>1c</sub> as a marker of glucose control in the patients included in the Gerodiab cohort.

**Materials and methods:** The correlations between HbA<sub>1c</sub> and fasting blood glucose (FBG) were analysed both in the population as a whole, and at 3 different levels of MDRD, using Pearson's linear regression.

**Results:** At inclusion, 779 out of 987 patients (375 men and 404 women, age [mean ± SD]: 77 ± 5 yr, duration of diabetes: 18 ± 12 yr) had simultaneous MDRD computation (67.4 ± 22.7 ml/min), fasting blood glucose (7.94 ± 2.89 mmol/l) and HbA<sub>1c</sub> (7.6 ± 1.3 %) assays. Similar correlations were found in the global population: HbA<sub>1c</sub> = 5.95 + 1.13 FBG; R<sup>2</sup> = 0.194; P < 0.001, in patients with MDRD < 30 ml/min (n = 27): HbA<sub>1c</sub> = 5.76 + 1.12 FBG; R<sup>2</sup> = 0.246; P < 0.001, in patients with MDRD [30–60 ml/min (n = 271): HbA<sub>1c</sub> = 6.52 + 0.80 FBG; R<sup>2</sup> = 0.096; P < 0.001, and in those with MDRD ≥ 60 ml/min (n = 481): HbA<sub>1c</sub> = 5.73 + 1.27 FBG; R<sup>2</sup> = 0.250; P < 0.001).

**Conclusion:** These results suggest that HbA<sub>1c</sub> can be used as a reliable marker of blood glucose control in elder type 2 diabetic patients, including patients with renal dysfunction.

### Transplantation of bone marrow-derived mononuclear cells improves sensory disorders in the early stage of streptozotocin-induced diabetes in rats

K. Naruse<sup>1</sup>, J. Sato<sup>2</sup>, M. Funakubo<sup>2</sup>, M. Hata<sup>3</sup>, N. Nakamura<sup>1</sup>, Y. Kobayashi<sup>1</sup>, H. Kamiya<sup>4</sup>, T. Matsubara<sup>1</sup>, J. Nakamura<sup>4</sup>;

<sup>1</sup>Department of Internal Medicine, School of Dentistry, Aichi-Gakuin University, Nagoya, <sup>2</sup>Puturistic Environmental Simulation Center, Research Institute of Environmental Medicine, Nagoya University, <sup>3</sup>Department of Removable Prosthodontics, School of Dentistry, Aichi-Gakuin University, Nagoya, <sup>4</sup>Division of Diabetes, Department of Internal Medicine, Aichi Medical University, Nagakute, Japan.

**Background and aims:** Diabetic neuropathy is the most common complication of diabetes and patients with diabetic neuropathy suffer from the abnormal peripheral sensations, such as paresthesia, allodynia, hyperalgesia, and spontaneous pain. We have previously shown that the transplantation of cultured endothelial progenitor cells or mesenchymal stem cells ameliorated diabetic neuropathy in rats. In this study, we investigated whether transplantation of freshly isolated bone marrow-derived mononuclear cells (BM-MNCs) alleviates neuropathic pain in the early stage of streptozotocin (STZ)-induced diabetic rats.

**Materials and methods:** Two weeks after STZ injection into Sprague-Dawley (SD) rats, BM-MNCs or vehicle saline were injected into the unilateral hind limb muscles. Mechanical hyperalgesia and cold allodynia in SD rats were measured as the number of foot withdrawals to von Frey hair stimulation and acetone application, respectively. Two weeks after the BM-MNC transplantation, sciatic motor nerve conduction velocity (MNCV), sensory nerve conduction velocity (SNCV), sciatic nerve blood flow (SNBF), mRNA / protein expressions and histology were assessed.

**Results:** Diabetic rats showed mechanical hyperalgesia and cold allodynia. The transplantation of BM-MNCs significantly improved these sensational abnormalities in the BM-MNC-injected side of diabetic rats. The slowed MNCV/SNCV and decreased SNBF in diabetic rats were improved in the BM-MNC-injected side (MNCV: the saline-injected side;  $36.4 \pm 2.6$  m/s, the BM-MNC-injected side;  $51.4 \pm 0.8$  m/s, SNCV: the saline-injected side;  $31.7 \pm 2.9$  m/s, the BM-MNC-injected side;  $47.5 \pm 3.6$  m/s,  $P < 0.001$  for both). BM-MNC transplantation improved the decreased mRNA expression of NT-3 and number of microvessels in the hind limb muscles. The expression of calcitonin gene-related peptide was increased in the plantar skin of diabetic rats, which was abolished by BM-MNC transplantation. There was no distinct effect of BM-MNC transplantation on the intraepidermal nerve fiber density. **Conclusion:** These results suggest that autologous transplantation of BM-MNCs could be a novel strategy for the treatment of painful diabetic neuropathy.

### Effect of human dental pulp stem cell transplantation on diabetic polyneuropathy

M. Hata<sup>1</sup>, K. Naruse<sup>2</sup>, Y. Kobayashi<sup>2</sup>, N. Nakamura<sup>2</sup>, S. Ozawa<sup>1</sup>, M. Shimizu<sup>3</sup>, K. Miyazawa<sup>4</sup>, M. Omi<sup>1</sup>, H. Kamiya<sup>5</sup>, J. Nakamura<sup>5</sup>, S. Goto<sup>4</sup>, K. Kurita<sup>3</sup>, Y. Tanaka<sup>1</sup>, T. Matsubara<sup>2</sup>;

<sup>1</sup>Removable Prosthodontics, School of Dentistry Aichi-Gakuin University, <sup>2</sup>Internal Medicine, School of Dentistry Aichi-Gakuin University, <sup>3</sup>Oral and Maxillofacial Surgery, School of Dentistry Aichi-Gakuin University, <sup>4</sup>Orthodontics, School of Dentistry Aichi-Gakuin University, <sup>5</sup>Internal Medicine, Aichi Medical University School of Medicine, Nagoya, Japan.

**Background and aims:** Diabetic neuropathy is the most common complication of diabetes. We have previously reported that the transplantation of cultured endothelial progenitor cells or bone marrow-derived mesenchymal stem cells ameliorated diabetic neuropathy in rats. The critical issue of cell transplantation is how to collect cells and maintain cell functions. Human dental pulp stem cells (hDPSCs) which are a sort of mesenchymal stem cells located in the dental pulp cavity are expected as a source of regenerative medicine, since hDPSCs can be isolated from wisdom tooth extraction or premolar extraction for orthodontic reasons. The aim of this study is to evaluate the

therapeutic potential of hDPSCs transplantation on diabetic polyneuropathy in streptozotocin (STZ)-induced diabetic nude mice.

**Materials and methods:** We collected human impacted third molars from 4 adults (13–23 years of age) at our hospital. Written informed consent was obtained from each donor. Dental pulp was extracted by cutting teeth and hDPSCs were isolated by collagen digestion method and cultured as previously described. Identification of hDPSCs was analyzed by surface makers using a fluorescence activated cell sorter and differentiation capabilities into adipocytes and osteoblasts. Diabetes was induced by an intraperitoneal injection of STZ in 6 week-old BALB/cA/Jcl-nu/nu mice. Eight weeks after STZ injection, hDPSCs ( $1 \times 10^5$  cells/limb) were transplanted into unilateral hindlimb skeletal muscles of normal and diabetic mice. Saline was injected into the other side as control. Sciatic blood flow (SNBF), sciatic motor /sensory nerve conduction velocity (MNCV/SNCV) and current perception threshold (CPT) were evaluated 4 and 16 weeks after the transplantation of hDPSCs. Immunohistological analysis of hindlimb skeletal muscles was also performed at the end of the experiments.

**Results:** Flow cytometric analyses showed the positive stainings of CD29 and CD90 and negative stainings of CD34 and CD45. hDPSCs differentiated into osteoblasts and adipocytes by each induction media. Diabetic mice showed significant reductions in SNBF, MNCV and SNCV and increase in CPTs in the control side compared with normal mice. Transplantation of hDPSCs significantly ameliorated the impaired SNBF, MNCV, SNCV and CPTs in the hDPSCs-injected side of diabetic mice. Immunohistological study revealed that the transplanted hDPSCs were located around the muscle bundles and not differentiated into adipocytes nor osteoblasts.

**Conclusion:** We have demonstrated the effects of hDPSC transplantation for diabetic neuropathy without any adverse effects, suggesting that the transplantation of hDPSCs could be a new strategy for the treatment of diabetic neuropathy.

### Atorvastatin improves baroreflex sensitivity in patients with type 2 diabetes and dyslipidaemia

P. Grigoropoulos<sup>1</sup>, I. Eleftheriadou<sup>1</sup>, C. Zoupas<sup>1</sup>, A. Tsiakou<sup>1</sup>, S. Kalopita<sup>1</sup>, A. Kokkinos<sup>1</sup>, D. Perrea<sup>2</sup>, N. Katsilambros<sup>1</sup>, N. Tentolouris<sup>1</sup>;

<sup>1</sup>1st Department of Propaeudetic Medicine, Athens University Medical School, Laiko Hospital, <sup>2</sup>Laboratory of Experimental Surgery and Surgical Research, Athens University Medical School, Greece.

**Background and aims:** Baroreflex sensitivity (BRS) is reduced in patients with type 2 diabetes mellitus (T2DM), even in the absence of clinically apparent autonomic neuropathy. Reduced BRS has been associated with fatal ventricular arrhythmias and impaired regulation of blood pressure. Statins improve endothelial function and have been shown to have a neuroprotective effect. Therapy with statins improved BRS in subjects with hypercholesterolaemia without diabetes. However, no data exist on the effect of statins on BRS in individuals with T2DM. Aim of this study was to examine the effect of one year administration of low dose of atorvastatin on BRS in subjects with T2DM.

**Materials and methods:** A total of 82 patients with T2DM and dyslipidemia were recruited. The main inclusion criteria were age between 40–75 years, low density lipoprotein cholesterol (LDLc)  $\geq 100$  mg/dl. The main exclusive criteria were the presence of clinically apparent macrovascular disease and use of medications with known effect on autonomous nervous system activity. Forty-six patients (16 men/30 women, mean age  $60.37 \pm 8.53$ ) were assigned to atorvastatin (10 mg per day) and low-fat diet, and 36 patients (15 men/20 women, mean age  $59.06 \pm 9.23$ ) to low-fat diet only. Both groups were comparable regarding age, diabetes duration, baseline serum lipids, HbA1c, arterial blood pressure and BRS values. BRS was measured by the sequence method using the BaroCor system (Atcor Medical, Australia). All patients underwent 3 more visits, at 3, 6 and 12 months, during which the same blood tests and BRS estimation were repeated.

**Results:** Atorvastatin significantly reduced total cholesterol by 27.22% (from  $235.48 \pm 28.27$  mg/dl to  $171.41 \pm 21.33$  mg/dl,  $p < 0.001$ ), LDLc by 37.07% (from  $154.93 \pm 26.40$  mg/dl to  $97.50 \pm 22.29$  mg/dl,  $p < 0.001$ ) and TG by 19.10% (from  $144.26 \pm 70.35$  mg/dl to  $116.70 \pm 54.38$  mg/dl,  $p = 0.001$ ) after 12 months; HDL cholesterol (HDLc) remained unaffected ( $p = 0.53$ ). In the diet-treated group, no significant improvement of lipids was achieved. BRS was significantly improved in atorvastatin treated patients after 12 months therapy from  $6.46 \pm 2.79$  msec/mmHg to  $8.05 \pm 4.28$  msec/mmHg ( $p = 0.036$ ). Diet had no influence on BRS values. No difference in BMI, arterial blood pressure, heart rate, HbA1c, and fasting glucose was observed at both groups compared with baseline.

**Conclusion:** Long-term treatment with even a low dose of atorvastatin, beyond the beneficial effects on plasma lipids, improves BRS in patients with T2DM and dyslipidaemia.

## 1110

### Pharmacokinetics, safety, and tolerability of a long-acting C-peptide (CBX129801) in patients with type 1 diabetes

H. Foyt, M. Daniels, M. Milad, J. Wahren;  
Cebix Inc, La Jolla, USA.

**Background and aims:** C-peptide is co-secreted in equimolar amounts with insulin in response to elevations in blood glucose. Accumulating data suggest that C-peptide is a bioactive peptide in its own right and that its absence in type 1 diabetes patients is an important contributing factor to the onset and progression of long-term complications. In vitro studies have shown that C-peptide stimulates  $\text{Na}^+/\text{K}^+$ -ATPase and endothelial nitric oxide synthase (eNOS) and increases the expression of transcription factors important for cellular growth and cytoprotective and anti-inflammatory processes. Administration of C-peptide in type 1 diabetes patients with early stage neuropathy or nephropathy has demonstrated beneficial effects on peripheral and autonomic nerve function as well as renal function. However, efforts to replace circulating levels of C-peptide in type 1 diabetes patients have been stymied by its short biological half-life (~1 h), thus requiring multiple injections per day to mimic physiological exposure. A long-acting C-peptide CBX129801 has been developed for subcutaneous (SC) delivery following PEGylation of the peptide's N-terminus, distal from the biologically active C-terminus.

**Materials and methods:** A randomized, blinded, placebo-controlled, serial-cohort, multiple ascending dose Phase 1 study with CBX129801 has been conducted. Thirty type 1 diabetes patients (10 subjects per cohort; 8 active/2 placebo) were dosed SC at one of three dose levels: 0.3 mg, 1.0 mg (estimated C-peptide "replacement" dose level), and 3.3 mg for up to four weekly doses. Assessments of the safety, tolerability, and the single and multiple dose pharmacokinetics (PK) of plasma CBX129801 were conducted.

**Results:** Peak concentrations ( $C_{\max}$ ) generally occurred 2–4 days after SC administration.  $C_{\max}$  and AUC increased in direct proportion to increasing dose. Single dose PK was predictive of multiple dose PK. Following multiple doses of 0.3, 1.0, and 3.3 mg per week, the corresponding geometric mean  $C_{\max}$  values were 0.69, 2.3, and 10.8 nM; AUC<sub>tau</sub> values were 4.2, 14.2, and 64.5 nM·day; and  $C_{\min}$  values were 0.46, 1.60 and 6.54 nM, respectively. The mean plasma  $t_{1/2}$  of CBX129801 was 6–7 days, representing a 150-fold increase in the  $t_{1/2}$  relative to native C-peptide. CBX129801 was safe and well tolerated with no SAEs reported. The PK data from these 3 cohorts were compiled and modeled, and plasma concentration-time profiles were simulated. Simulations showed that a maintenance dose of 0.8 mg administered weekly will yield the targeted 1 nM trough plasma concentration in ~95% of patients, which represents physiologic replacement of C-peptide. This maintenance dose (0.8 mg/week) was utilized in a follow-up Phase 2 study enrolling 40 patients with SC dosing throughout the first 12 weeks with study duration of 15 weeks. Pharmacodynamic data were collected from both studies at baseline, 6 weeks, and 12 weeks in the form of electrophysiological measurements, including sural sensory nerve conduction velocities (SNCV). An exploratory responder analysis from the Phase 1 study, defined as an improvement in SNCV of >0.75 m/sec above baseline for the sural nerve in both legs, showed a favorable response for the CBX129801-treated patients relative to placebo; Phase 2 SNCV data are pending.

**Conclusion:** It is concluded that CBX129801 is safe and well tolerated in type 1 diabetes patients, and the  $t_{1/2}$  supports weekly administration. CBX129801 is a potentially attractive therapeutic agent that warrants additional testing in larger clinical trials.

Clinical Trial Registration Number: NCT 01293461

## 1111

### HM-VN118 inhibits VEGF-induced retinal vascular leakage and hypoxia-induced neovascularisation through reduced matrix metalloproteinase activity

J. Kim, C.-S. Kim, Y.M. Lee, E. Sohn, K. Jo, S.S. Dam, J.S. Kim;  
Traditional Korean Medicine (TKM) Based Herbal Drug Research Group,  
Korea Institute of Oriental Medicine, Daejeon, Republic of Korea.

**Background and aims:** Diabetes alters the structure and function of retinal vasculature, including the alteration of the blood-retinal barrier (BRB) and

the formation of retinal neovascularization. The aim of this study was to investigate the potential preventive effect of HM-VN118, an ethanolic extract of *Homonoia riparia* Lour., on VEGF-induced retinal vascular leakage and hypoxia-induced neovascularization in vivo.

**Materials and methods:** HM-VN118 was injected intraperitoneally in a rat model of VEGF-induced retinal vascular permeability and a mouse model of oxygen-induced retinopathy (OIR). BRB permeability was quantified using fluorescein angiography. Retinal angiogenesis was assessed by whole mount immunofluorescence staining of retinas. Matrix metalloproteinases (MMP) activity and tight junction protein were examined in retinal protein lysates and whole mount retinas

**Results:** When normoglycemic rats were intravitreally injected with VEGF, there was widespread leakage of fluorescein from the retinal vasculature when compared to control retinas. Treatment with HM-VN118 was shown to reduce VEGF-induced permeability and the loss of tight junction protein. Retinal neovascularization in the OIR model was significantly inhibited by HM-VN118. In addition, increases of both activity and expression of MMP-2 and MMP-9 was attenuated by the treatment of HM-VN118 in both animal models.

**Conclusion:** These results suggest that MMPs are involved in the process of VEGF-induced vascular leakage and hypoxia-induced retinal neovascularization and HM-VN118 might have therapeutic potential for the treatment of diabetic retinopathy.

## 1112

### Topical administration of somatostatin prevents retinal neurodegeneration in experimental diabetes

C. Hernandez<sup>1</sup>, M. Garcia-Ramirez<sup>1</sup>, L. Corraliza<sup>1</sup>, A. Ciudin<sup>1</sup>, B. Ponsati<sup>2</sup>, J. Fernández-Carneado<sup>2</sup>, J. Farrera-Sinfreu<sup>2</sup>, R. Simó<sup>1</sup>;  
<sup>1</sup>CIBERDEM and Diabetes and Metabolism Research Unit, Vall d'Hebron Research Institute, <sup>2</sup>BCN Peptides, S.A., Barcelona, Spain.

**Introduction/aim:** There is growing evidence to suggest that retinal neurodegeneration is an early event in the pathogenesis of diabetic retinopathy (DR). Consequently, neuroprotective drugs could open up a new strategy for the treatment of the early stages of DR. Somatostatin (SST) has a neuroprotective action and its production is downregulated in the diabetic eye. The aim of the study was to test the hypothesis that topical administration of SST is useful in preventing retinal neurodegeneration. In addition, the effects of SST eye drops on apoptotic/survival signalling pathways and retinal glutamate levels were examined. Finally, the possibility that SST acts through upregulation of glutamate/aspartate transporter (GLAST), a major glutamate transporter in the retina which is essential for preventing glutamate accumulation was also explored.

**Material and methods:** Male Sprague Dawley rats in which diabetes was induced by streptozotocin were treated with either eye-drops of SST (n=8) or vehicle (n=8) for 15 days. Non-diabetic Sprague Dawley rats (n=8) treated with vehicle served as the control group. Electroretinography (ERG) studies were performed before starting treatment and one day prior to death. Glial activation was evaluated by measuring glial fibrillar acidic protein (GFAP) by immunofluorescence. Apoptosis was assessed by TUNEL assay. Proapoptotic molecules (FasL, caspase-8, total Bid, truncated Bid, and active caspase -3) and anti-apoptotic markers (BclxL) were measured by Western-blot. Glutamate was measured by LC-MS/MS. The expression of GLAST was assessed by RT-PCR and immunohistochemistry.

**Results:** Treatment with SST eye drops prevented both ERG abnormalities (reduction in b-wave amplitude and increase in b-wave implicit time), and the characteristic features of neurodegeneration (glial activation and apoptosis) caused by diabetes. Topical administration of SST abrogated the increase of proapoptotic signalling induced by diabetes (FasL, Bid, and activation of caspase-8 and caspase-3), and prevented the downregulation of BclxL. In addition, SST eye drops significantly reduced glutamate retinal levels and prevented the downregulation of GLAST (mRNA and protein levels) induced by diabetes.

**Conclusion:** Topical administration of SST has a potent effect in preventing the retinal neurodegenerative process that occurs in the early stages of DR. A preventive effect on the impairment of survival/apoptotic signalling induced by diabetes and a significant reduction in glutamate-induced excitotoxicity are among the mechanisms by which SST exerts its beneficial actions.

### Effects of ginkgo biloba extract on prevention of development of diabetic nephropathy in type 2 diabetic patients

Y. Wang<sup>1</sup>, Z. Sun<sup>1</sup>, J. Yu<sup>2</sup>, B. Yang<sup>1</sup>, H. Yin<sup>1</sup>, Y. Wang<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Southeast University, <sup>2</sup>Department of Endocrinology, Jiangsu Province Hospital of TCM, Nanjing, China.

**Background and aims:** Diabetic nephropathy (DN) has become the leading cause of end stage renal failure, and prevention or retardation of DN has become a major goal in biomedical research. Ginkgo biloba extract (GBE) is one of the most widely used herbal medicines in the world. Our research is to observe the preventive effects of GBE on early stage of DN in type 2 diabetic patients.

**Materials and methods:** A randomized, double-blind, placebo-controlled clinical trial of 210 type 2 diabetic patients (ACR, urine albumin-to-creatinine ratio < 30mg/mmol) aged 50 to 70 years, conducted in 2 hospitals in China between 2008 and 2011. Participants received 24 mg of EGB thrice daily or placebo for 3 years. And 199 participants finished the 3-year study (GBE group, n=87; placebo group, n=112). Fasting blood glucose (FBG), postprandial blood glucose (PBG), HbA1c, total cholesterol (TC), LDL cholesterol (LDL-C), HDL cholesterol (HDL-C), triglyceride (TG), blood creatinine (Cr), blood urea nitrogen (BUN), urine mAlb, urine Cr, ACR (urine albumin-to-creatinine ratio) were measured by different methods. Odds ratios (ORs), 95% confidence intervals were calculated using generalized estimating equations (GEE) for repeated measures, adjusting for course of disease, age, gender.

**Results:** There were no differences in FBG, PBG, TC, LDL-C, HDL-C, TG, HbA1c between GBE and placebo ( $p < 0.05$ ). To assess the effect of GBE on ACR, GEE models showed statistical significance in clinical effect between the GBE group and the placebo group ( $p = 0.02$ ). Compared with placebo, the preventive effects of GBE is better (ORs=2.17).

**Conclusion:** The use of GBE, 24 mg thrice daily, results in less ACR increase in type 2 diabetic patients in three years. GBE has the preventive effects on early stage of type 2 DN. Combined treatment of traditional Chinese medicine and western medicine may be a good treatment to the prevention or retardation of DN. Table 1. The percentage of patients that ACR < 30mg/mmol in different center in three years after GBE and placebo treatment.

Group	Center	No.	Time		
			1 year	2 year	3 year
GBE group	1	58	94.83%	87.93%	82.76%
	2	45	91.11%	97.78%	95.56%
	Total	103	92.97%	92.85%	89.16%
placebo group	1	50	82%	78%	80%
	2	46	91.3%	91.3%	89.13%
	Total	96	86.65%	84.65%	84.56%

## 1114

### Protection effect and mechanism of Compound Xue Shuantong Capsule on diabetic nephropathy

J. Yan, X. Xia, F. Xu, L. Zhang, Y. Zhao, H. Liang, J. Weng;

The third affiliated hospital of Sun Yat-Sen University, Guangzhou, China.

**Background and aims:** The overexpression of reactive oxygen species (ROS) in the presence of high glucose induces dysfunction in glomerulus mesangial cell and podocytes. Up-regulation of matrix metalloproteinase (MMP)-2 lead to metabolic disorders in the extracellular matrix (ECM). The above disorders may contribute pathologically to the development of diabetic nephropathy. Chinese Compound Xue shuantong Capsule (XST) contains four Chinese herbs: Sanqi (panax notoginseng), huangqi, danshen and scrophulariaceae. The present study was aimed to investigate protective effect and mechanism of XST on diabetic rat model with nephropathy.

**Materials and methods:** A total twenty-eight male Sprague Dawley (SD) rats were induced to hyperglycemia (three days later, fasting blood glucose > 16.7mmol/L) by peritoneal injection with streptozotocin (STZ, 50mg/kg) and divided into four groups: diabetic nephropathy group (DN, treated with vehicle), Irbesartan group (IB, 20mg/kg/d), low-dosage XST group (LX, 900mg/kg/d) and high-dosage XST group (HX, 1800mg/kg/d). Normal SD rats (n=7) were used as control group (NC). After 12-week intervention, urine protein was checked. Kidney pathological morphology was observed by HE, Masson, PAS stain and electron microscope. Blood nitric oxide (NO), superoxide dis-

mutase (SOD) and malondialdehyde (MDA) were detected. The expression of MMP-2 was detected using real time-PCR and western blotting. Analysis of variance (ANOVA) and Least-significant difference (LSD) were used for data analysis.

**Results:** Urinary albumin was decreased in three intervention group than those in DN group. Irbesartan and XST treatment had no effect on both blood glucose and bodyweight. Irbesartan and XST ameliorated pathological injury on glomerular basement membrane, podocytes, mesangial cells by HE, Masson, PAS stain and electron microscope. There were no significant difference between low-dosage XST and high-dosage XST group. The expression of MMP-2 was increased in DN group than those in NC group. Three intervention group had no effect on MMP-2 expression. The content of NO was significantly lower in IB (15.78±1.21 μmol/L), LX (41.94±9.63 μmol/L) and HX group (14.71±1.92 μmol/L) than those in DN group (104.86±11.02 μmol/L, both  $P < 0.05$ ). The content of MDA was also decreased in IB (5.12±1.64 mmol/ml), LX (6.63±0.87 mmol/ml), and HX group (4.54±1.23 mmol/ml) than those in DN group (19.60±1.56 mmol/ml, both  $P < 0.05$ ). Compared with DN group (222.22±19.78 U/ml), the activity of SOD was increased in IB (242.59±16.67 U/ml), LX (230.89±17.76 U/ml) and HX group (236.97±23.90 U/ml) (both  $P < 0.05$ ).

**Conclusion:** Compound Xue shuantong Capsule reduced urine protein and ameliorated pathological injury in kidney. The protective effect of Compound Xue shuantong Capsule may be related with suppression of oxidative stress and not with ECM metabolism.

## 1115

### Dipeptidyl peptidase-4 inhibitor, vildagliptin analogue, exerts renoprotective effects independent of blood glucose lowering actions in type 1 diabetic rats

R. Koderä<sup>1</sup>, K. Shikata<sup>1,2</sup>, T. Takatsuka<sup>2</sup>, S. Miyamoto<sup>2</sup>, N. Kajitani<sup>2</sup>, D. Hirota<sup>2</sup>, D. Ogawa<sup>3</sup>, H. Makino<sup>2</sup>;

<sup>1</sup>Center for Innovative Clinical Medicine Okayama University Hospital,

<sup>2</sup>Medicine and Clinical Science, Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, <sup>3</sup>Diabetic Nephropathy, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan.

**Background and aims:** We have recently shown the renoprotective effects of Glucagon like peptide-1 (GLP-1) receptor agonist, exendin-4, through anti-inflammatory effects independent of blood glucose lowering actions in type 1 diabetic rats. GLP-1 receptor is expressed on glomerular endothelial cells and monocytes/macrophages. Exendin-4 directly exerts protective effects against diabetic nephropathy by inhibition of the interaction between macrophages and glomerular endothelial cells which promotes inflammatory process. However, the renoprotective effect of dipeptidyl peptidase-4 (DPP-4) inhibitor has remained unclear. The aim of this study is to clarify the effects of DPP-4 inhibitor on diabetic nephropathy.

**Materials and methods:** Five-week old male Sprague-Dawley rats were divided into three groups; non-diabetic: ND, diabetic rats without treatment: DM, diabetic rats treated with vildagliptin analog (PKF-275): DM+PKF. Rats were administered orally with PKF-275 (10μg/kg/day, DM+PKF) or vehicle (ND and DM) every day for 8 weeks. To investigate the effects of PKF, we measured urinary albumin excretion and creatinine clearance and evaluated the renal histological morphometry. We also examined the expression of pro-inflammatory molecules in kidney tissues by quantitative real-time RT-PCR and immunostaining.

**Results:** PKF treatment significantly reduced urinary albumin excretion (Mean values; DM 699μg/day, DM+PKF 420μg/day, DM vs DM+PKF:  $P < 0.05$ ) without change of blood glucose levels and blood pressure. PKF didn't affect hyperfiltration in diabetic rats. In the renal histological morphometry, PKF significantly attenuated mesangial matrix expansion (mesangial matrix index; DM: 9.4%, DM+PKF: 8%, DM vs DM+PKF:  $P < 0.05$ ), but not glomerular size. Treatment with PKF also significantly reduced expression of intercellular adhesion molecule-1 (DM vs DM+PKF:  $P < 0.05$ ) in the cortex and glomeruli, and prevented macrophage infiltration into kidney tissues.

**Conclusion:** Treatment with PKF ameliorated albuminuria, renal tissue injuries and the expression of proinflammatory molecules in the kidney, independent of blood glucose levels and blood pressure in type 1 diabetic rats. These results suggest that PKF ameliorated diabetic renal injuries through anti-inflammatory effects. DPP-4 inhibitor as well as GLP-1 receptor agonist

might be effective for diabetic nephropathy independent of blood glucose lowering effect.

## 1116

### Low protein diet inhibits uric acid synthesis and attenuates renal damage in streptozotocin- induced diabetic rats

J. Ran<sup>1</sup>, J. Ma<sup>1</sup>, Y. Liu<sup>2</sup>, R. Tan<sup>3</sup>, H. Liu<sup>1</sup>, G. Lao<sup>1</sup>;

<sup>1</sup>Endocrinology Department, <sup>2</sup>Nephrology Department, <sup>3</sup>Institute of clinical nutrition, Guangzhou Red Cross Hospital, China.

**Background and aims:** Several studies indicated that hyperuricemia may link to the worsening of diabetic nephropathy (DN). Meanwhile, low protein diet (LPD) retards exacerbations of renal damage in chronic kidney disease. Whether LPD exert the same effect on DN through lowering blood uric acid still remains unclear. In this study, we then explore effects of LPD on uric acid metabolism and progression of renal damage in streptozotocin (STZ)-induced diabetic rats.

**Materials and methods:** Thirty STZ-induced rats were fed with LPD (8%, n=15) and normal protein diet (NPD, 18%, n=15) for 12 weeks respectively, twenty control rats were also dispatched into LPD (n=10) and NPD (n=10) group. Serum creatinine (SCr), uric acid (SUA), glucose (BG), urea nitrogen (BUN) and 24h-urine creatinine (UCr), urea nitrogen (UUN), uric acid (UUA), albumin excretion (UAE) were measured at baseline and 3, 6, 9, 12 weeks. Hepatic expressions of 3 key enzymes for uric acid synthesis including phosphoribosyl-pyrophosphat (PRPP) synthetase-1 (PRPPS-1), PRPP amidotransferase (PPAT) and xanthine oxidase (XO) were detected by RT-PCR. Finally we analysed renal histologic alterations and inflammatory factors (TNF- $\alpha$  and VEGF) expression in renal tissue.

**Results:** 1) Diabetic rats developed into constant and high level of BG, SCr, BUN, SUA as well as 24h amounts of UCr, UUN, UUA and UAE ( $P<0.01$  from the 3rd week). 2) LPD in diabetic rats significantly decreased SUA, BG and UAE ( $P<0.01$  from the 3rd week) compared with those fed with NPD, left SCr, BUN, UCr, UUN nearly compared between 2 diet groups ( $P>0.05$  from baseline). A stepwise linear regression in which UAE served as independent variable among diabetic rats at 9th and 12th week ( $B=5.82$  and  $4.40$  respectively, both  $P<0.05$ ) showed that UUA is an independent risk factor for DN progression beside BG. 3) LPD slightly inhibit PRPPS-1 ( $5.86\pm3.32$  vs.  $6.99\pm2.14$ ), PPAT ( $9.49\pm4.41$  vs.  $13.36\pm5.67$ ) and XO ( $9.24\pm7.23$  vs.  $12.15\pm6.06$ ) expression at hepatocytes. 4) Glomeruli from diabetic rats were much larger in size than control rats ( $P<0.05$ ), mesangial cell proliferation and hyaline degeneration of tubular epithelial cell were also severe ( $P<0.05$ ), but LPD remarkably ameliorated degrees of these pathologic changes ( $P<0.05$ ). 5) Expression of TNF- $\alpha$  in tubular epithelial cell significantly decreased in diabetic rats fed with LPD ( $P<0.05$ ), while VEGF expression was comparable between all rats ( $P>0.05$ ).

**Conclusion:** LPD in STZ-induced diabetic rats significantly inhibits endogenous uric acid synthesis. This process may attenuate renal damage in these rats.

#### Characterisation of the morphological and functional features of the retinal neurodegenerative process in a murine model of spontaneous type 2 diabetes

P. Bogdanov<sup>1</sup>, A. Rodrigues-Carvalho<sup>2</sup>, L. Corraliza<sup>1</sup>, J. Garcia-Arumí<sup>2</sup>, J.A. Villena<sup>1</sup>, C. Hernández<sup>1</sup>, R. Simó<sup>1</sup>;

<sup>1</sup>CIBERDEM and Diabetes and Metabolism Research Unit, Vall d'Hebron Research Institute, <sup>2</sup>Ophthalmology Department, Vall d'Hebron Research Institute, Barcelona, Spain.

**Background and aims:** There is emerging evidence to suggest that retinal neurodegeneration is an early event in the pathogenesis of diabetic retinopathy (DR), which antedates and participates in the microcirculatory abnormalities that occur in DR. The experimental model currently used to study retinal neurodegeneration in DR is the rat with streptozotocin-induced diabetes (STZ-DM). However, it should be noted that the interpretation of the results in this model might be hampered by the neurotoxic effect of STZ. Therefore, the aim of the present study was to characterize the sequential events that are taking place in retinal neurodegeneration in a murine model that carries a mutation in the leptin receptor gene and develops spontaneous type 2 diabetes (db/db mice).

**Material and methods:** A total of 72 C57BL/6 mice were divided into two groups: non-diabetic (db<sup>+</sup>/db<sup>+</sup>) and diabetic (db<sup>+</sup>/db<sup>+</sup>). To assess the chronological sequence of the abnormalities the analysis was performed at different evolutionary stages (8, 16 and 24 weeks). The retinas were evaluated in terms of morphological (total retinal thickness, thickness of retinal layers and ganglion cell count in HE sections) and functional abnormalities [electroretinography (ERG)]. In addition, histological markers of neurodegeneration (glial activation and apoptosis) were evaluated. Glial activation was assessed by immunohistochemistry using specific antibodies against GFAP (Glial fibrillar acidic protein). Apoptosis was quantified using the TUNEL method. Furthermore, apoptosis inducing factor (AIF) was determined by immunohistochemistry.

**Results:** At week 8 glial activation was significantly higher in diabetic than in non diabetic mice ( $p<0.01$ ). In addition, a loss of 20% ( $p<0.05$ ) of ganglion cells was detected in diabetic mice. Moreover, a significant reduction of neuroretinal thickness was also observed. All these findings were more pronounced at weeks 16 and 24. ERG abnormalities were already present at week 8 in diabetic mice and worsened in parallel with histological hallmarks of neurodegeneration. Overall all these findings are very similar than those found in the early stages of DR in diabetic patients.

**Conclusion:** Our results suggest that db/db mice are an appropriate murine model for investigating the underlying mechanisms of diabetes-induced retinal neurodegeneration and for testing neuroprotective drugs.

#### IRS2 deficiency limits the effects of inhibition of protein tyrosine phosphatase 1B in IGF-IR-mediated signalling in the retina

A.I. Arroba<sup>1,2</sup>, J. Revuelta-Cervantes<sup>1,2</sup>, L. Meses<sup>3,4</sup>, Á. González-Rodríguez<sup>1,2</sup>, P. de la Villa<sup>5</sup>, D.J. Burks<sup>3,4</sup>, Á.M. Valverde<sup>1,2</sup>;

<sup>1</sup>Centro de Investigaciones Biomédicas, Madrid, <sup>2</sup>CIBERDEM, Madrid,

<sup>3</sup>Molecular and Endocrinology Laboratory, Centro de Investigación

“Príncipe Felipe”, Valencia, <sup>4</sup>CIBERDEM, Valencia, <sup>5</sup>Universidad de Alcalá de Henares, Madrid, Spain.

**Background and aims:** Mice with complete deletion of insulin receptor substrate (IRS) 2 develop type 2 diabetes. In the retina, IRS2 deficiency induced photoreceptor degeneration and apoptosis that is not rescued by normalization of glucose levels. On the other hand, protein tyrosine phosphatase 1B (PTP1B) inhibition by genetic deletion in IRS2<sup>-/-</sup> mice (double mutant IRS2<sup>-/-</sup>PTP1B<sup>-/-</sup>) restored peripheral insulin resistance and normalized glucose homeostasis. Since IGF-IR promotes survival of photoreceptors and also is a substrate of PTP1B, we aimed to investigate IGF-IR-mediated survival signalling and visual function in PTP1B<sup>-/-</sup> and IRS2<sup>-/-</sup>/PTP1B<sup>-/-</sup> in comparison to wild-type and IRS2<sup>-/-</sup> mice.

**Materials and methods:** IGF-IR tyrosine phosphorylation and Akt serine 473 phosphorylation were analyzed by western blot in organotypic retinal

explants stimulated with IGF-I. Immunohistochemistry was used to evaluate retinal structure preservation in mice at 10–12 weeks and programmed cell death was assessed by TUNEL. Visual function was evaluated by Electroretinographic (ERG) recording in mice at 5 and 10 weeks.

**Results:** IGF-IR tyrosine phosphorylation and Akt serine 473 phosphorylation increased in retinal explants stimulated for 15 min with IGF-I in a dose-dependent manner. In PTP1B<sup>-/-</sup> retinal explants, these responses increased by twofold in IGF-IR phosphorylation and by threefold in Akt phosphorylation compared to the wild-type control ( $p=0.037$  and  $p=0.04$ , respectively). Conversely, in IRS2<sup>-/-</sup> mice the response to IGF-I in Akt phosphorylation decreased compared to the wild-type control ( $p=0.04$ ). Moreover, in IRS2<sup>-/-</sup> mice PTP1B deletion (double mutant IRS2<sup>-/-</sup>/PTP1B<sup>-/-</sup>) also enhanced IGF-IR tyrosine phosphorylation ( $p=0.01$ ) but, unexpectedly, the response to IGF-I in the activation of Akt remained decreased as observed in the IRS2<sup>-/-</sup> mice. Histological evaluation revealed a significant thickness in whole retina in both IRS2<sup>-/-</sup> and double mutant IRS2<sup>-/-</sup>/PTP1B<sup>-/-</sup> mice, specifically in the outer nuclear layer (ONL) and retinal outer segments (ROS) ( $p<0.001$ ). ERG analysis showed that PTP1B deficiency did not restore normal visual function in IRS2<sup>-/-</sup> mice.

**Conclusion:** Although PTP1B deficiency significantly enhanced IGF-IR tyrosine phosphorylation in retinal explants of IRS2<sup>-/-</sup> mice, it was unable to restore Akt phosphorylation and, therefore, the structural and functional visual of these mice defects were not improved.

## 1119

### Inhibition of hypoxia-induced retinal angiogenesis in nucleoside diphosphate kinase B knockout mice

Y. Feng<sup>1</sup>, V. Butenschoen<sup>1</sup>, Y. Qiu<sup>1</sup>, H.-P. Hammes<sup>2</sup>, E. Skolnik<sup>3</sup>, T. Wieland<sup>1</sup>;

<sup>1</sup>Institute of experimental and clinical pharmacology and toxicology, Mannheim, Germany, <sup>2</sup>V. Medical Clinic, Mannheim, Germany, <sup>3</sup>Division of Nephrology, New York University Langone Medical Center, USA.

**Background and aim:** Proliferative diabetic retinopathy is characterized by inappropriate angiogenesis under hypoxia which forms neovascularizations into the vitreous arising from pre-existing retinal vessels. Nucleoside diphosphate kinase B (NDPK B) can activate heterotrimeric G proteins independently of GPCRs and thus likely contributes to a variety of physiological and pathological processes. In this study we investigated the contribution of NDPK B in hypoxia-induced retinal angiogenesis.

**Materials and methods:** Retinas of NDPK B knockout mice were assessed under conditions of physiological and pathological angiogenesis. Retinal vascular morphology under physiological condition was evaluated in the NDPK B Ko mice at postnatal day 5 (p5) and p10. To study pathological angiogenesis the NDPK B Ko mice were subjected to the model of hypoxia-induced retinopathy (OIR), i.e. new born pups were kept from p7 in an oxygen incubator with 75% O<sub>2</sub> for 5 days and then transferred to room air for another 5 days until p17. Pre-retinal angiogenesis at p17 was assessed in paraffin sections stained with PAS, whereas intra-retinal vascular angiogenesis was evaluated in whole mount retina stained with vascular markers. Expression of angiogenic growth factors in the retina was measured by quantitative PCR.

**Results:** Physiological angiogenesis in NDPK B Ko mice at p5 in the retinal superficial layer as well as at p10 in the deep capillary layer did not differ from their wild type littermates. However, deficiency of NDPK B in the mice resulted in marked reduced pre-retinal angiogenesis in the OIR model compared to wild type mice ( $p<0.05$ ). Nevertheless, there was no difference in the intra-retinal angiogenesis between NDPK B Ko and wild type mice in this model. Retinal expression of VEGF, Angiopoietin-2 and Erythropoietin was highly up-regulated in the mice subjected to the OIR model compared to the mice kept in room air from p7 to p17. However, the retinal up-regulation of these markers in the OIR model was comparable in NDPK B Ko mice and their wild type littermates.

**Conclusion:** Our data indicate that NDPK B plays an essential role in pathological but not in physiological angiogenesis. The mechanism how NDPK B regulates the VEGF dependent pathological angiogenesis requires further investigation.

## 1120

### Upregulation of rab20 expression by high glucose reduces gap junction activity and accelerated death of retinal endothelial cells

C. Stottrup, S. Roy;  
Boston University, Boston, USA.

**Background and aims:** Retinal vascular cell loss is a prominent lesion associated with diabetic retinopathy, a leading cause of vision loss in the working age population. Studies have shown that gap junction intercellular communication (GJIC) through connexin 43 (Cx43) channels is essential for cell survival and maintenance of retinal homeostasis. In this study, we examined whether high glucose compromises GJIC and induces apoptosis of retinal endothelial cells through altered expression of rab20, a potential regulator of Cx43 trafficking.

**Materials and methods:** To determine whether high glucose alters rab20 protein expression, rat retinal endothelial cells (RRECs) were grown in normal (N, 5mM) or high glucose (HG, 30 mM) medium for 7 days, and total protein isolated from these cells was analyzed for rab20 protein expression using immunoprecipitation and Western blot analysis. Increasing concentrations of rab20 siRNA were used to modulate HG-induced rab20 overexpression and determine its effects on Cx43 levels and GJIC activity. Localization and distribution of Cx43 was determined by immunostaining, GJIC activity was assessed by scrape-load dye transfer technique, and cells undergoing apoptosis were identified using TUNEL assay.

**Results:** Western blot analysis revealed that HG significantly upregulated rab20 by 30% ( $P<0.01$ ) compared to cells grown in N medium. Cells grown in HG medium and transfected with either 40 nM or 80 nM rab20 siRNA showed 43% and 82% reduction in rab20 expression, respectively, compared to rab20 expression in cells grown in HG. The relative number of Cx43 plaques at sites of contact between adjacent cells was significantly reduced in HG condition by 38% ( $P<0.05$ ) compared to cells grown in N medium. Cells grown in HG medium and transfected with 40 nM or 80 nM rab20 siRNA showed increased number of Cx43 plaques by 16% and 29%, respectively ( $P<0.05$ ) and improved GJIC activity (increased number of dye-coupled cells: 21% and 68% respectively), as compared to those grown in HG medium only. Importantly, cells grown in HG medium and transfected with rab20 siRNA showed a beneficial effect in reducing the number of apoptotic cells ( $1.5 \pm 0.6$  vs.  $7.3 \pm 1.4$ ;  $P<0.01$ ).

**Conclusion:** High glucose reduces Cx43 expression and GJIC activity in part by upregulating rab20 protein expression. siRNA mediated downregulation of rab20 may improve cell-cell communication and vascular homeostasis, and prevent HG-induced vascular cell death associated with diabetic retinopathy.

## 1121

### Endoplasmic reticulum stress leads to multiple manifestations of diabetic nephropathy and glomerular collagen deposition caused by high-fat diet

H. Shevalye, S. Lupachyk, P. Watcho, R. Stavniichuk, I.G. Obrosova;  
Mechanisms of Diabetes Complications, Pennington Biomedical Research Center, Baton Rouge, USA.

**Background and aims:** The endoplasmic reticulum (ER) plays a pivotal role in the folding and processing of newly synthesized proteins. Damage to ER and resultant ER stress lead to aberrant transcriptional regulation and gene expression, signaling, ion channel function, and metabolism. ER stress plays an important role in insulin resistance and obesity. We evaluated the role for ER stress in diabetic nephropathy (DN) and kidney disease caused by high-fat diet.

**Materials and methods:** In experiment 1, control and STZ-diabetic rats were treated with or without the chemical chaperone trimethylamine-N-oxide (TMAO), 110 mg kg<sup>-1</sup>d<sup>-1</sup>, for 12 wks (a prevention paradigm). Endpoints included 24-h urinary albumin (ELISA), 8-isoprostane (ELISA) and creatinine (colorimetry) excretion, kidney weight, glomerular podocyte counts (immunohistochemistry), mesangial volume and collagen deposition (histochemistry), renal cortex fibronectin, total and phospho-PERK, total and phospho-eIF2 $\alpha$ , BiP/GRP78, and CHOP (Western blot analysis), and protein carbonyl (ELISA) contents. In study 2, C57BL6/J mice were fed normal or high-fat (HFD) diets for 16 wks, and then maintained with or without a 4-wk treatment with salubrinal (1 mgkg<sup>-1</sup>d<sup>-1</sup> i.p.), a selective inhibitor of eIF2 $\alpha$  dephosphorylation. Endpoints included 24-h urinary albumin and 8-isoprostane excretion (ELISA), collagen deposition (histochemistry), and glomerular podocyte counts (immunohistochemistry).

**Results:** In experiment 1, diabetes-induced renal ER stress was manifested by increased phospho-PERK and phospho-PERK/total PERK ratio. Phospho-eIF2 $\alpha$ /total eIF2 $\alpha$  ratios and BiP/GRP78 levels were indistinguishable between control and diabetic rats. The diabetic condition was associated with 18% increase in CHOP level, but the difference with controls did not achieve statistical significance ( $p=0.073$ ). TMAO treatment reduced diabetes-associated albuminuria, mesangial expansion, fibronectin accumulation, and collagen deposition, in the absence of any effects on blood glucose concentrations, podocyte loss, urinary 8-isoprostane excretion, or renal cortex protein carbonyl accumulation. In experiment 2, salubrinal improved glucose tolerance and blunted glomerular collagen deposition in HFD-fed mice, without affecting albuminuria, glomerular podocyte loss, or urinary 8-isoprostane excretion.

**Conclusion:** ER stress is implicated in the development of multiple manifestations of DN and glomerular collagen deposition caused by HFD consumption. These results provide the rationale for further studies of ER stress/unfolded protein response in prediabetic and diabetic kidney disease, and identify a new therapeutic direction.

## 1122

### Rho/ROCK and p38 MAP kinase signalling pathways drive the effect of fluctuating glucose on renal fibrogenesis

S. Hadjadj<sup>1</sup>, T. Harnois<sup>2</sup>, S. Brishoual<sup>3</sup>, I. Paris<sup>4</sup>, E. Vincent-Tassin<sup>2</sup>, P.-J. Saulnier<sup>5</sup>, N. Bourmeyster<sup>6</sup>;

<sup>1</sup>Endocrinology -Diabetology, CHU Poitiers, <sup>2</sup>Endocrinology -Diabetology, CHU Poitiers, <sup>3</sup>CIC 0802, CHU Poitiers, <sup>4</sup>EA 4331, Université de Poitiers, <sup>5</sup>INSERM CIC 802, CHU Poitiers, <sup>6</sup>Institut de Physiologie et Biologie cellulaires, CHU Poitiers, France.

**Background:** Glucose fluctuations recently emerged as a possible mechanism promoting vascular complications in addition to glucose exposure. How glucose fluctuations promote renal fibrogenesis is still ill-defined.

**Materials and methods:** We used two cell models to answer this question: a cell-line derived from rat mesangial cells (NRK-49) and a primary culture of skin fibroblasts from healthy volunteers. We changed the milieu every two hours for ten hours, for two consecutive days to compare the effect of glucose concentration in the medium: normal glucose - NG - (5.6 mM), high glucose-HG- (25 mM), fluctuating glucose -FG- (alternance of 5.6 and 25 mM).

**Results:** Fluctuating glucose (FG) promoted renal fibrogenesis (Fibronectin protein expression) in both cell models compared to non-fluctuating normal and even high glucose. This effect was not related to activation of the ERK, JNK or NF $\kappa$ B pathway, while phospho-p38 MAP-kinase was significantly increased in FG conditions compared to NG and also to HG. There was a specific activation of Rho/ROCK by FG with RhoA and MyPT-1 activation. Adding P38 MAP kinase and Rho kinase inhibitor Y27632 resulted in a normalisation of fibronectin secretion with an additional effect of both pathways to reverse this phenotype.

**Conclusion:** We conclude that the effect of fluctuating glucose to promote renal fibrogenesis was evidenced in two independent models of mesangial cells and was related to p38 MAP-kinase and Rho signaling, leading to a peculiar interest of this pathway for diabetic nephropathy. The identification of the Rho/ROCK pathway as a specific activated pathway following glucose fluctuations might lead to a better understanding of diabetes complications pathophysiology.

### Histamine H<sub>4</sub> receptors are present in the kidney of diabetic rats

A.C. Rosa<sup>1</sup>, C. Grange<sup>2</sup>, A. Pini<sup>3</sup>, M.A. Katebe<sup>4</sup>, E. Benetti<sup>1</sup>, M. Collino<sup>1</sup>, G. Miglio<sup>1</sup>, D. Bani<sup>5</sup>, G. Camussi<sup>2</sup>, P.L. Chazot<sup>4</sup>, R. Fantozzi<sup>1</sup>;

<sup>1</sup>Scienza e Tecnologia del Farmaco, University of Turin, Italy, <sup>2</sup>Department of Internal Medicine, Centre for Molecular Biotechnology, University of Turin, Italy, <sup>3</sup>Department of Preclinical and Clinical Pharmacology, University of Florence, Italy, <sup>4</sup>School of Biological and Biomedical Sciences and Wolfson Institute, Durham University, UK, <sup>5</sup>Department of Anatomy, Histology and Forensic Medicine, Section of Histology, University of Florence, Italy.

**Background and aims:** Histamine, a biogenic amine that exerts its effects through the interaction with four subtypes of G-protein-coupled receptors designated H<sub>1-4</sub>, was previously suggested to be involved in diabetic-related kidney disease. While the renal expression of H<sub>1</sub> and H<sub>2</sub> receptors was

demonstrated, that of the most recently discovered H<sub>3</sub> and H<sub>4</sub> receptors was poorly investigated. The aim of this research was to investigate the expression of the H<sub>4</sub> receptors in the kidney of healthy and diabetic rats.

**Materials and methods:** Diabetes was induced in 12 out of 24 8-week-old male Wistar rats by a single i.v. injection of streptozotocin, and animals were sacrificed 6 weeks later. Kidneys were collected and processed for RT-PCR or immunohistochemistry analyses. To ascertain the renal distribution of H<sub>4</sub> receptor, colocalization experiments were performed by using tubular markers, such as aquaporin 1, 2 and 3, Na-K-Cl cotransporter 1, Tissue non-specific alkaline phosphatase and Tamm-Horsfall glycoprotein.

**Results:** Diabetic rats showed a kidney-to-body weight ratio significantly higher and a creatinine clearance decreased. The increase in urinary N-Acetyl- $\beta$ -glucosaminidase level suggested tubular dysfunction. These biochemical abnormalities were associated with clear changes in renal histology. H<sub>4</sub> receptor was expressed in the kidney of healthy rats, although at a very low level, and was profoundly upregulated in diabetic animals. Immunohistochemical detection demonstrated that H<sub>4</sub> receptor subtype was not present in the glomeruli but in the tubules, with the highest immune-positivity in the medulla. Comparing H<sub>4</sub> receptor immunostaining to that of tubular markers a close overlap in expression topology was observed only with Tamm-Horsfall glycoprotein, thus indicating that the receptor is expressed on epithelial cells of the thick ascending limb of the loop of Henlé.

**Conclusions:** The results demonstrate for the first time that H<sub>4</sub> receptor is expressed by resident renal cells of the thick ascending limb of the loop of Henlé and that the receptor is significantly overexpressed in diabetic animals, thus suggesting a possible role of this receptor in the (physio) pathogenesis of diabetic-associated renal disease.

### Investigation of the podocyte-secreted protein R3h domain containing-like in diabetic nephropathy

I. Takahiro<sup>1</sup>, M. Takemoto<sup>1</sup>, Y. Akimoto<sup>2</sup>, K. Yan<sup>3</sup>, S. Onishi<sup>1</sup>, E. Okabe<sup>1</sup>, P. He<sup>1</sup>, R. Ishibashi<sup>1</sup>, K. Kobayashi<sup>1</sup>, M. Fujimoto<sup>1</sup>, H. Kawamura<sup>1</sup>, C. Betsholtz<sup>4</sup>, K. Tryggvason<sup>4</sup>, K. Yokote<sup>1</sup>;

<sup>1</sup>Department of Clinical Cell Biology and Medicine, Chiba University Graduate School of Medicine, Japan, <sup>2</sup>Division of Microscopic Anatomy, Department of Anatomy, Kyorin University School of Medicine, Tokyo, Japan, <sup>3</sup>Department of Pediatrics, Kyorin University School of Medicine, Tokyo, Japan, <sup>4</sup>Department of Medical Biochemistry and Biophysics, Division of Matrix Biology, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Diabetic nephropathy (DN) is by far the most common cause of end-stage renal disease. However, the molecular mechanisms of DN are largely unknown. Recent discoveries of podocyte-expressed genes have considerably enhanced our knowledge of the molecular mechanism of glomerular filtration by the kidney. We previously reported the identification of a podocyte-specific transcript, R3H domain containing-like (R3hdm1), as a novel regulator of the glomerular basement membrane in EASD 2011. The aim of this study was to further analyze the functions of R3hdm1 in vivo and in vitro, particularly in DN.

**Materials and methods:** R3hdm1 mRNA was stably expressed in human embryonic kidney cells (Ad293), and protein expression was evaluated by immunohistochemistry (IHC) or western blotting (WB). R3hdm1 protein was purified using an anti-R3hdm1 antibody-conjugated column. Purified R3hdm1 protein (p-R3hdm1) was added to the cultured podocytes and endothelial cells, and the localization of R3hdm1 protein was evaluated by IHC and WB. The effects of transforming growth factor- $\beta$  (TGF- $\beta$ ) on R3hdm1 expression and function were evaluated by RT-PCR. Expression of urinary R3hdm1 protein in diabetic mice (Akita mice) was compared with that in wild-type mice.

**Results:** IHC revealed that R3hdm1 protein was mainly localized to the Golgi apparatus in the cytoplasm. WB analyses detected two bands (approximately 33 and 35 kDa) in the cytoplasm. WB analyses also revealed R3hdm1 protein as a 20-kDa protein in the conditioned medium from R3hdm1-overexpressing Ad293 cells but not in the medium from control cells. These results indicated that R3hdm1 proteins were posttranscriptionally modified, processed, and secreted from the cells. When we added p-R3hdm1 to the cultured podocytes and endothelial cells, R3hdm1 protein mainly localized to the nuclei of the cells, without increasing R3hdm1 mRNA expression. TGF- $\beta$  has been reported to play major roles in DN. Therefore, we evaluated the effects of TGF- $\beta$  on R3hdm1 expression and function. TGF- $\beta$  increased the expression

of R3hdml in cultured podocytes at the mRNA and protein levels and that of fibronectin mRNA in podocytes. In the absence of R3hdml, TGF- $\beta$  increased the expression of fibronectin even further. These results suggested that the expression of R3hdml was regulated by TGF- $\beta$  and R3hdml negatively regulated TGF- $\beta$  signaling. Finally, we investigated the expression of R3hdml proteins in diabetic animals and found that its expression was significantly increased in diabetic animals compared with that in wild-type controls.

**Conclusion:** We identified R3hdml as a novel podocyte-specific gene. R3hdml protein is secreted from podocytes, and its expression is increased in DN. R3hdml might negatively regulate TGF- $\beta$  signaling. Therefore, R3hdml may be useful as a novel DN biomarker and/or a new drug target for DN.

## 1125

### IRS 2 is an essential molecule for insulin signalling in renal cells

B. Santamaría<sup>1,2</sup>, A. Gonzalez-Rodriguez<sup>1,2</sup>, G.I. Welsh<sup>3</sup>, L. Ni<sup>3</sup>, L. Hale<sup>3</sup>, M.A. Saleem<sup>3</sup>, R.J. Coward<sup>3</sup>, A.M. Valverde<sup>1,2</sup>;

<sup>1</sup>Instituto de Investigaciones Biomédicas Alberto Sols, CSIC-UAM,

<sup>2</sup>CIBERDEM, Madrid, Spain, <sup>3</sup>Academic Renal Unit, School of Clinical Sciences, University of Bristol, UK.

**Background and aims:** Diabetic nephropathy is the commonest cause of end-stage renal failure in the world. Its natural history is dominated by progressive albuminuria. Recently it has been demonstrated that podocyte insulin resistance may be implicated in this diabetic complication. Podocytes are crucial in maintaining integrity of the glomerular filtration barrier and preventing albuminuria. On this basis, we investigated the role of the IRS 2 in the development of diabetic nephropathy and specifically if IRS 2 affects insulin signalling in kidney function.

**Materials and methods:** We have used an *in vivo* and *in vitro* approach to study the role of IRS2 in the podocyte of the glomerulus. Initially we studied the renal phenotype of whole body IRS2 deficient mice. We then generated conditionally immortalised murine podocyte cell lines from these mice using a temperature sensitive SV40 large T antigen construct to study its role in insulin signalling in this cell.

**Results:** IRS2-deficient (IRS2<sup>-/-</sup>) animals present defects in both insulin action and insulin production. By 12 weeks of age, a proportion of IRS2<sup>-/-</sup> mice are diabetic and, therefore, they exhibit a severe hyperglycemia (glucose levels >400 mg/dl) and develop significant levels of albuminuria. They exhibit mild glomerular abnormalities (matrix accumulation) using light microscopy and have podocyte abnormalities using electron microscopy with significant foot process widening. Fascinatingly the immortalised cells from these mice are profoundly insulin resistant in comparison to podocytes derived from age-matched wild-type mouse controls (insulin-stimulated increase in glucose uptake 150 % WT vs 100 % IRS2 KO). They also have significantly impaired AKT (45 % PKB) signalling in response to insulin and exhibit impaired GLUT4 membrane translocation. They have comparable levels of IRS1 in comparison to controls.

**Conclusion:** These results show suggest the critical importance of IRS2 in maintaining glomerular function in glomeruli being critical for normal kidney function. Furthermore, the *in vitro* studies demonstrate that IRS2 is a critical node for insulin signalling in the podocytes.

## 1126

### Endothelial function and myogenic constriction of small renal arteries as determinants of diabetic kidney damage in Zucker diabetic fatty rats

H. Buikema, M. Hamidi Shishavan, S. Landheer, L.E. Deelman,

R.H. Henning;

Clinical Pharmacology, University Medical Center Groningen / University of Groningen, Netherlands.

**Background and aims:** Endothelial dilatory function (EDF) and smooth muscle myogenic constriction (MC) are important mechanisms in autoregulation of renal blood flow and glomerular filtration rate (GFR), but also in the protection of renal structures from systemic blood pressure. Consistent with that, we found interindividual variability in intra-renal EDF and MC to predict and precede kidney damage. Here we studied intra-renal EDF and MC as predictors of renal damage development in obese Zucker Diabetic Fatty rats (ZDF).

**Materials and methods:** ZDF (n=14) underwent unilateral nephrectomy (UNx) at 7 weeks of age. Small arteries were isolated from the extirpated kid-

ney and studied *in vitro* for EDF to acetylcholine and pressure-induced MC (in endothelium-denuded segments). Baseline EDF- and MC-values were ranked from low-to-high for individual rats (1-14), and an EDF\*MC interaction ranking was calculated additionally. Rats were followed until 10 weeks thereafter when final metabolic and renal function parameters were assessed and blood pressure determined. Baseline renal vascular function (EDF and MC solitary ranking, and EDF\*MC interaction ranking) was analysed to predict the development of proteinuria following UNx by means of correlation analysis.

**Results:** Metabolic and renal parameters confirmed that ZDF were at pre-diabetic state with intact renal function when baseline renal vascular function was assessed. Ten weeks later, blood glucose had increased to 16.8±2.3 mmol/L, HbA1c to 5.6±0.3%, and 24h urinary protein excretion to 188.4±20.5 mg, while systolic blood pressure (120±3 mmHg) was still within normotensive range. Correlation analysis showed that EDF\*MC interaction ranking was positively correlated with baseline GFR ( $r^2=0.47$   $p=0.04$ ), suggesting it to be an *in vitro* derivative of *in vivo* renal vascular function. Furthermore, baseline EDF\*MC interaction ranking (but not EDF and MC solitary ranking) inversely correlated with the degree of proteinuria development following UNx in ZDF rat ( $r^2=-0.47$ ,  $p=0.03$ ).

**Conclusion:** The findings demonstrate that unlike in models of hypertension related kidney disease, EDF and MC as solitary components of renal vascular function did not predict the individual's susceptibility to renal damage in diabetic conditions in the absence of high blood pressure. However, the interaction between the both - which we calculated as the EDF\*MC interaction ranking - significantly correlated to proteinuria development as an indices of renal damage following UNx in individual ZDF rat. EDF\*MC interaction ranking may represent a new an *in vitro* derivative of *in vivo* renal vascular function with predictive-value for susceptibility to renal damage development in non-hypertensive conditions.

## PS 097 Predicting nephropathy and retinopathy

1127

### Association of monocyte chemoattractant protein-1 (MCP-1) 2518 A/G polymorphism with a proliferative diabetic retinopathy (PDR) in Korean type 2 diabetes

T. Oh<sup>1</sup>, H.-J. Jeon<sup>1</sup>, Y.-H. Lee<sup>2</sup>;

<sup>1</sup>Internal Medicine, <sup>2</sup>Biochemistry, Chungbuk National University, Cheongju, Republic of Korea.

**Background and aims:** Monocyte chemoattractant protein-1(MCP-1) is a chemokine that exert several effects on monocytes, including the production of superoxide anion, cytokine production, and adhesion molecule expression. It has been reported that hyperglycemia increases MCP-1 production in vascular endothelial cells and retinal pigmented epithelial cells. In this study, we evaluated the association of the MCP-1 2518 A/G polymorphism with proliferative diabetic retinopathy (PDR) in Korean type 2 diabetes.

**Materials and methods:** We conducted a case-control study, which enrolled 590 patients with Korean type 2 diabetes. Diabetic retinopathy was defined by the presence of characteristic changes, including hemorrhages, exudates or history of laser photocoagulation or vitrectomy. Genotyping of MCP-1 2518 A/G polymorphism was performed using polymerase chain reaction followed by digestion with Pvu II restriction enzyme.

**Results:** The prevalence of the MCP-1 2518 A/G genotype was as follows: AA, 13.2%; AG, 47.1%; GG, 39.7%; and the genotype distribution was in Hardy-Weinberg equilibrium. In terms of severity of diabetic retinopathy, the prevalence of proliferative diabetic retinopathy (PDR) was significantly higher in subjects with AA genotype compared with those with AG or GG genotypes [35.9%(28/78) vs.22.3%(114/512),  $P=0.009$ ]. The prevalence of any other diabetic micro or macro complications such as neuropathy, nephropathy, and cardiovascular events was not different according to the MCP-1 2518 A/G genotype.

**Conclusion:** Our results suggest that the AA genotype of MCP-1 2518 A/G polymorphism could be a susceptibility gene for the PDR in Korean type 2 diabetic patients.

### Progression of diabetic nephropathy and genetic variability in the renin-angiotensin-aldosterone system: evidence for pharmacogenetic effects?

V. Bartakova<sup>1</sup>, D. Maluskova<sup>2</sup>, K. Kuricova<sup>1</sup>, V. Tanhauserova<sup>1</sup>, L. Pacal<sup>1</sup>, J. Belobradkova<sup>3</sup>, J. Muzik<sup>2</sup>, T. Pavlik<sup>2</sup>, J. Svojanovsky<sup>4</sup>, D. Krusova<sup>4</sup>, J. Rehorova<sup>3</sup>, K. Kankova<sup>1</sup>;

<sup>1</sup>Dept. of Pathophysiology, Masaryk University Brno, Faculty of Medicine,

<sup>2</sup>Institute of biostatistics and analyses, Masaryk University Brno, Faculty of Medicine and Faculty of Science, <sup>3</sup>Dept. of Gastroenterology, Faculty Hospital Brno-Bohunice, <sup>4</sup>Dept. of Internal Medicine, St. Anne's Faculty Hospital, Brno, Czech Republic.

**Background and aims:** Pathological over-activation of renin-angiotensin-aldosterone system (RAAS) as the key pathogenic mechanism of diabetic nephropathy (DN). Pharmacological blockade of RAAS represents main renoprotective treatment of DN. Several single nucleotide polymorphisms (SNPs) were shown to influence interindividual variability in RAAS (e.g circulating levels of RAAS compounds and enzyme activities) and could hypothetically also modify therapeutic effect of RAAS blockers. We aimed to study contribution of genetic variability in RAAS to the progression of DN and other adverse outcomes of diabetes taking into account RAAS blocking treatment in a quantitative manner.

**Materials and methods:** A total of 391 diabetic patients with variable stage of kidney disease were prospectively followed for a median of 39 (IQR 20–58) months. We considered following end-points: (1) progression of DN, (2) major cardiovascular event (MCVE, non fatal myocardial infarction or stroke) and (3) all-cause mortality. Selected SNPs were genotyped using PCR: angiotensin converting enzyme (I/D ACE), angiotensinogen (ATG M235T), angiotensin II type I receptor (ATRI A1166C), aldosterone synthase (CYP11B2-344T/C), hydroxysteroid dehydrogenase (HSD11B1 8355T/insA, HSD11B2 G534A) and mineralocorticoid receptor (MR G3514C, MR A4582C). Subjects were receiving following antihypertensive treatment: (1) angiotensin converting enzyme inhibitors only (ACEi, 36%), (2) angiotensin II receptor

blockers only (ARBs, 14%), (3) both ACEi and ARBs (23%) and (4) no antihypertensive treatment (27%). Cumulative dose during the follow-up was expressed as units of Captopril for ACEi and units of Losartan for ARBs.

**Results:** We found significant differences in mortality between carriers of genotypes of CYP11B2 -344T/C and ATG M235T (log-rank test,  $P=0.05$  and  $0.037$ , respectively) in univariate time-to-event analysis. Using Cox regression model carriers of the combination of risk genotypes exhibited significant difference in mortality (HR 2.70 95% CI 1.34-5.43,  $p=0.005$ ) without significant contribution of treatment parameters.

**Conclusion:** We identified significant genetic contribution of genetic variability in the RAAS to all-cause mortality of diabetic patients however no evidence of pharmacogenetic effects. More thorough analysis are currently under way.

### The association of the 174G>C polymorphism on interleukin 6 gene with diabetic nephropathy in patients with type 2 diabetes mellitus

S. Papaoikonomou<sup>1</sup>, N. Tentolouris<sup>1</sup>, D. Tousoulis<sup>2</sup>, D. Papadogiannis<sup>1</sup>, A. Miliou<sup>2</sup>, G. Hatzis<sup>2</sup>, N. Papageorgiou<sup>2</sup>, A. Kokkinos<sup>1</sup>, N. Katsilambros<sup>1</sup>, C. Stefanadis<sup>2</sup>;

<sup>1</sup>1st Department of Propaedeutic and Internal Medicine, University of Athens Medical School, Laiko General Hospital, <sup>2</sup>1st Cardiology Department, University of Athens Medical School, Hippokration General Hospital, Athens, Greece.

**Background and aims:** Chronic inflammatory processes are thought to play a key role in the development of microvascular complications in type 2 diabetes mellitus. C-reactive protein (CRP) is a marker of systemic inflammation and is associated with sub-clinical measures of atherosclerosis. Microalbuminuria and subsequent progression to proteinuria and nephropathy is associated with increased oxidative stress and inflammatory cytokines, but whether common polymorphisms of inflammatory genes are associated with levels of albumin excretion and progression of nephropathy are still unknown. The aim of the present study was to examine the association of 174GC polymorphism of interleukin-6 (IL6) gene with diabetic nephropathy in patients with type 2 diabetes mellitus (T2DM).

**Materials and methods:** The study population consisted of 431 patients with T2DM (mean age  $66.5 \pm 9.96$  years, male  $n=218$ , female  $n=213$ ). The IL6174GC polymorphism was detected by polymerase chain reaction and appropriate restriction enzyme digestion (SFANI). Hs-CRP was assayed by particle-enhanced immunonephelometry and 24h albumin excretion was measured by analytical methods. Diabetic nephropathy was defined as presence of microalbuminuria and/or proteinuria.

**Results:** The genotype distribution was 49.1% GG, 26.8% GC and 24.1% CC, with no significant gender difference. Hs-CRP levels (mg/l) did not differ among the three genotypes. The CC homozygotes had lower albumin excretion (mg/24h) in comparison with the GC genotype, CC:  $8.9(4.0-20.9)$  vs GC:  $21.95(9.1-53.35)$ , ( $p=0.004$ ). Participants with the GC genotype tended to have more frequently nephropathy than those with the GG and the CC genotype (presence/absence of nephropathy; GC:  $(44.55/53.6\%)$  vs GG:  $(35.1\%/60.4\%)$  and CC:  $(28.3\%/66.7\%)$  genotypes, ( $p=0.071$ ). Multivariate logistic regression analysis demonstrated that the CC homozygotes had lower odds to have nephropathy in comparison with the GC genotype (odds ratio: 0.51, 95% confidence intervals=0.28-0.91,  $p=0.024$ ). This association remained significant after adjustment for gender, age, duration of diabetes, body mass index, smoking, hypertension, lipids, HbA1c and glomerular filtration rate ( $p=0.014$ ).

**Conclusion:** The IL6174GC polymorphism affects the levels of albumin excretion and the development of nephropathy in patients with T2DM, but not the hs-CRP levels. Specifically, the CC homozygotes have lower levels of 24h albumin excretion and are protected from the presence of nephropathy in comparison with the GC genotype.

## 1130

**Mannose-binding lectin (MBL) genotype associated with all-cause mortality in type 1 diabetes**J.A. Østergaard<sup>1</sup>, M.S. Lajer<sup>2</sup>, P. Rossing<sup>2</sup>, A. Flyvbjerg<sup>1</sup>, L. Tarnow<sup>2,3</sup>, T.K. Hansen<sup>1</sup><sup>1</sup>Dept. of Endocrinol. and Int. Med. and Med. Res. Labs., Aarhus University Hospital, <sup>2</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>3</sup>Aarhus University, Denmark.

**Background and aims:** Mannose-binding lectin (MBL) can initiate the complement system by carbohydrate recognition. MBL levels vary many-fold between subjects due to polymorphisms. Type 1 diabetes patients have higher MBL level than healthy subjects and high level MBL-genotypes and MBL concentrations are associated with risk of micro- and macrovascular complications. However, the precise link between MBL and mortality and cardiovascular disease remains unresolved.

**Materials and methods:** We studied effects of MBL-genotype on mortality by following 371 type 1 diabetes patients for 12 years (197 with diabetic nephropathy, 174 with normoalbuminuria). MBL genotypes were divided into high level or low level MBL-genotype by promoter and exon 1 polymorphisms.

**Results:** During follow-up, 97 patients died (78 with nephropathy). All-cause mortality was significantly higher in patients with high level MBL-genotypes compared with low level MBL-genotypes, hazard ratio 1.6 (95% CI 1.1–2.5),  $P=0.018$  by Cox regression analysis including baseline  $HbA_{1c}$  as covariate. The effect of genotype was not modified by  $HbA_{1c}$ . There was a weak positive correlation between baseline serum MBL and  $HbA_{1c}$  in all patients (correlation coefficient 0.10,  $P=0.048$ ) and in patients with high level MBL-genotype (correlation coefficient 0.33,  $P<0.0001$ ). A four-step variable with high level or low level MBL-genotype in combination with  $HbA_{1c}$  above or below the median (9.0%) significantly described all-cause mortality rates (Figure 1), log rank  $P=0.0015$ . Interestingly, hazard ratios did not differ between patients with poor glycaemic control and high level MBL-genotype and patients with better glycaemic control and low level MBL-genotype. By contrast, the mortality in the high level MBL-genotype/high  $HbA_{1c}$  group was 37% during follow-up, compared to 15% in the low level MBL-genotype/low  $HbA_{1c}$  group; hazard ratio 3.2 (CI 1.7–5.9),  $P<0.001$  by unadjusted Cox regression analysis. After adjustment for age, sex, smoking, systolic blood pressure, cholesterol and diabetic nephropathy, the hazard ratio was 2.0 (1.1–3.8),  $P=0.032$ .

**Conclusion:** Our findings demonstrate a significant independent impact of MBL-genotype on all-cause mortality in the same order of magnitude as poor glycaemic control.

## 1131

**Urinary adiponectin concentration is associated with microalbuminuria in glucose intolerance patients**

W. Jeon, C. Park, S. Park, E. Rhee, W. Lee, K. Oh, S. Park;

Endocrinology and Metabolism, Kangbuk Samsung Hospital, Seoul, Republic of Korea.

**Background and aims:** Inverse relationship between serum adiponectin and insulin resistance or type 2 diabetes mellitus has been reported. This study aimed to investigate the role of urinary adiponectin on glucose homeostasis and albumin level in the urine.

**Materials and methods:** Six hundred twenty subjects (Prediabetes subjects=144, type 2 diabetes mellitus subjects=476) were participated in this study. The level of urine adiponectin was measured by enzyme linked immunosorbent assay (ELISA) kit (Adipogen, Korea). Urinary albumin excretion was assessed by ratio of urinary albumin to creatinine (ACR). Insulin resistance was determined by homeostasis model assessment index (HOMA-IR).

**Results:** Urinary adiponectin levels were significantly higher in patients with type 2 diabetes mellitus than prediabetes subjects ( $P=0.027$ ) and similar to those in subjects with microalbuminuria compared to normoalbuminuria participants ( $P<0.001$ ). Urinary adiponectin levels were positively correlated with age, fasting plasma glucose, post-prandial glucose,  $HbA_{1c}$ , triglyceride, HOMA-IR, blood pressure, hs-CRP, brachial-ankle pulse wave velocity, and the ratio of urinary albumin to creatinine (ACR) (all  $P<0.05$ ). Urinary adiponectin levels were significantly associated with risk of type 2 diabetes mellitus (OR 1.024, 95% CI 1.001–1.048,  $P=0.037$ ). Also, the adiponectin amount in urine showed significantly higher risk for microalbuminuria after adjusting age, sex and other metabolic parameters (OR 1.030, 95% CI 1.013–1.047,  $P<0.001$ ).

**Conclusion:** In conclusion, urinary adiponectin concentration is positively associated with microalbuminuria. Therefore, we suggest that measurement of urinary adiponectin level is an independent indicator of microalbuminuria.

## 1132

**Proximal and distal tubular markers in patients with type 1 diabetes**

B. von Scholten, S. Theilade, M. Lajer, C. Joergensen, S.E. Nielsen, P. Rossing; Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** The isoenzymes alpha and pi glutathion S-transferase ( $\alpha$ -GST and  $\pi$ -GST) are secreted from the proximal and distal part of the renal tubules, respectively. Levels of both enzymes were found elevated in type 2 diabetes and acute tubular damage, with further increase of  $\pi$ -GST with increasing urinary albumin excretion, whereas in another study elevated  $\alpha$ -GST indicated preserved renal function. The aim of this study was to evaluate if levels of  $\alpha$ -GST and  $\pi$ -GST were elevated and associated with albuminuria and renal function in patients with type 1 diabetes.

**Materials and methods:** Cross sectional study including 187 patients and 16 control persons. Patients were (mean $\pm$ SD) 53 $\pm$ 14 years, with 29 $\pm$ 18 years diabetes duration, 123(66%) were male. Normoalbuminuria (300mg/24-hour) in 70(37%) of patients. Controls were 40 $\pm$ 12 years old and 11(69%) were male. Morning spot urines were analysed with ELISA methods (Argutus Medical).

**Results:** Median(range)  $\pi$ -GST in controls was 9.4(1.5–77.5) ug/l, in normoalbuminuric 9.3(0.3–172.0) ug/l, in microalbuminuric 9.0(0.3–340) ug/l and in macroalbuminuric 6.1(0.3–138) ug/l ( $p=0.191$ ). In controls  $\alpha$ -GST was 9.3(0.3–50.5) ug/l, and in patients with normoalbuminuria 4.3(0.3–50.8) ug/l, with microalbuminuria 2.5(0.3–170.8) ug/l and with macroalbuminuria 3.0(0.3–18.3) ug/l ( $p=0.025$ ).  $\pi$ -GST was lower in men vs. women (7.5(0.3–90.3) vs. 15.0(0.8–340.0);  $p<0.05$ ). When comparing all patients to controls, levels of  $\alpha$ -GST were 3.0(0.3–170.8) ug/l in the patient group and 9.3(0.3–50.5) in the control group, while levels of  $\pi$ -GST were 8.8(0.3–340.0) ug/l in the patient group and 9.4(1.5–77.5) ug/l in the control group.  $\alpha$ - and  $\pi$ -GST correlated with each other ( $r=0.357$ ;  $p<0.001$ ), and  $\alpha$ -GST correlated with  $HbA_{1c}$  ( $r=0.179$ ;  $p=0.001$ ) and eGFR ( $r=0.169$ ;  $p=0.016$ ); whereas  $\pi$ -GST correlated with none of these covariates ( $p>0.05$ ). Neither GST isoenzymes correlated with age, duration of diabetes, total cholesterol, 24-hour SBP or urinary albumin excretion rate ( $p>0.05$ ).

**Conclusion:** Urinary levels of the tubular damage marker  $\pi$ -GST were similar in controls and patients with or without elevated u-albumin, whereas urinary levels of  $\alpha$ -GST were lower in diabetes and decreased further with increasing albuminuria state or impaired renal function. These findings in

chronic renal damage are in contrast to the findings in acute tubular damage with increased levels of the markers.

Clinical Trial Registration Number: NCT01171248

## 1133

### Urinary exosomal microRNA signature in incipient diabetic nephropathy

F. Barutta, M. Tricarico, A. Corbelli, S. Pinach, S. Grimaldi, G. Bruno, M. Rastaldi, P. Cavallo Perin, G. Gruden;  
Department of Internal Medicine, University of Turin, Italy.

**Background and aims:** Diabetic nephropathy (DN) is the leading cause of end-stage renal failure in the Western World. MicroRNAs (miRNAs) are a class of small (20–22 nucleotides) non-protein-encoding RNAs that regulate gene expression via suppression of target mRNAs and have a critical role in many pathophysiological processes. MiRNAs are present in body fluids in a remarkable stable form as packaged in microvesicles of endocytic origin, named exosomes. Circulating miRNAs can display unique expression profiles in pathological conditions, suggesting that distinctive miRNA signatures may be exploited as diagnostic/prognostic tools. MiRNAs are also found in the urine and, in the present study, we compared miRNA expression profile of urinary exosomes in type 1 diabetic patients (DM1) with and without incipient DN.

**Materials and methods:** Urine were collected overnight from DM1 with and without microalbuminuria (n=10 per group), comparable for age, sex, diabetes duration, and HbA<sub>1c</sub>. Urinary exosomes were isolated from pre-cleared urine by ultracentrifugation. Exosomes quality and purity was assessed by electron microscopy, immunoblotting, (presence/absence: HSP70, alix, calnexin), and spectrophotometry. Exosomal total RNA was extracted, reverse-transcribed and pre-amplified. The Human Taqman miRNA Arrays Card A (Applied Biosystem) was used to performed initial screening of 376 miRNAs expression in 2 micro- and 2 normoalbuminuric patients. Among differentially expressed miRNA with Ct values ≤ 35 (SDS software), five miRNAs were selected on the basis of “in silico” analysis and their expression measured in all samples by real-time PCR.

**Results:** Vesicles were <100 nm in size with a mode of 35–40 nm, showed a characteristic cup-shaped morphology at the electron microscopy, and expressed both the exosome markers HSP70 and Alix, while were negative for calnexin, an endoplasmic reticulum protein. Electropherograms of extracted RNA showed that exosomes were highly enriched in small RNA species, including miRNAs, whereas no ribosomal RNA was detected. MiRNA expression profiling identified 245 miRNAs expressed in urinary exosomes from DM1 patients of which 88 miRNAs were downregulated and 48 upregulated. In silico analysis revealed that 5 differently expressed miRNAs were expressed by glomerular cells (mesangial cells: miR-145; podocytes: miR-155, miR-424; endothelial cells: miR-130a miR-199a-5p). Validation of profiling results demonstrated that miR-130a, miR-199a-5p, miR-145 expression was significantly higher, while miR-155 and miR-424 significantly lower in micro- than in normoalbuminuric patients (p<0.05).

**Conclusion:** These results show that the expression of urinary exosomal miRNAs differs in DM1 with and without incipient DN and may represent an innovative diagnostic/prognostic tool.

## 1134

### Activation of CD40/CD40 ligand system is associated with nephropathy in type 1 diabetic patients

V.V. Klimontov<sup>1</sup>, I.A. Bondar<sup>1</sup>, E.M. Parfentjeva<sup>1</sup>, V.V. Romanov<sup>2</sup>, A.P. Nadeev<sup>1</sup>;

<sup>1</sup>Novosibirsk State Medical University, <sup>2</sup>Laboratory INVITRO, Novosibirsk, Russian Federation.

**Background and aims:** The changes in extracellular matrix remodeling and chronic low-grade inflammation are believed to play an important role in diabetic nephropathy (DN) pathogenesis. It has been shown that some inflammatory and fibrogenic pathways in the kidneys involve CD40 receptor/CD40 ligand (CD40L or CD154) signalling. Expression CD40 and CD40L has been found on a wide variety of cells, including lymphocytes and macrophages, endothelial, mesangial and tubular epithelial cells. CD40 expression on non-haematopoietic cells is upregulated in inflammatory contexts, suggesting that this receptor has an important role in vasculature and fibrosis. The aim of

our study was to assess the relationship between CD40-CD40L system and development of nephropathy in type 1 diabetic patients.

**Materials and methods:** 64 patients with type 1 diabetes, 32M/32F, age 16–49 years, were examined. 25 patients had normal albumin excretion rate (group DN0), 30 ones were microalbuminuric (group DN1) and 9 patients had macroalbuminuria (group DN2). The urinary excretion of CD40, soluble form of CD40L (sCD40L), as well as excretion of the molecules involved in inflammation and matrix remodeling, namely monocyte chemoattractant protein-1 (MCP-1), type IV collagen, transforming growth factor β1 (TGF-β1) and plasminogen activator inhibitor-1 (PAI-1), was determined by ELISA. Control group (C) comprised of 10 healthy subjects. Kidney biopsy was performed in 7 normoalbuminuric and 13 microalbuminuric patients. Data are presented as median, percentile 25–75.

**Results:** CD40 excretion was increased in all diabetic patient groups as compared to control (DN0: 157.1, 117.5–240.3, p=0.0006; DN1: 193.4, 144.5–222.3, p=0.0004; DN2: 337, 290.2–374.8, p=0.0004; C: 68.2, 37.6–105.8 pg/μmol creatinine). sCD40L excretion exceeded control in micro- and macroalbuminuric patients only (DN0: 0.16, 0.09–0.24, p=0.4; DN1: 0.22, 0.13–0.44, p=0.01; DN2: 0.23, 0.16–0.47, p=0.03; C: 0.12, 0.08–0.18 pg/μmol creatinine). CD40 and sCD40L correlated significantly with albuminuria (r=0.41 and r=0.42 respectively). CD40 excretion was related to the volume of renal interstitium (r=0.38), meanwhile sCD40L correlated with tubular basement membrane width (r=0.35). Patients with micro- and macroalbuminuria had increased excretion of MCP-1 (p=0.04 and p=0.005 respectively), type IV collagen (p=0.04 and p=0.0008), TGF-β1 (p=0.01 and p=0.004) and PAI-1 (p=0.02 and p=0.006). Significant correlations were found between CD40, sCD40L and excretion of MCP-1 (r=0.45 and r=0.42), type IV collagen (r=0.55 and r=0.34), TGF-β1 (r=0.5 and r=0.86) and PAI-1 (r=0.45 and r=0.9 respectively).

**Conclusion:** The activation of CD40/CD40L system is associated with development of nephropathy in type 1 diabetic patients. Inducing of chronic inflammation and inhibiting the extracellular matrix catabolism in the kidneys, CD40-CD40L interaction may contribute to development of renal fibrosis in diabetes.

### Assessment of urinary L-FABP predictive value as a biomarker for diabetic nephropathy in type 1 diabetes

N.M. Panduru<sup>1,2</sup>, C. Forsblom<sup>2,3</sup>, L.M. Thorn<sup>2,4</sup>, M. Saraheimo<sup>2,4</sup>, A. Bierhaus<sup>5</sup>, P.M. Humpert<sup>6</sup>, P.-H. Groop<sup>3,2</sup>, on behalf of the FinnDiane Study Group;

<sup>1</sup>2nd Pathophysiology Department, “Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania, <sup>2</sup>Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, Finland, <sup>3</sup>Division of Nephrology, Department of Medicine, Helsinki University Central Hospital, Finland, <sup>4</sup>Helsinki University Central Hospital, Division of Nephrology, Department of Medicine, Finland, <sup>5</sup>Department of Medicine and Clinical Chemistry, University of Heidelberg, Germany, <sup>6</sup>Stoffwechselzentrum Rhein Pfalz, Mannheim, Germany.

**Background and aims:** Diabetic nephropathy (DN) has mainly been considered a glomerular disease, although tubular dysfunction may also play a role in its pathogenesis. Tubular markers like urinary L-FABP could thus be of potential interest for screening and diagnosis of DN. The aim of this study was to assess the predictive value and the potential clinical benefits of using this new marker at any stage of DN.

**Materials and methods:** At baseline, out of 2246 patients with type 1 diabetes 1549 had normal AER, 334 microalbuminuria and 363 macroalbuminuria. In addition, 208 non-diabetic subjects were studied. Patients were followed for a median of 5.8 years (95% CI 5.7 - 5.9) during which 112 patients progressed from normo- to microalbuminuria, 46 from micro to macroalbuminuria and 78 from macroalbuminuria to ESRD. Urinary L-FABP levels were measured by ELISA and normalized with u-creatinine, while other biochemical blood and urinary tests were performed by standard methods. Separate Cox proportional hazard models for the progression at every stage of DN were constructed and used to evaluate the predictive value of uL-FABP alone and after adjustment with AER. The clinical benefit of using uL-FABP alone or together with AER was assessed by ROC analyses.

**Results:** In a cross-sectional analysis, uL-FABP increased with worsening nephropathy stage (normo 0.039 vs micro 0.091 vs macro 0.504 μg/μmol, p<0.0001) and was higher in patients with normal AER than in non-diabetic subjects (0.0391 [95% CI 0.036 - 0.044] vs 0.0148 μg/μmol [0.007 - 0.020], p<0.0001). In Cox regression analyses, uL-FABP was an independent predic-

tor of progression at all stages of nephropathy. As would be expected, ROC curves for the prediction of progression (defined by albuminuria) were significantly larger for AER than for uL-FABP, except for patients with baseline macroalbuminuria, in whom the areas were similar. When we added uL-FABP on top of AER in the models, there was a trend towards improvement of risk prediction ( $p=0.09$ ) between  $AUC_{uL-FABP+AER}$  (0.786 [95% CI 0.765 - 0.807]) and  $AUC_{AER}$  (0.778 [0.756 - 0.799]) in normoalbuminuric patients.

**Conclusion:** Urinary L-FABP is a novel and independent predictor for progression of diabetic nephropathy irrespective of the disease stage. It may add some clinical benefit when used together with AER for identification of normoalbuminuric patients that will progress to microalbuminuria.

### Total plasmalogenes level in blood plasma and erythrocytes' membranes in patients with diabetic retinopathy

N. Akhrarova<sup>1,2</sup>, A. Tashmanova<sup>1,3</sup>, A. Alieva<sup>1,3</sup>, A. Tsoy<sup>1</sup>, Z. Shamansurova<sup>1,2</sup>, T. Saatov<sup>2,3</sup>,

<sup>1</sup>Republican Specialized Scientific-practical Medical Centre of Endocrinology, <sup>2</sup>Institute of Biochemistry of Academy of Sciences of the Republic of Uzbekistan, <sup>3</sup>Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

**Background and aims:** Diabetes mellitus (DM) is accompanied with carbohydrates, proteins, and lipids disturbances in blood and tissues. The recent studies showed decrease of the level of total plasmalogenes in blood plasma (BPP) and erythrocytes' membranes (EMP) in both type 1 (DM1) and type 2 DM (DM2) patients with diabetic peripheral neuropathy with increasing of DM severity. In this investigation we aimed to study the level of BPP and EMP in DM patients depending on severity of diabetic retinopathy (DR).

**Materials and methods:** The BPP and EMP level measured in 117 DM patients (63 with DM1 and 54 with DM2) and in 24 healthy subjects (HS). In all observed persons fasting and postprandial glycaemia, HbA<sub>1c</sub> level, total phospholipids level in plasma (PP) and erythrocyte membranes (PE) were measured. The BPP and EMP detection was based on measure of vinyl ether linkage. The DR degree was defined according to WHO criteria (2002) on ophthalmologist eye examination, where in 37 patients registered non-proliferative DR (DR1), in 31 - pre-proliferative DR (DR2), and in 26 - proliferative DR (DR3), and 23 patients with DM had no signs of DR (DR0).

**Results:** HbA<sub>1c</sub> level was increased in patients with DM1 (7.4%,  $p<0.01$ ) and DM2 (9.3%,  $p<0.001$ ) comparing to the HS (5.5%) suggesting poor control of diabetes. PP level did not differ from HS, while EP level was decreased in patients with DM1 on 9.8% ( $p<0.01$ ) and DM2 on 11.2% ( $p<0.001$ ) in comparison to HS suggesting lipids disturbances on cell plasma membrane. BPP and EMP level was significantly decreased comparing to HS on 49.8% ( $p<0.001$ ) and 53.9% ( $p<0.001$ ) in DM1, and on 20.0% ( $p<0.001$ ) and 19.8% ( $p<0.001$ ) in DM2, accordingly. The analysis found the negative linkage between DR severity and BPP and EMP levels, where at higher degree of DR, BPP and EMP levels were more decreased. BPP and EMP levels in patients with DR 2 and 3 were decreased on 6.0% and 7.0% comparing to DR0. This result together with recently obtained in patients with neuropathy also indicate the relationship between cell plasma membranes lipids abnormality and severity of diabetes complications.

**Conclusion:** In DM patients with increasing of DR severity BPP and EMP levels decreased suggesting association between plasma membranes lipids abnormalities and diabetes complications.

## PS 098 Diabetic nephropathy and retinopathy screening and mechanisms

### 1137

#### Longitudinal trends in use and costs of prescription medication in patients with type 1 diabetes and kidney transplant

R. Lithovius<sup>1,2</sup>, V. Harjutsalo<sup>1,2</sup>, C. Forsblom<sup>1,2</sup>, M. Saraheimo<sup>1,2</sup>, P. Koskinen<sup>2</sup>, P.-H. Groop<sup>1</sup>, FinnDiane Study Group;

<sup>1</sup>Institute of Genetics, Folkhälsan Research Center, <sup>2</sup>Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland.

**Background and aims:** Kidney transplantation is a cost-effective treatment for ESRD in patients with type 1 diabetes. Over the past decades new and more expensive patented drugs, including new immunosuppressants, have reached the markets. However, studies on the recent trends in medication use and costs among patients with type 1 diabetes and kidney transplant are sparse and thus, necessary to elucidate. Therefore, we estimated trends in prescription medication use and costs in patients with type 1 diabetes after kidney transplantation.

**Materials and methods:** A total of 330 type 1 diabetes patients with kidney transplant were identified from The Finnish Diabetic Nephropathy Study. The data were linked to the Drug Prescription Register (purchases of drugs 1995 - 2009), the Hospital Discharge Register (until 2009) and the Drug Reimbursement Register (until 2009). Patients were divided into two groups according to kidney transplantation year: Group 1: 1986 - 2000 [ $n=179$ , mean follow-up 8.3 ( $\pm 1.6$ ) years] and Group 2: 2000 - 2009 [ $n=151$ , mean follow-up 6.7 ( $\pm 2.0$ ) years]. The follow-up was divided into nine 12 months periods after the first month of the transplantation. Costs were inflated to 2009 euro levels by using the Consumer Price Index. The generalized linear mixed models were used to evaluate the drug costs during the 9-year time period after transplantation. Costs were adjusted for age, sex, BMI, co-morbidities and transplantation year.

**Results:** The total costs decreased by 28% in both groups (in Group 1 from €11,360 to €8,900 and in Group 2 from €12,620 to €9,820) during follow-up ( $p<0.0001$ ). The average decrease in Group 1 between the first and the second year was 11.7%, while it was 1.7% by every 12 months thereafter, and was 7.0% and 2.7% in Group 2, respectively. Although the costs profiles were similar between the two groups ( $p=0.9$  for time\*group interaction), the cost level was higher in Group 2 than in Group 1 ( $p<0.0001$ ). The decreasing trend was observed for the immunosuppressive drugs ( $p<0.0001$ ) in both groups. However, the cost level of these drugs was significantly higher in Group 2 ( $p<0.0001$ ) than in Group 1. The cost of diabetes drugs decreased slightly at the beginning of the follow-up, but stabilised thereafter. Other medication (immunosuppressive and diabetes drugs excluded) costs were stable ( $p=0.3$ ) during the whole time period. The proportion of immunosuppressive drugs was more than 70% of the total costs, while diabetes drugs counted less than 10%. In Group 1 the most common immunosuppressive regimen was cyclosporine, azathioprine and corticosteroid combination, while cyclosporine, mycophenolate mofetil with or without corticosteroid was the most common combination in Group 2.

**Conclusion:** The total costs of prescription medication decreased over time in patients with type 1 diabetes and kidney transplant. Since no considerable differences were observed in the costs of diabetes or other drugs, the observed trend was mainly due to the decrease in the costs of immunosuppressants. This finding is in accordance with the clinical practice guidelines to reduce doses of immunosuppressants over time to minimize side-effects.

**Diabetes-related end stage renal disease in Austria 1965–2010 - analysis from the Austrian dialysis- and transplant registry**F.C. Prischl<sup>1</sup>, M. Auinger<sup>2</sup>, M.D. Säemann<sup>3</sup>, G. Mayer<sup>4</sup>, M. Wallner<sup>1</sup>, R. Kramar<sup>5</sup>;<sup>1</sup>Dept. Nephrology, Klinikum Wels-Grieskirchen, Wels, <sup>2</sup>3rd Dept. Internal Medicine, Krankenhaus der Stadt Wien-Hietzing, Vienna, <sup>3</sup>Dept. Nephrology and Dialysis, Medical University of Vienna, <sup>4</sup>Dept. Nephrology, Dialysis and Hypertension, Medical University of Innsbruck, <sup>5</sup>Austrian Dialysis and Transplant Registry, Wels, Austria.

**Background and aims:** As in other western countries diabetic kidney disease (DKD) is the leading cause of end-stage renal disease (ESRD) in Austria. There are marked differences in incidence and prevalence of DKD between countries even with comparable socio-economic status. We, therefore, analyzed ESRD due to DKD in Austria over 45 years and show that incident DKD-patients decrease since 2006.

**Materials and methods:** The Austrian Dialysis- and Transplant registry started in 1965 and yearly collects data on all patients with renal replacement therapy (RRT; including HD, PD, kidney alone and kidney combined with other organ transplantation). All patients with DKD-related ESRD (not diabetes as a comorbid condition) were analyzed longitudinally from 1965 until Dec 31<sup>st</sup>, 2010.

**Results:** Over 45 years, 7557 DKD-patients entered RRT programs in Austria (mean age at start: 63.1±12.6 years; 59.7% males; BMI 26.4±5.5 kg/m<sup>2</sup>). Mean RRT-duration amounted to 3.2±3.6 (median 2.0) years. Comorbid conditions reported any time were hypertension in 88.5%, cerebrovascular disease in 51.7%, coronary artery disease in 41.8%, peripheral atherosclerotic disease in 29.9%, and heart failure in 28.1% of patients. While DKD was not present in the ESRD-cohort in Austria until 1974, in 1975 seven incident type 1 diabetics and one type 2 diabetic started RRT (1.05 patients per million population - PMP). In the mid-eighties only, DKD increasingly necessitated RRT with a constant rise until 2006 (1985: 10.7 PMP; 1995: 33.6 PMP; 2005: 50.8 PMP; yearly growing rate 10%). After a peak of 436 incident DKD-ESRD patients in 2006, the numbers decreased continuously (2010: 350 patients, 41.7 PMP). This decrease in incident DKD-ESRD patients occurred despite a still growing diabetic population, estimated to amount to 390000 Austrians or 5.9 % of the population in 2007. Prevalence of all patients on RRT continuously increased from 755 PMP in 2001 to 995 PMP in 2010 and the same was true in patients with ESRD-DKD (2001: 100 PMP; 2010: 141 PMP). Mean age at RRT start was 35.0, 52.5, 62.4, 65.9 and 66.9 years in 1975, 1985, 1995, 2005 and 2010, respectively and on an average always was 3.1 years higher than in non-diabetics. According to the 2007 national survey on estimated diabetes prevalence, and compared to DKD patients commencing RRT the overall incidence rate PMP at risk was 135.2 compared to 1008.1 in diabetics with age-related marked differences. Finally, we calculated 5-year-survival probability in two DKD-cohorts, starting RRT in 1997-98 and in 2007-08. Survival was 28% in the period 1997-98 and 37.5% in the period 2007-08. Relative risk reduction unadjusted was 22% (HR 0.78, CI 95% 0.67-0.89; p=0.001).

**Conclusion:** Despite an increasing prevalence of diabetes in the Austrian population and in the RRT cohort, the incidence of DKD patients to enter RRT is decreasing since 2007 and 5-year survival probability is improving. It may be speculated that specific therapeutic maneuvers including antihypertensive therapy, especially ACE-inhibitors or ARBs, and multifactorial other therapeutic interventions may have resulted in this improvement.

## 1139

**Rate and determinants of association between retinopathy and nephropathy in patients with type 2 diabetes**G. Pugliese<sup>1</sup>, A. Solini<sup>2</sup>, G. Zoppini<sup>3</sup>, E. Orsi<sup>4</sup>, G. Zerbini<sup>5</sup>, R. Trevisan<sup>6</sup>, G. Gruden<sup>7</sup>, F. Cavalot<sup>7</sup>, L. Laviola<sup>8</sup>, S. Morano<sup>1</sup>, A. Nicolucci<sup>9</sup>, G. Penno<sup>2</sup>;<sup>1</sup>La Sapienza University, Rome, <sup>2</sup>University of Pisa, <sup>3</sup>University of Verona, <sup>4</sup>Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, <sup>5</sup>San Raffaele Scientific Institute, Milan, <sup>6</sup>Hospital of Bergamo, <sup>7</sup>University of Turin, <sup>8</sup>University of Bari, <sup>9</sup>Consorzio Mario Negri Sud, S. Maria Imbaro, Italy.

**Background and aims:** Few studies have investigated the association between diabetic retinopathy (DR) and nephropathy (DN) in type 2 diabetes. These studies examined small-sized samples and used only albuminuria or

proteinuria as markers of chronic kidney disease (CKD). This study was aimed at evaluating the rate and determinants of concordance between DR and CKD, as assessed by both albuminuria and estimated glomerular filtration rate (eGFR), in the large cohort of the Renal Insufficiency And Cardiovascular Events (RIACE) Italian Multicenter Study.

**Materials and methods:** Patients with type 2 diabetes (n=15,773), visiting consecutively 19 hospital-based Diabetes Clinics throughout Italy in years 2007–2008, were examined. DR was assessed by funduscopy in mydriasis and patients were classified as having no, non-advanced DR (mild or moderate non-proliferative) or advanced DR (pre-proliferative, proliferative or maculopathy). CKD was defined based on albuminuria, as assessed by immunonephelometry or immunoturbidimetry, and eGFR was calculated from serum creatinine using the simplified Modification of Diet in Renal Disease Study formula. Patients were classified as having no CKD or the CKD phenotype with albuminuria, reduced eGFR or both.

**Results:** The majority of subjects (51.87%) had neither DR nor CKD. Concordance between DR and CKD was found only in 11.50% of patients. Of them, 50.22% had non-advanced and 49.78% had advanced DR, whereas 48.62% had albuminuria alone, 21.66% had reduced eGFR alone and 29.72% had both, thus indicating that DR is more frequent in the albuminuric than in the non-albuminuric CKD phenotypes. Overall, DR was found in 30.70% of the 5,908 individuals with any CKD, whereas CKD was detected in 51.87% of subjects with any DR and in 58.64% of those with advanced DR. Discordance between DR and CKD was observed in 36.63% of subjects, with 10.67% having only DR (62.15% non-advanced and 37.85% advanced) and 25.96% having only CKD (50.49% albuminuria alone, 31.27% reduced eGFR alone and 18.25% both). Age, male gender, diabetes duration, HbA<sub>1c</sub>, hypertension, triglycerides, previous cardiovascular disease (CVD) and, inversely, HDL cholesterol were independently associated with presence of any CKD in individuals with advanced DR; correlates differed according to the presence of albuminuria and/or reduced eGFR. Conversely, factors correlating with presence of advanced DR in subjects with any CKD were diabetes treatment, previous CVD, albuminuria, and, inversely, smoking, eGFR and age at diagnosis.

**Conclusion:** Concordance of DR with CKD is low in subjects with type 2 diabetes, and CKD without DR is more frequent than isolated DR, at variance with type 1 diabetes. Factors independently associated with presence of any CKD in individuals with advanced DR differ, at least partly, from those correlating with presence of advanced DR in subjects with any CKD and also according to the CKD phenotype.

**Audit of avoiding over-referral to ophthalmology by monitoring early diabetic maculopathy within an inner city diabetes eye screening programme**

R.A. Cooper, G. Rayanagoudar, L.J. Bolter, P.N. Mitchell, J.V. Anderson; City, Hackney, Redbridge, Barking and Dagenham Diabetes Eye Screening Service, Homerton University Hospital, London, UK.

**Background and aims:** Photographic diabetic retinal screening relies on the analysis of two dimensional digital photographic images. These cannot detect the three dimensional abnormalities of macular oedema (M1). Image grading uses the presence of surrogate markers to infer the likely presence of macular oedema. These markers have high sensitivity but poor specificity. In the NHS Diabetic Eye Screening Programme this results in the referral of a large burden of patients into ophthalmology clinics, many of whom prove to need only observation. We defined a sub-category of M1 (M1a) and have audited the outcome of reviewing such cases 6-monthly within a diabetes eye screening service, rather than referring to ophthalmology.

**Materials and methods:** We defined M1a as: An image meeting the English National Grading criteria for M1, but with visual acuity (VA) of 6/6 or better (or 6/9 in the past with no deterioration when the new problem emerged) and with no new visual symptoms, unless the level of exudation is more than modest. Patients graded as M1a in one or both eyes between April 2008 and March 2009 were tracked through to their status at August 2011. Patients whose maculopathy worsened beyond the definition of M1a were referred to ophthalmology for assessment and treatment if necessary.

**Results:**

- 48 % of the 773 eyes either improved back to no maculopathy (M0) (30%) or remained stable at M1a (18%).
- 21% were referred not for worsening maculopathy in the index eye but for pre-proliferative (R2) or proliferative (R3) retinopathy in the eye with early

diabetic maculopathy (M1a) or referable retinopathy (R2, R3, M1) in the other eye.

- 7% of patients died, moved away or were lost to follow up
- Only 24% of the 773 eyes progressed to referable maculopathy during the follow up period of at least two and a half years.
- Of those referred for macular disease worse than M1a, only 1.81% of the cohort had a loss of 2 lines of vision or VA becoming worse than 6/12 at the point of referral.

Following referral for maculopathy worse than M1a, one third of patients have received focal macular laser photocoagulation in the follow up period. In one third of patients, the most recent VA was better than their VA at referral. In four fifths of eyes, VA had remained stable, dropped by fewer than two lines or had improved at recent follow up. More than four-fifths of eyes where the VA was better than 6/12 at referral were still above the driving threshold at recent follow up.

**Conclusion:** In whole population screening the monitoring of a pre-defined early stage of diabetic maculopathy within a diabetes eye screening service appears to offer a safe, convenient and low cost alternative reducing unnecessary referrals to ophthalmology.

## 1141

### Early detection of diabetic retinopathy by using digital fundus photography

M. Aguilar-Diosdado<sup>1</sup>, V. Regife<sup>2</sup>, E. Mayoral<sup>3</sup>, M. Cornejo<sup>3</sup>, S. Jimenez<sup>4</sup>, P. Alemany<sup>4</sup>, C. Lama<sup>2</sup>, L. Lahera<sup>2</sup>;

<sup>1</sup>Endocrinology & Nutrition Division, Puerta del Mar Hospital, Cadiz,

<sup>2</sup>Public Health Service of Andalusia, Sevilla, <sup>3</sup>Ophthalmology Division, Infanta Elena Hospital, Huelva, <sup>4</sup>Ophthalmology Division, Puerta del Mar Hospital, Cadiz, Spain.

**Background and aims:** Diabetic retinopathy (DR) is a principal cause of blindness in the developed countries and can be prevented by an early diagnosis and treatment. The aim of the study is to describe the results of the early detection of DR in the Andalusian Diabetic Retinopathy Early Detection Program (ADREDP).

**Materials and methods:** ADREDP is based in the DR screening by using digital fundus photography, performed at Primary Care centres and in Endocrinology offices. A first reading is performed by General Practitioners or Endocrinologists, who have been previously trained. In a second step, tests considered abnormal or doubtful are referred to the Ophthalmologist. As a false negative quality control, random and masked samples of tests considered as normal are referred for a second reading to an Ophthalmologist auditor.

**Results:** More than 2,000 care givers in 300 Primary Care centres and 36 hospitals have actively participated in this program. 215,000 subjects with diabetes have been included, and 254,200 tests have been finished: 82% were normal, 8% showed DR, 5% other findings and 5% were not valuations. Of 19,400 cases with DR, 94% were mild-moderate, 5% severe-very severe y 1% proliferative. 16.3% of the total tests were referred to the Ophthalmologist after the first reading because DR, and 2.3% because other pathological findings. In 3,500 tests considered as normal in the first study, the audit for the quality control found discrepancy in 10% (false negative).

**Conclusion:** The implementation of a global screening program of DR with digital fundus photography in a Public Health Service is useful, but an adequate planning and resources funding are needed. The high prevalence of mild and moderate grades of DR suggests it is a very suitable cost-benefit intervention.

### Distribution of diabetic retinopathy in the population attending the diabetic retinopathy screening service for Wales 2011-2012

A.F. Crowder<sup>1</sup>, G. Bhakta<sup>1</sup>, C.J. Richards<sup>1</sup>, R.L. Thomas<sup>2</sup>, S.D. Luzio<sup>2</sup>, R.A. Keigwin-Harris<sup>1</sup>, R. McPherson<sup>1</sup>, D.R. Owens<sup>2</sup>;

<sup>1</sup>Diabetic Retinopathy Screening Service for Wales, Rhondda Cynon Taf,

<sup>2</sup>Diabetes Research Group, Institute of Life Science, Swansea, UK.

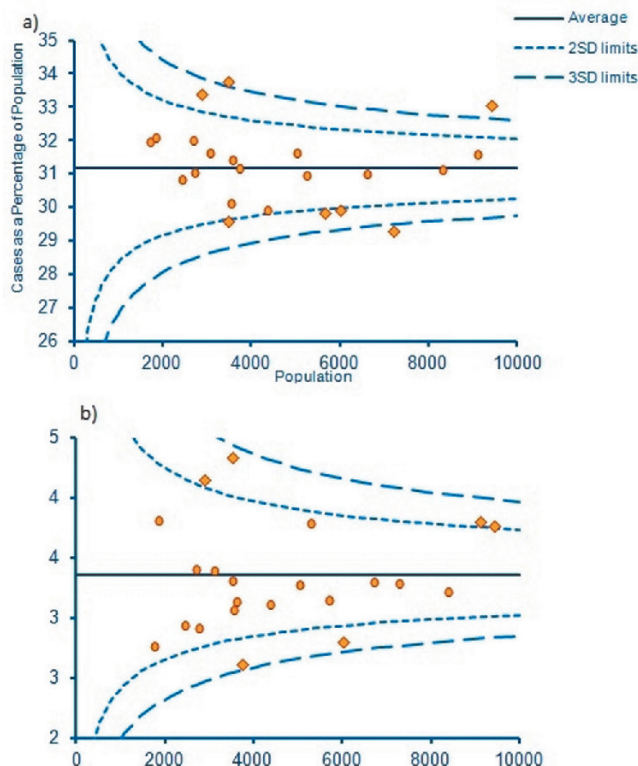

**Background and aims:** To determine the distribution of any diabetic retinopathy (DR) in the population attending for routine screening with the Diabetic Retinopathy Screening Service for Wales (DRSSW) during 2011.

**Materials and methods:** All eligible persons with diabetes (DM) in Wales over the age of 12 years attending a community based DR screening pro-

gramme between Jan 2011 and Jan 2012 were included in the analysis. Digital images were obtained using retinal photography (two 45° fields per eye) following mydriasis. Descriptive analysis were conducted utilising t-tests for continuous and chi-square for categorical variables.

**Results:** 102,427 persons (males 56.6%) with DM were screened of which 31,914 (31.1%) had DR. The percentage of any DR across the 22 localities is shown in Fig 1a. 15(68.1%) localities were within 2SD of the mean (31.2%  $\pm$ SD 1.2) (Group A), 4 (18.2%) had a lower (Group B) and 3 (13.6%) a higher (Group C) proportion of DR. Compared to A those in B and C were younger (66.5 vs 65.8 and 65.0 y, respectively  $p<0.001$ ). Compared to A those in B had fewer persons with T1DM (5.8 vs 5.4% ,  $p=0.02$ ), a higher proportion on diet (26.4 vs 28.5% ), and less on tablets (61.9 vs 60.4%) and insulin (11.7 vs 11.0%) ( $p<0.001$ ). Group C had more type 1 DM (6.3%,  $p=0.026$ ), fewer on diet (22.4%), and more on tablets (65.7%) and insulin (12.0%) ( $p<0.001$ ). The proportion of referable DR was within 2 SD's of the mean for 16 (72.7%) localities (Group X), with 2 (9.1%) having a lower (Group Y) and 4 (18.2%) a higher proportion (Group Z) (see Fig 1b). Compared to X those in Y and Z were younger (66.5 vs 65.9 and 65.1 y, respectively  $p<0.001$ ). Those in Y also had a lower proportion of T1DM (5.8 vs 5.3%  $p=0.047$ ). In comparison to X those in Z had a lower proportion on diet (27.4 vs 22.7%,  $p$  values), and a higher proportion on tablets (61.2 vs 65.2%) or insulin (10.6 vs 12.1%) ( $p<0.001$ ).

**Conclusion:** The majority of the 22 localities across Wales had similar proportions of any DR (15) and referable DR (16). Those with lower proportions had more persons with T2DM and on diet whilst those with higher proportions had more persons with T1DM and requiring insulin.

## 1143

### Associated factors for diabetic retinopathy in a Korean population: The 2008-2009 Korean national health and nutrition survey

D.-J. Kim, J. Yang, Y. Lee, J. Noh, J. Park, K. Ko, B. Rhee; Department of Internal Medicine, Inje University College of Medicine, Koyang, Republic of Korea.

**Background and aims:** We tried to evaluate the prevalence of and associated factors for diabetic retinopathy (DR) and investigate the optimal cutoff value of fasting plasma glucose (FPG) for DR in Korea.

**Materials and methods:** Among the 11,163 adults ( $\geq 19$  years old) from the fourth Korea National Health and Nutrition Examination Survey in 2008-2009, laboratory test, nutritional survey, and fundus examination data from

9,586 persons including 4144 men and 5472 women (age, 46 years [19–93]), were examined. For each participants, one 45 nonmydriatic digital retinal image centered on the fovea was taken per eye (2 images per person in total). DR was defined as the presence of 1 or more retinal microaneurysms or retinal blot hemorrhages with or without more severe lesions.

**Results:** Diabetes prevalence in this population was 8.6%. The prevalence of DR was 1.3% in whole population and that was 14.1% in persons with diabetes (3.9% in newly diagnosed diabetes, and 18.6% in previously diagnosed diabetes). In age- and sex-adjusted comparison, persons with DR were more obese and showed more frequency of hypertension, more frequency of diabetes, higher serum triglyceride, and lower serum HDL-cholesterol compared to those without DR. There was no difference of the presence of metabolic syndrome, self-reported cerebrovascular disease, or self-reported coronary heart disease according to the presence of DR. To evaluate associated factors for DR in whole population, logistic regression analysis for DR with age, sex, exercise, waist circumference, hypertension, serum HDL-cholesterol, serum triglyceride, anti-lipid drug, anti-diabetes medication, FPG, and diabetes duration as covariates was done. In this model, insulin treatment (vs. no anti-diabetes drug, OR [95% CI], 5.36 [1.93–14.90],  $p = 0.001$ ), FPG (1.01 [1.01–1.02],  $p < 0.001$ , per unit of FPG), and diabetes duration (1.07 [1.04–1.10],  $p < 0.001$ , per unit of diabetes duration) was associated with DR, respectively. Other parameters including age, sex, the presence of hypertension, and lipid profile were not significant. After including only persons with diabetes, insulin treatment, FPG, and diabetes duration was, also, associated with DR. To investigate the optimal cutoff value of FPG for DR, receiver operator curve analysis was done and 123.5 mg/dl of FPG was the optimal cutoff value (area under the curve = 0.876,  $p < 0.001$ ; sensitivity = 0.647, specificity = 0.970).

**Conclusion:** In this representative sample of Korean population, the prevalence of DR in persons with diabetes was about 14%, and the optimal cutoff value of FPG for DR was 123.5 mg/dl. The finding that only FPG and diabetes duration were associated with DR, suggested hyperglycemia could be the sole major determinant for DR and in the development of DR, other cardiovascular risk factors may be minor contributors.

## 1144

### Smoking as the potential link between Kimmelstiel-Wilson lesion and idiopathic nodular glomerulosclerosis: a single center retrospective study

R. Halmi, P. Degrell, I. Szejártó, G. Molnár, I. Wittmann;

2nd Department of Internal Medicine, University of Pécs, Medical Faculty, Hungary.

**Background and aims:** Nodular sclerosis is hallmark of both Kimmelstiel-Wilson lesion (KW) and idiopathic nodular glomerulosclerosis (ING). Chronic smoking is considered only as a risk factor of KW but as one potential cause of ING. The prevalence of smokers among patients with Kimmelstiel-Wilson lesion is unknown.

**Materials and methods:** In a retrospective analysis, native renal biopsy specimens ( $n=1128$ , 2001–2011) were evaluated, male patients' characteristics and smoking habits were assessed in three groups: diabetic patients either with KW ( $n=15$ ), or other classes of diabetic nephropathy (DNP;  $n=46$ ); and patients with ING ( $n=7$ ).

**Results:** Majority of the KW group (13/15= 87%) were smokers, unlike the DNP group (16/46= 35%;  $p=0.001$  vs. KW) but similar to the ING group (7/7= 100%;  $p=1.000$  vs. KW). However, the other known factors responsible for either the worsening of DNP or the development of ING did not differ in the groups (KW/DNP/ING; age, 56+/-1/ 56+/-9/ 55+/-1 ys;  $p=0.935$ ; body mass index, 30+/-5/ 31+/-5/ 28+/-6 kg/m<sup>2</sup>;  $p=0.538$ ; duration of diabetes mellitus, 11+/-6/10+/-7/0 ys;  $p=0.617$ ; glycaemic control (HbA<sub>1c</sub>, 6.5+/-1/6+/-1/- %;  $p=0.88$ ; prevalence of hypertension, 93/87/86 %;  $p=0.782$ ; and duration of hypertension, 11+/-8/ 13+/-10/ 11+/-6 ys;  $p=0.948$ ; serum total cholesterol, 6+/-4/ 6+/-2/ 7+/-2 mmol/l;  $p=0.500$ ; triglyceride, 3+/-3/ 3+/-3/ 3+/-1 mmol/l;  $p=0.784$ ; eGFR, 34+/-22/ 46+/-32/ 46+/-28ml/min;  $p=0.483$ ; and RAS-blocker treatment 100/ 87/100%;  $p=0.222$ ).

**Conclusion:** We propose that chronic cigarette smoking could contribute to the development of Kimmelstiel-Wilson lesions.

## PS 099 Predicting nephropathy

### 1145

#### The pulsatility index and the resistive index in peripheral arteries are associated with albuminuria excretion in type 2 diabetes

B. Yang, Z. Sun, H. Yin, S. Li, H. Jin, S. Wang, S. Qiu;

Diabetes Institute of Southeast University, Nanjing, China.

**Background and aims:** Diabetic nephropathy and peripheral arterial disease are common vascular complications among subjects with type 2 diabetes. The pulsatility index and the resistive index in renal arteries have been found to correlate with the severity of the renal disease. The objective of the present study was to investigate the potential relationship between these indices and the albuminuria excretion which may become effective markers for evaluating the association between peripheral artery disease and diabetic nephropathy in type 2 diabetes.

**Materials and methods:** The total number of 996 type 2 diabetes (522 females, 474 males, mean age 59 years) was enrolled in the study, excluding individuals with history of angiocardiopathy, cerebrovascular disease, end-stage renal disease, malignancy, amputation and overt calcification of the lower limbs (ankle brachial index > 1.3). Ankle brachial index was measured and calculated with Doppler ultrasound. The pulsatility index and resistive index were figured from the blood flow velocities by the measuring software. The maximum value of ankle brachial index and the average values of pulsatility index and resistive index of two legs were collected and analyzed individually. Parameter of urinary albumin excretion was evaluated from the albumin-to-creatinine ratio in a random spot sample, which at least 2 of 3 samples collected within 3- to 6-month time frame were used to decide the degree of albuminuria.

**Results:** In a multiple regression analysis, after adjustment with confounding factors such as age, sex, body mass index, heart rate, blood pressure, plasma glucose, plasma lipids and HbA<sub>1c</sub>, albumin-to-creatinine ratio correlated more significantly to the pulsatility index ( $r = 0.43$ ,  $P = 0.02$ ) and resistive index ( $r = 0.56$ ,  $P = 0.01$ ) than to the ankle brachial index ( $r = 0.12$ ,  $P = 0.04$ ). Furthermore, when dividing the patients into two groups by the median resistive index value, there was a magnificent distinction of albumin-to-creatinine ratio between the groups ( $P = 0.01$ ). For pulsatility index this difference was also present ( $P = 0.03$ ).

**Conclusion:** Pulsatility index and resistive index associated with the diabetic nephropathy, as reflected by the albumin-to-creatinine ratio during the early complication of diabetes. Pulsatility index and resistive index may be more suitable markers for evaluating the relationship between peripheral artery disease and diabetic nephropathy in type 2 diabetes.

### 1146

#### Bone mineral density, kidney function and arterial stiffness in long-standing type 1 diabetic patients with or without diabetic nephropathy

M. Lajer<sup>1</sup>, S. Theilade<sup>1</sup>, C. Joergensen<sup>1</sup>, F. Persson<sup>1</sup>, G. Andr sd ttir<sup>1</sup>, S.

Nielsen<sup>1</sup>, H. Reinhard<sup>1</sup>, H.-H. Parving<sup>2</sup>, L. Tarnow<sup>1</sup>, P. Lacy<sup>3</sup>, B. Williams<sup>3</sup>,

P. Rossing<sup>1</sup>;

<sup>1</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>2</sup>Dep. of medical endocrinology, Rigshospitalet, Copenhagen, Denmark, <sup>3</sup>Dep. of Cardiovascular Sciences, Univ. of Leicester, UK.

**Background and aims:** Patients with chronic kidney disease including diabetic nephropathy have been suggested to have a lower bone mineral density (BMD). The aim of the study was to evaluate bone mineral density (BMD) and arterial stiffness among long-standing type 1 diabetic patients with or without overt diabetic nephropathy.

**Materials and methods:** Cross sectional evaluation of a prospectively followed cohort 141 patients with diabetic nephropathy (DN) (55% men; age [mean±SD] 53±9 years, 42±8 years of diabetes, duration of DN 22±6 years) and 230 with persistent normoalbuminuria (50% men, 58±10 years, 40±10 years of diabetes). Femoral and lumbar spine BMD (g/cm<sup>2</sup>) was measured by dual energy x-ray absorptiometry (DXA). Osteopenia and osteoporosis were defined by any T-score from -2.5 to -1.0 and <-2.5, respectively. Glomerular filtration rate (GFR) by <sup>51</sup>Cr-EDTA was determined in DN and estimated GFR (eGFR, MDRD formula) in normoalbuminuric patients. Pulse wave velocity (PWV) was measured by SphygmoCor and 24h pulse pressure (PP) by BPro watch.

**Results:** Among patients with DN, 73 (52%) and 36 (26%) had osteopenia or osteoporosis, respectively compared to 124 (54%) and 32 (14%) of normoal-

buminuric patients ( $p=0.013$ ). 34% of males with DN vs. 14% with normoalbuminuria had osteoporosis ( $p<0.001$ ) and lower age-sex matched Z-scores ( $p<0.001$ ). Among women, only femoral Z-scores were different. Baseline eGFR levels did not change with declining BMD. Among patients with DN, 24h brachial and central PP were elevated ( $p=0.007$  and  $0.014$ , respectively) while 24h brachial and central systolic dip were lower in osteoporosis patients compared to osteopenia and normal BMD ( $p<0.001$ ). PWV also tended to be elevated and GFR lower in osteoporosis patients although not significantly ( $p=0.12$  and  $0.14$ ). Among normoalbuminuric patients, both 24h brachial and central BP and PWV were elevated in osteoporosis patients ( $p=0.004$ ,  $0.005$  and  $0.028$ , respectively) while 24h brachial and central systolic dip were not significantly different.

**Conclusion:** The risk of osteoporosis was highest among male type 1 diabetes patients and long-standing DN and femoral BMD was associated with albuminuria status, pulse pressure and dipping. Hence, screening and treatment of osteoporosis in patients with albuminuria or arterial stiffness should be considered.

## 1147

### Impaired relaxation of arterial wall during a rest in supine position may be a risk factor of arteriosclerosis and it is frequent in diabetic patients

H. Sasaki<sup>1</sup>, S. Kurisu<sup>1</sup>, J. Ibatani<sup>1</sup>, M. Nakatani<sup>1</sup>, K. Ogawa<sup>1</sup>, H. Yamasaki<sup>1</sup>, H. Wakasaka<sup>1</sup>, H. Furuta<sup>1</sup>, M. Nishi<sup>1</sup>, T. Akamizu<sup>1</sup>, K. Nanjo<sup>2</sup>

<sup>1</sup>First Department of Medicine, Wakayama University of Medical Science,

<sup>2</sup>Wakayama Rosai Hospital, Japan.

**Background and aims:** Although hyperactivity of adrenergic function has been supposed to promote arteriosclerosis, simple clinical methods to assess early adrenergic dysfunction did not exist. Cardio-ankle vascular stiffness index (CAVI) is a newly established method for estimating arterial wall stiffness which reflects both of elastic and muscular arteries. CAVI has been reported to decrease by the administration of alpha-blockade. Therefore, CAVI may reflect the change of vascular stiffness mediated by alpha-adrenergic vasomotor function. Our aim was to examine whether the change of CAVI during a resting reflects adrenergic function or not, and another aim was to elucidate the association between the change of CAVI and arteriosclerotic markers in non-diabetic (NDM) and diabetic (DM) subjects.

**Materials and methods:** *1st study:* We measured CAVI twice just at coming the laboratory and after 20 minutes' rest in supine position in 82 NDM and 40 DM subjects. The changes of CAVI (d-CAVI) were calculated and compared between NDM and DM subjects. The relationship between d-CAVI and the intima-media thickness of carotid artery (IMT) measured by ultrasound sonography was investigated in 38 NDM and 22 DM subjects. The clinical risk factors associated to IMT were evaluated by the multiple regression analysis using IMT as a dependent variable, gender, BMI, systolic blood pressure, HbA1c, d-CAVI as independent variables. *2nd study:* We assessed the change of adrenergic vasomotor tone during cold stimulation by continuous monitoring of photoplethysmogram wave at contralateral index finger and big toe in 49 NDM subjects. Cold stimulation was performed by the immersion of left hand into ice-water for 10 seconds. The subjects were divided into two groups according to the vasoconstriction response, good response (GR) group and poor response (PR) group. CAVI was also measured twice before and after the cold stimulation, and the changes of CAVI were compared between GR and PR groups.

**Results:** *1st study:* Though CAVI of NDM subjects decreased significantly by rest in supine position ( $6.69 \rightarrow 6.42$ ,  $p<0.001$ ), CAVI of DM patients did not significantly change ( $8.50 \rightarrow 8.32$ ,  $p=0.143$ ). Prevalence of the subjects whose CAVI were not decreased bilaterally in DM patients was significantly higher than that in NDM subjects ( $63\%$  vs  $43\%$ ,  $p=0.039$ ). D-CAVI was significantly correlated with IMT in NDM ( $r=0.374$ ,  $p=0.020$ ), but not in DM subjects. When NDM subjects were divided into 3 groups by d-CAVI equally, the IMT of smaller tertile was significantly thicker than that of larger tertile ( $0.61$  mm vs  $0.45$  mm,  $p=0.009$ ). Multiple regression analysis revealed that significant risk factors for thicker IMT were BMI and d-CAVI in NDM subjects. *2nd study:* GR and PR groups consisted of 24 and 25 subjects, respectively. Though CAVI increased by cold stimulation significantly in GR group ( $6.08 \rightarrow 6.35$ ,  $p=0.012$ ), CAVI did not significantly changed in PR group ( $6.58 \rightarrow 6.77$ ,  $p=0.077$ ).

**Conclusion:** Our data suggest that arterial wall relaxation by resting could be evaluated by serial CAVI measurement, and that arterial wall relaxation might reflect adrenergic vasomotor function, and that impaired relaxation is more frequent in DM than NDM subjects and it is significantly associated with arteriosclerosis.

## 1148

### Cerebral perfusion reserve and endothelial function in patients with type 1 diabetes mellitus

E. Kosobyan<sup>1</sup>, I. Jarek-Martynowa<sup>1</sup>, M. Martinov<sup>2</sup>, M. Shestakova<sup>1</sup>;

<sup>1</sup>Endocrinology Research Center, <sup>2</sup>Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation.

**Background and aims:** To examine cerebral perfusion reserve (CPR) and endothelial function in patients with a type 1 diabetes mellitus (T1DM) and microangiopathy.

**Materials and methods:** We examined 130 patients with T1DM (66 women and 64 men), age from 18 to 40 years (mean age  $28.3 \pm 4.6$  years), mean duration of T1DM  $17.1 \pm 6.1$  years. The control group (CG) included 26 healthy persons matched by gender and age. 72 (55.4%) patients had diabetic nephropathy (DN): Chronic Kidney Disease stage 1 (CKD1) - 25 (19.2%), Chronic Kidney Disease stage 2 (CKD2) - 22 (16.9%), Chronic Kidney Disease stage 3 (CKD3) - 25 (19.2%). Diabetic retinopathy (DR) was diagnosed in 110 persons: nonproliferative retinopathy (NPR) - 47 (36.6%), preproliferative retinopathy (PPR) - 22 (16.9%), proliferative retinopathy (PR) - 41 (31.5%). Groups of patients with T1DM were comparable on level of HbA1c. Parameters of blood flow velocity in the middle cerebral artery (MCA) were assessed by Transcranial Doppler ("Bioss", Russia). To determine the CPR we used carotid compression test. Arterial stiffness index (SI) and endothelial function was assessed by peripheral arterial tonometry technique ("Angioscan", Russia).

**Results:** Indicators of CPR in patients with CKD0 ( $12.9 \pm 13.0\%$ ) did not differ significantly from the CG ( $23.0 \pm 7.2\%$ ,  $p=0.06$ ). CPR was reduced in comparison with DR0 ( $9.2 \pm 6.1\%$ ,  $p=0.019$ ). There was a reduction of CPR in patients with DN ( $6.0 \pm 7.7\%$ ,  $p<0.001$ ) compared with CG; and reduction of CPR in patients with DR ( $9.2 \pm 11.6\%$ ,  $p=0.019$ ) compared with CG. In patients with no signs of DR we observed an increase in peak systolic blood flow velocity in the MCA ( $95.5 \pm 10.3$  m/s) compared with the CG ( $72.0 \pm 10.4$  m/s,  $p=0.047$ ). SI were significantly higher in the group of patients with diabetes ( $9.5 \pm 2.6$  m/s) in comparison to CG ( $8.3 \pm 1.3$  m/s,  $p=0.028$ ). When comparing SI between patients with T1DM without microvascular complications and CG we observed no statistically significant difference. SI was higher in patients with NPR ( $9.5 \pm 1.8$  m/s,  $p=0.02$ ), PPR ( $9.8 \pm 2.6$  m/s,  $p=0.041$ ), PR ( $10.4 \pm 2.0$  m/s,  $p<0.001$ ) compared with healthy subjects ( $8.3 \pm 1.3$  m/s) and CKD1 ( $9.7 \pm 2.1$  m/s,  $p<0.001$ ), CKD2 ( $11.2 \pm 2.8$  m/s,  $p=0.034$ ), CKD3 ( $9.8 \pm 1.8$  m/s,  $p<0.001$ ). During reactive hyperemia test: increase in the amplitude of signal prevailed over decline in the progression of DR ( $r=0.86$ ,  $p=0.003$ ), DN ( $r=0.99$ ,  $p=0.001$ ).

**Conclusion:** The index SI may be an early marker of macrovascular diseases in patients with microvascular complications. There is a decrease of the autoregulatory capacity of cerebral arteries in patients with T1DM, which increases with the development of microvascular complications. Increased peak systolic blood flow velocity in the MCA in the absence of DR may be a sign of the beginning of formation of changes in the retina.

## 1149

### Clinical evaluation of analytical variations in serum creatinine measurements: why laboratories should abandon Jaffé techniques

I. Drion<sup>1</sup>, N. Kleefstra<sup>1</sup>, K.H. Groenier<sup>1</sup>, C. Cobbaert<sup>2</sup>, C. Weykamp<sup>3</sup>, J.F.M. Wetzels<sup>4</sup>, H.J.G. Bilo<sup>1</sup>;

<sup>1</sup>Diabetes Centre, Zwolle, <sup>2</sup>Clinical Chemistry, Leiden University Medical Center, Zwolle, <sup>3</sup>European Reference Laboratory, Streekliekenhuis Koningin Beatrix, Winterswijk, <sup>4</sup>Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

**Background and aims:** Serum creatinine (SCr) based prediction equations are frequently used in screening and clinical settings in order to assess the glomerular filtration rate (GFR). Moreover, chronic kidney disease (CKD) staging directly relies on these estimated GFR values. Using accurate SCr measurements is essential, since systematic errors cause unreliable renal function estimates, leading to incorrect drug dose adjustments, misclassifications in CKD staging and incomparability of patient data [1-4]. Non-equivalence in serum creatinine (SCr) measurements across Dutch laboratories and the consequences hereof on chronic kidney disease (CKD) staging were examined.

**Materials and methods:** National data from the Dutch annual external quality organization of 2009 were used. 144 participating laboratories examined 11 pairs of commutable, value-assigned (by the Joint Committee on Traceability in Laboratory Medicine) SCr specimens in the range  $52\text{--}262$   $\mu\text{mol/L}$ .

using Jaffé or enzymatic techniques. Regression equations were created for each participating laboratory (by regressing values as measured by participating laboratories on the target values of the samples sent by the external quality organization); area under the curves were examined and used to rank laboratories. The 10<sup>th</sup> and 90<sup>th</sup> percentile regression equation were selected for each technique separately. To evaluate the impact of the variability in SCr measurements and its eventual clinical consequences in a real patient population, we used a cohort of 82424 patients. The SCr measurements of these 82424 patients were introduced in the 10<sup>th</sup> and 90<sup>th</sup> percentile regression equations. The newly calculated SCr values were used to calculate an estimated glomerular filtration rate (eGFR) using the 4-variable Isotope Dilution Mass Spectrometry traceable Modification of Diet in Renal Disease formula. Differences in CKD staging were examined, comparing the stratification outcomes for Jaffé and enzymatic SCr techniques.

**Results:** Jaffé techniques overestimated SCr: 21%, 12%, 10% for SCr target values 52, 73 and 94  $\mu\text{mol/L}$ , respectively. For enzymatic assay these values were 0%, -1%, -2%, respectively. eGFR using the MDRD formula and SCr measured by Jaffé techniques, staged patients in a lower CKD category. Downgrading to a lower CKD stage occurred in 1-42%, 2-37% and 12-78.9% of patients for the 10<sup>th</sup> and 90<sup>th</sup> percentile laboratories respectively in CKD categories 45-60, 60-90 and >90 mL/min/1.73m<sup>2</sup>. Using enzymatic techniques, downgrading occurred only in 2-4% of patients.

**Conclusion:** Enzymatic techniques lead to less variability in SCr measurements than Jaffé techniques, and therefore result in more accurate staging of CKD. Therefore the specific enzymatic techniques are preferably used in clinical practice in order to generate more reliable GFR estimates.

## 1150

### The performance of MDRD and CKD-EPI equations in diabetic patients with various degrees of albuminuria

M. Vucic Lovrencic<sup>1</sup>, V. Radisic Biljak<sup>1</sup>, M. Prasek<sup>2</sup>, P. Pavkovic<sup>3</sup>, M. Knotek<sup>3</sup>;

<sup>1</sup>Institute of Clinical Chemistry and Laboratory Medicine, Merkur Teaching Hospital, <sup>2</sup>Vuk Vrhovac University Clinic, Merkur Teaching Hospital,

<sup>3</sup>Institute of Nephrology, Merkur Teaching Hospital, Zagreb, Croatia.

**Background and aims:** Early changes in diabetic nephropathy involve increased urinary albumin excretion rate (AER) and/or a temporal increase in glomerular filtration rate (GFR, hyperfiltration), which are not necessarily inter-related. Both albuminuric and non-albuminuric pathways to renal impairment have been identified in diabetes, emphasizing the importance of monitoring appropriate markers when screening for diabetic nephropathy. The aim of this study was to compare the performance of Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) and Modification of Diet in Renal Disease Study (MDRD) equation in estimating GFR in a cohort of diabetic patients with various degrees of albuminuria.

**Materials and methods:** In a group of 842 diabetic patients GFR was estimated from standardized creatinine, with MDRD-Study and CKD-EPI equations, and their performance evaluated regarding clinical stages categories of albuminuria and chronic kidney disease (CKD).

**Results:** A total of 842 adult diabetic patients (48,2% males, 82% type 2 diabetes) were included in this study. Females were younger (median age: 55 vs 58,  $P=0.013$ ), had lower serum creatinine ( $65\pm14$  vs  $80\pm18$   $\mu\text{mol/L}$ ,  $P<0.001$ ), but no gender-associated differences in eGFR, calculated by either equation, HbA<sub>1c</sub> and albuminuria were found. Patients with normoalbuminuria ( $n=364$ ) had higher eGFR when calculated by CKD-EPI, than MDRD-Study equation [median (IQR): 103 (91-115) vs 97 (85-113) mL/min/1.73 m<sup>2</sup>,  $p=0.006$ ,  $n=364$ ], which significantly influenced the prevalence of stage 1 CKD [eGFR>90 mL/min/1.73 m<sup>2</sup>: 76,7% (CKD-EPI) vs. 65,1% (MDRD-Study),  $P=0.005$ ]. There were no differences between the eGFR values derived by two equations in patients with micro- and macroalbuminuria ( $n=290$  and 198, respectively), and more advanced staging of CKD.

**Conclusion:** CKD-EPI equation might be a superior surrogate marker of GFR in patients with normoalbuminuria and hyperfiltration and could be used as a screening tool for early renal impairment in diabetes. Its validity as a marker of progression of diabetic nephropathy remains to be established.

## 1151

### The effects of RAAS blockade on CIAKI (contrast induced acute kidney insufficiency) in patients with type 2 diabetes and in non-diabetic patients

E. Lee<sup>1</sup>, M. Kim<sup>1</sup>, N. Han<sup>1</sup>, S. Kim<sup>1</sup>, T. Kim<sup>1</sup>, T. Kim<sup>1</sup>, M. Kwon<sup>1</sup>, S. Lee<sup>1</sup>, M. Park<sup>2</sup>, B. Rhee<sup>1</sup>, J. Park<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, College of Medicine, Inje University,

<sup>2</sup>Department of Internal Medicine, College of Medicine, Dong-A University, Busan, Republic of Korea.

**Background and aims:** An ACE inhibitor or ARB is a drug used primarily for the treatment of hypertension in patients with diabetes mellitus because of effect of proteinuria reduction. CIAKI (contrast induced acute kidney insufficiency) is defined as an increase in serum creatinine within 72 hours after the contrast administration in the procedure using of contrast medium, such as coronary angiography. RAAS blockade may blunt autoregulation of kidney and precipitate prerenal ARF in patients with volume depletion. The CIAKI is also caused by a similar mechanism. But, there are few study about their relationship. The purpose of this study was to compare the influence of ACE inhibitors or ARBs on CIAKI in patients with type 2 diabetes and in non-diabetic patients.

**Materials and methods:** A total of 1472 patients who undergoing coronary angiography was divided into four groups according to hystory of diabetes and previous use of ACE inhibitor or ARB, then the incidence of CIAKI in each group were compared. CIAKI was defined as an increase in serum creatinine of  $\geq 25\%$  or  $\leq 0.5\text{mg/dl}$  above the baseline value within 72 hours after the contrast administration. In the analysis, patient outcoms were adjusted for age, sex, before creatinine, smoking status, dye volume, haemoglobin and eGFR and compared using propensity score-matched analysis.

**Results:** RAAS blockade(+) group showed higher incidence of CIAKI compared to RAAS blockade (-) group, but there were other compounding factors. To overcome limitations, we performed analysis after matching groups using propensity score. Among non-diabetic patients, the incidence of CIAKI was 22.9% in the RAAS blockade (+) group and 14.0% in RAAS blockade (-) group. The odds ratio for development of CIN with respect to RAAS blockade was 1.821( $P=0.018$ , 95% CI, 1.104-3.005). In diabetic patient group, the incidence of CIAKI was 16.0% in the RAAS blockade (+) group and 13.6% in RAAS blockade (-) group. The odds ratio for development of CIN with respect to RAAS blockade was 1.217( $P=0.532$ , 95% CI, 0.658-2.250). They showed same direction and tendency under sensitivity analysis.

**Conclusion:** Although use of ACE inhibitor or ARB may be an independent risk factor for developing CIAKI in non-diabetic patients, no harmful effect was found in diabetic patients.

## 1152

### Prevention of contrast-induced nephropathy in diabetic patients with renal function impairment: sodium bicarbonate versus sodium chloride-based hydration

P. Boucek, T. Havrdova, O. Oliyarnyk, J. Skibova, V. Pecenkova, D. Sarkady; Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

**Background and aims:** Contrast-induced nephropathy (CIN) is defined as renal function impairment following intravascular contrast medium use and hypothesized i.a. to be mediated by oxidative stress in the acid environment of the renal medulla. Sodium bicarbonate ( $\text{NaHCO}_3$ ) hydration has been used as preventive measure in studies of CIN, but its positive protective effects remain controversial. Moreover, the utility of  $\text{NaHCO}_3$  in patients with diabetes (DM) and kidney disease, a population at major risk of CIN, has not been addressed specifically, but merely as subgroup analysis.

**Materials and methods:** We present data from a prospective, randomized, double blind, sodium chloride (NaCl) hydration-controlled study of  $\text{NaHCO}_3$  which included 120 DM patients with impaired renal function (screening creatinine  $\geq 100$   $\mu\text{mol/L}$  (1.1 mg/dL)) undergoing an elective radiologic procedure with contrast medium use. Patients were randomized to receive a  $\text{NaHCO}_3$  ( $n=61$ ) or NaCl ( $n=59$ ) in dextrose infusion (154 mmol/L; 3 mL/kg/hour for 1 hour before and 1 mL/kg/hour for 6 hours after procedure). The primary end-point - incidence of CIN - was defined as creatinine increase of  $\geq 25\%$  and/or  $\geq 44$   $\mu\text{mol/L}$  (0.5 mg/dL) within 2 days following administration of contrast. Secondary end-points were maximal changes in creatinine, eGFR (MDRD formula) and spot urine 8-isoprostane levels (8-IPF<sub>2a</sub>/creatinine ratio) as measure of oxidative stress.

**Results:** Apart from marginally lower age of the  $\text{NaHCO}_3$ -treated patients (mean (SD); 63 (11) vs. 67 (10) yrs;  $p=0.49$ ), the groups were comparable with

regard to sex, BMI, HbA<sub>1c</sub>, baseline creatinine, eGFR, glycaemia and contrast dose given. CIN occurred in 7 (11.5 %) and 5 (8.5 %) patients of the NaHCO<sub>3</sub> and NaCl groups, resp. ( $p=0.76$ ; Fisher's exact test). No significant difference was seen in any of the secondary outcome measures. (Table).

Group	creatinine ( $\mu\text{mol/L}$ )	$\Delta$ creatinine ( $\mu\text{mol/L}$ )	eGFR ( $\text{mL/s}$ )	$\Delta$ eGFR ( $\text{mL/s}$ )	8-iPF <sub>2a</sub> / creatinine ( $\text{pg/mg}$ )	$\Delta$ 8-iPF <sub>2a</sub> / creatinine ( $\text{pg/mg}$ ) <sup>*</sup>
NaHCO <sub>3</sub>	170 (84)	14 (31)	0.69 (0.3)	-0.06 (0.08)	937 (506)	36 (525)
NaCl	160 (74)	9 (26)	0.70 (0.27)	-0.05 (0.08)	1081 (661)	19 (749)
P	0.49	0.33	0.84	0.45	0.20	0.89

Comparison of baseline values and maximal changes ( $\Delta$ ) within 2 days post contrast (two-sample t-test)

Means (SD); <sup>\*</sup>Full data available in 53 patients in each group

**Conclusion:** Though limited by its single-centre design, the results of the study suggest that sodium bicarbonate does not provide additional protection against contrast-induced nephropathy in DM patients with impaired renal function in comparison with standard sodium chloride-based hydration. *Clinical Trial Registration Number: EudraCT: 2007-007546-36*  
*Supported by: Grant MZO 00023001 of the Czech Ministry of Health*

### Analysis on the prevalence and risk factors of abnormal fasting glucose after renal transplantation

M. Yu<sup>1</sup>, M. Chen<sup>1,2</sup>, M. Xu<sup>3</sup>, J. Gao<sup>4</sup>, X. Gao<sup>1</sup>;

<sup>1</sup>Endocrinology, Zhongshan hospital affiliated to Fudan University, Shanghai, <sup>2</sup>Endocrinology, Fujian Provincial people's Hospital, Fujian, <sup>3</sup>Urology, Zhongshan hospital affiliated to Fudan University, Shanghai, <sup>4</sup>Evidence-Based Medicine Center, Zhongshan hospital affiliated to Fudan University, Shanghai, China.

**Background and aims:** To explore the abnormal rate of PTDM diagnosed based on FPG and its associated risk factors in patients surviving for more than 1 year after renal transplantation.

**Materials and methods:** For 428 non-diabetic patients before transplantation receiving kidney transplant between 1 January, 1993 and 31 December, 2008, we analyzed the prevalence and associated risk factors of PTDM after transplantation according to FPG.

**Results:** Of the 428 Patients, 87 developed PTDM (20.3%) within a mean follow-up of (5.65 $\pm$ 3.68) years. The onset of PTDM occurred in 57 patients (in 65.5% of total PTDM) primarily within the first year after transplantation. There was no difference in the incidence of PTDM among three transplantation ages. Univariate analysis identified variables to be associated with the onset of PTDM: older age, a higher BMI, smoking history, positive family history of diabetes mellitus, deceased donor transplantation, hepatitis C virus infection, cytomegalovirus infection, FPG pre-transplantation as well as 1 week after transplantation, TC and TG pre-transplantation, a switch from CSA to FK506-based immunosuppressive regimen, peak plasma concentration of CSA in the first 6 and 12 months. The prevalence of PTDM were markedly elevated ( $P<0.05$ ) in the group who were converted to FK506 but not in the group who were converted to RAM. By multivariate analysis, five factors were independently associated with the onset of PTDM: FPG pre-transplantation (OR=1.48,  $P=0.036$ ), older recipient age (OR=1.10,  $P=0.044$ ), BMI (OR=1.18,  $P=0.035$ ).

**Conclusion:** The incidence of PTDM diagnosed based on FPG was 20.3% in patients surviving for more than 1 year after renal transplantation, and the onset of PTDM occurred primarily (65.5% of total PTDM) within the first year after transplantation. Main independent risk factors of PTDM included higher FPG levels, older recipient age, BMI, hepatitis C virus infection, deceased donor transplantation.

## PS 100 Small fibres in neuropathy: clinical

### 1154

#### SUDOSCAN: a rapid, objective and non-invasive method of diagnosing diabetic autonomic neuropathy

S. Tesfaye, J. Daives, A. Sankar, T. Cash, E. Cachia, G. Rao, D. Selvarajah; Diabetes Research Unit, University of Sheffield, UK.

**Background and aims:** Diabetic cardiac autonomic neuropathy (CAN) is a serious complication of diabetes and carries up to a five-fold increased risk of mortality. Current methods of detecting CAN are based on a battery of cardiovascular reflex tests (CARTs) that are too cumbersome and impractical for widespread use in busy clinical practice. SUDOSCAN is a new and rapid method of assessing sudomotor function by measuring electrochemical skin conductance (ESC) through reverse iontophoresis. The aim of the present study was to evaluate if SUDOSCAN can reliably diagnose CAN.

**Materials and methods:** Healthy, non-diabetic volunteers (HV,  $n=13$ ) 41 and subjects with type 1 diabetes ( $n=41$ ) and 13 healthy volunteers (HV) underwent detailed assessments including clinical, neurophysiological (Neuropathy Impairment Score of the Lower Limbs NISLL+7 tests of nerve function [NISLL+7]) and 5 CARTs (O'Brien protocol). Based on CARTs subjects were divided into CAN [3 abnormal CART results], Subclinical CAN [1-2 abnormal results] and No-CAN [0 abnormal results]. All subjects underwent the SUDOSCAN test. Participants placed their hands and feet on electrodes, and an incremental low direct current ( $<4\text{V}$ ) was applied to the anode for 2min. ESC ( $\mu\text{Siemens}$ ) as a measure of sudomotor function was obtained from the voltage and current and an autonomic risk score was calculated.

**Results:** The results presented in the table below show that SUDOSCAN can detect established CAN having corrected for age and BMI.

**Conclusion:** SUDOSCAN a simple, rapid ( $<5\text{min}$ ) and objective method of screening that doesn't require special patient preparation or medical personnel training may serve as screening test for CAN. It could help adhere to ADA's recommendation of annual AFT for all diabetic patients which is currently not fulfilled as current tests are cumbersome and time consuming.

#### Determination of diabetic peripheral neuropathy prevalence and associated risk factors in Chinese diabetic and pre-diabetic subjects

B. Lu, J. Hu, J. Wen, Y. Li;

Department of Endocrinology, Huashan Hospital, Institute of Endocrinology and Diabetology at Fudan University, Shanghai, China.

**Objective:** Diabetes is a major risk factor during the development of neuropathy. We aimed to assess the prevalence of diabetic peripheral neuropathy (DPN) in community-based population and risk factors associated with DPN in type 2 diabetic patients.

**Research design and method:** An urban community-based sample of 1099 adults in Shanghai was classified into normal glucose tolerance (NGT), impaired glucose regulation (IGR), Newly-diagnosed diabetes mellitus (NDM) and known diabetes mellitus (KDM). All the subjects were evaluated on complete foot examination. DPN was assessed by using neuropathy symptom score (NSS) and neuropathy disability score (NDS). Body mass index (BMI), waist hip ratio (WHR), fasting plasma glucose (FPG), 2-hour plasma glucose (2hPG), glycated haemoglobin (HbA<sub>1c</sub>), blood lipid and urinary albumin-to-

creatinine ratio (ACR) were investigated. DPN was defined as NDS $\geq$ 3 and NSS $\geq$ 5, or NDS $\geq$ 6. Data were compared among groups.

**Results:** The prevalence of DPN was 12.7% and 3.30% in the KDM and IGR patients respectively. The prevalence of DPN in NGT was only 0.4%. DPN was significantly associated with age (b: 0.098, S.E.: 0.028, OR: 1.103, CI: 1.044–1.166,  $P < 0.001$ ) and HbA1c (b: 0.523, S.E.: 0.128, OR: 1.687, CI: 1.312–2.169,  $P < 0.001$ ) by a logistic regression analysis.

**Conclusion:** Hyperglycemia was a strong risk factor for diabetic peripheral neuropathy. Peripheral neuropathy should be screened in IGR patients.

Table 1 - Multiple logistic regression analysis using DPN as a dependent variable

Variables	$\beta$	S.E. $\beta$	P	Odd ratio
Age	0.098	0.028	<0.001	1.103(1.044–1.166)
Sex	-1.429	0.482	0.003	0.239(0.093–0.616)
Waist circumference	0.041	0.02	0.045	1.042(1.001–1.084)
BMI	-0.059	0.061	0.332	0.943(0.837–1.062)
HbA1C	0.523	0.128	<0.001	1.687(1.312–2.169)
TG	0.016	0.14	0.911	1.016(0.772–1.336)
LDL	-0.154	0.297	0.604	0.857(0.479–1.535)

## 1156

### Screening for future glucose disturbances in subjects at risk of diabetes by a rapid and non invasive measurement of sweat function

J.-H. Calvet<sup>1</sup>, G. Mueller<sup>2</sup>, J. Dupin<sup>1</sup>, P. Schwarz<sup>2</sup>;

<sup>1</sup>Impeto Medical, Paris, France, <sup>2</sup>Prevention and Care of Diabetes, University of Dresden, Germany.

**Background and aims:** Several studies have shown a sweat dysfunction, witness of autonomic neuropathy, in people obese or at risk for type 2 diabetes. EZSCAN is a new quick and noninvasive technology to assess the sweat function at the palms and soles. It is based on the measurement of conductance resulting from the electrochemical reaction between the chloride ions of sweat and electrodes in contact with the skin. The purpose of this study was to compare this method with conventional measures of glucose tolerance and to evaluate its predictive for future disturbance in HbA1C in subjects with normal glucose tolerance at baseline.

**Materials and methods:** This study was conducted in 200 German subjects at risk for diabetes. The patients underwent an oral glucose tolerance test (OGTT) with measurement of the area under the curve (AUC) of glucose and insulin. Patients also completed a questionnaire to calculate their FINDRISC score. A subgroup of 76 patients received a follow up assessment after two years, among them 36 had a normal glucose tolerance at baseline. EZSCAN measurement of sweat function was performed with measurements of hands and feet electrochemical conductances (ESC) at baseline and follow-up investigation with computation of a risk score. Subjects were classified according to their sweat conductances and risk score into 3 groups: normal sweat function, moderately disturbed and highly disturbed.

**Results:** The mean age was  $56 \pm 14$  years and BMI  $28 \pm 5$  kg/m<sup>2</sup>. Depending on the values of hands and feet ESC, 43 subjects had a normal sweat function, 86 a function moderately disturbed and 71 a function highly disturbed. A significant difference was observed between the 3 groups in the AUC of glucose with the following respective values of  $836 \pm 174$ ,  $1009 \pm 202$  and  $1041 \pm 233$  mmol/Lmn,  $p < 0.0001$ . In 36 subjects with normal glucose tolerance at baseline, the AUC of the ROC curve for prediction of HbA1c  $\geq 5.7\%$ , two years later was 0.81 for the risk score EZSCAN while it was 0.54 for FINDRISC, 0.56 for fasting plasma glucose and 0.50 for 2h-plasma glucose (Figure).

**Conclusion:** This study shows that EZSCAN can be used for early detection of future glucose disturbance in subjects at risk. These results have to be confirmed on a larger population.

## 1157

### Prevalence of sudomotor dysfunction in type 2 diabetic patients attending diabetes clinics - a multicenter study

C.N. Manes<sup>1</sup>, N. Papanas<sup>2</sup>, T. Exiara<sup>1</sup>, S. Papantoniou<sup>3</sup>, E. Kirlaki<sup>4</sup>, S. Tsotoulidis<sup>5</sup>, N. Kefalogiannis<sup>4</sup>, E. Maltezos<sup>2</sup>;

<sup>1</sup>Diabetes Unit, General Hospital "Papageorgiou", Thessaloniki, <sup>2</sup>Diabetic Foot Clinic, Dimokritos University of Thrace, Alexandroupolis, <sup>3</sup>Diabetes Clinic, General Hospital of Kavala, <sup>4</sup>Diabetes Unit, Venizelion Hospital, Heraklion, Kreta, <sup>5</sup>Health Center, Kassandria, Halkidiki, Greece.

**Background and aims:** To investigate the prevalence of sudomotor dysfunction (SD) in type 2 diabetic patients on a multicenter study and assess any relation to overall nerve fibre damage.

**Materials and methods:** The study included 1010 type 2 diabetic patients randomly selected from those attending five (5) diabetes centers. There were 608 males (60.19%). Mean age and diabetes duration were  $63.90 \pm 10.26$  and  $12.24 \pm 7.75$  (yrs) respectively. A new indicator plaster method (neuropad) recently approved was used for the diagnosis of SD. Assessment of overall nerve fibre dysfunction was performed and graded clinically using the Neuropathy Disability Score (NDS). The plaster (colour blue) was applied for 10 minutes on the plantar aspect of the feet and the results recorded as pink, patchy (blue/pink), and blue. The abnormal result defined as patchy and/or blue indicated patients with SD.

**Results:** 1) 441 patients (43.7%) were found with SD - group A. They were older ( $66.74 \pm 8.78$  vs  $61.71 \pm 10.79$  yrs  $p < 0.0001$ ), had longer duration of diabetes ( $14.42 \pm 7.63$  vs  $10.54 \pm 7.42$  yrs,  $p < 0.0001$ ) in comparison with those ( $n = 569$ ) without any sign of SD - group B. 2) The signs of developed SD had 94.9% sensitivity and 70.2% specificity for overall fibre dysfunction. 3) Furthermore more severe peripheral somatic neuropathy (NDS  $6.85 \pm 5.59$  vs  $1.25 \pm 1.79$ ,  $p < 0.0001$ ) was detected in SD patients in comparison with those expressing normal SD tests. 4) In the logistic regression analysis age, diabetes duration but not sex were found to affect the development of SD ( $p < 0.05$ ).

**Conclusion:** The findings of the present study indicate that Sudomotor Dysfunction affects a large proportion of diabetic patients. The study also identifies the most important risk factors for SD, e.g. age, long diabetes duration. Proper foot care and education for this population is of great importance since SD is associated with peripheral nerve fibre damage.

## 1158

### Risk factors of impaired gastric emptying in patients with long-standing type 1 diabetes mellitus

T.T. Várkonyi<sup>1</sup>, R. Takács<sup>1</sup>, C. Lengyel<sup>1</sup>, M. Lázár<sup>2</sup>, M. Papós<sup>2</sup>, L. Pávics<sup>2</sup>, P. Kempler<sup>3</sup>, T. Wittmann<sup>1</sup>;

<sup>1</sup>1st Department of Medicine, University of Szeged, <sup>2</sup>Department of Nuclear Medicine, University of Szeged, <sup>3</sup>1st Department of Medicine, Semmelweis University, Budapest, Hungary.

**Background and aims:** Impaired gastric emptying is common among diabetic patients; however, its risk factors are poorly understood. The aim of this study was to identify potential risk factors of impaired gastric emptying among patients with long-standing type 1 diabetes mellitus.

**Materials and methods:** 54 patients with type 1 diabetes mellitus were included into the study (age: 37.1±1.74; duration of diabetes: 16.6±1.59 yrs; BMI: 24.1±0.46; HbA1c: 8.3±0.35%; mean±SE) The emptying of the stomach was evaluated by a scintigraphic gastric emptying procedure. Calculation of half-emptying time (HTE) characterized the stomach motility. Cardiovascular reflex tests were applied for the evaluation of autonomic neuropathy (AN). Three heart rate tests and two blood pressure tests were performed to assess the parasympathetic and sympathetic functions. Current perception thresholds were determined on the upper and lower limbs to study the sensory nerve integrity by a Neurometer (Neurotron Inc., Baltimore).

**Results:** The gastric emptying significantly correlated with the duration of diabetes, the age, the BMI and the HbA1c of patients (HTE-duration:  $r=0.33$ ,  $p<0.05$ ; HTE-age:  $r=0.43$ ,  $p<0.01$ ; HTE-HbA1c:  $r=0.27$ ,  $p<0.05$ ; HTE-BMI:  $r=0.33$ ,  $p<0.05$ ) A significant relationship was proven between the impaired gastric emptying and autonomic dysfunction (HTE-heart rate response to breathing:  $r=0.37$ ,  $p<0.01$ ; HTE-AN score:  $r=0.43$ ,  $p<0.01$ ). No association was found between stomach motility and sensory nerve function.

**Conclusion:** Among patients with long standing type 1 diabetes impaired gastric emptying was associated with age, diabetes duration, BMI and glycaemic control. There was a significant connection between impaired gastric motility and parasympathetic autonomic neuropathy. Effective management of risk factors, in particular, BMI and glycaemic control might contribute to the preservation of intact gastric motility in patients with type 1 diabetes mellitus.

## 1159

### Gustatory sweating - a common late diabetic complication?

T.S. Hansen, L. Tarnow;

Clinical Research Unit, Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** Gustatory sweating is a manifestation of autonomic neuropathy and is characterised by profuse sweating during or immediately after ingestion of food. It has been reported to occur more often in patients with long-standing diabetes with severe peripheral and autonomic neuropathy. Most reports on gustatory sweating have been case reports suggesting it to be a rare late diabetic complication. The aim of this study was to determine the prevalence of gustatory sweating in an unselected cohort of patients with type 1 diabetes.

**Materials and methods:** A questionnaire with 8 questions concerning gustatory sweating was designed and mailed to 745 patients with type 1 diabetes (49 % male, age: 51.5 ± 14.7 years, duration of diabetes: 26.7 ± 14.5 years, HbA1c: 8.1 ± 1.1 %) attending our outpatient clinic. The response rate was 89.3 %. Patients were classified as having gustatory sweating if they reported to suffer from sweating on the face, scalp or upper body during or immediately after ingestion of food. Patients with gustatory sweating indicated to have increased sweating as compared with others. Clinical data were extracted from patient records.

**Results:** A total of 43 (6.5 %) patients were classified as having gustatory sweating. Gustatory sweating was not associated with peripheral neuropathy, retinopathy or elevated albumin excretion rate. Patients with and without gustatory sweating were similar concerning sex, age, duration of diabetes, blood pressure and HbA1c. A trend towards a higher BMI in patients with diabetic gustatory sweating was seen (26.6 kg/m<sup>2</sup> vs 25.4 kg/m<sup>2</sup>,  $p = 0.06$ ). Patients with gustatory sweating more often also had gastroparesis: 18.6 % vs 5.2 %,  $p < 0.001$ .

**Conclusion:** Symptoms of diabetic gustatory sweating was seen in 6.5 % of patients with longstanding type 1 diabetes. Gustatory sweating was associated with symptoms of diabetic gastroparesis but not with other micro vascular complications.

## 1160

### Diabetic autonomic neuropathy in type 1 is associated with albuminuria, retinopathy, peripheral neuropathy, but in type 2 it is associated with pulse pressure and obesity

J. Fleischer<sup>1</sup>, K. Yderstraede<sup>2</sup>, E. Gulichsen<sup>3</sup>, P. Jakobsen<sup>4</sup>, H. Lervang<sup>4</sup>, E. Eldrup<sup>5</sup>, H. Nygaard<sup>6</sup>, L. Tarnow<sup>3</sup>, N. Ejlskjær<sup>1</sup>;

<sup>1</sup>Aarhus University Hospital, Department of Endocrinology and Internal Medicine, <sup>2</sup>Odense University Hospital, Department of Endocrinology, <sup>3</sup>Steno Diabetes Center, Gentofte, <sup>4</sup>Aalborg University Hospital, Department of Endocrinology, <sup>5</sup>Herlev Hospital, Department of Internal Medicine and Endocrinology, <sup>6</sup>Clinical Institute, Aarhus University, Denmark.

**Background and aims:** To identify the presence of cardiovascular autonomic neuropathy (CAN) in a cohort of individuals with diabetes in four outpatient clinics in Denmark and to evaluate the association between CAN and other risk factors.

**Materials and methods:** The DAN-Study is a Danish multi-center study focusing on diabetic autonomic neuropathy. Over a period of twelve months, 382 type 1 and 271 type 2 individuals with diabetes were tested for CAN. Patients were randomly recruited and tested during normal visits to outpatient clinics at four Danish hospitals. The presence of CAN was quantified by measuring cardiovascular reflex tests (Valsalva, response to standing and deep breathing) and analysis of heart rate variability in time and frequency domain. In order to describe possible associations, multivariate analysis with CAN as the dependent variable was performed.

**Results:** Besides heart rate above 80 ( $p<0.001$ ) and age above 60 years ( $p<0.02$ ) in both type 1 and type 2 patients multiple ordinal logistic regression analysis revealed that in type 1 diabetes patients CAN was associated with microalbuminuria ( $p=0.015$ ), macroalbuminuria ( $p=0.005$ ), and proliferative retinopathy ( $p=0.021$ ). Among type 2 diabetes patients CAN was associated with high pulse pressure ( $p<0.001$ ) and BMI above 35 kg/m<sup>2</sup> ( $p=0.025$ ).

**Conclusion:** In this cross-sectional observational study CAN is associated with proliferative retinopathy, micro- and macroalbuminuria in type 1 diabetes patients, whereas in type 2 diabetes patients CAN is associated with pulse pressure and obesity.

## 1161

### High prevalence of unawareness of having distal sensorimotor polyneuropathy in diabetes and pre-diabetes; the KORA F4 Study

B. Bongaerts<sup>1</sup>, W. Rathmann<sup>1</sup>, M. Heier<sup>2</sup>, B. Kowall<sup>1</sup>, D. Stöckl<sup>2</sup>,

C. Meisinger<sup>2</sup>, D. Ziegler<sup>3,4</sup>;

<sup>1</sup>Institute of Biometrics and Epidemiology, German Diabetes Center, Düsseldorf, <sup>2</sup>Institute of Epidemiology II, Helmholtz Zentrum München, Neuherberg, <sup>3</sup>Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, <sup>4</sup>Department of Metabolic Diseases, Düsseldorf University Hospital, Germany.

**Background and aims:** Distal sensorimotor polyneuropathy (DSPN) is a severe complication of type 2 diabetes. Whereas its prevalence is extensively studied, data on undiagnosed DSPN are sparse. The current study aimed to assess the prevalence of unawareness of having DSPN in pre-diabetes and diabetes, using a sample of the older population of Augsburg, South-Germany.

**Materials and methods:** Glucose tolerance status was determined in 61-82 year-old participants of the population-based KORA F4 Study (2006-2008) ( $n=1,100$ ). Clinical DSPN was defined as the presence of bilaterally impaired foot-vibration perception and/or bilaterally impaired foot-pressure sensation. DSPN cases were considered unaware of their condition when answering "no" to the question "has a physician had ever told you that you are suffering from nerve damage, neuropathy, polyneuropathy, or diabetic foot?"

**Results:** Clinical DSPN was prevalent in 154 (14%) participants, 140 of whom were unaware of their disorder (table). With 11 out of 46 subjects (23.9%, 95%CI: 12.6-38.8), participants with combined impaired fasting glucose and impaired glucose tolerance (IFG-IGT) had the highest prevalence of DSPN. Of these, 10 (91%) were unaware of having clinical DSPN. Participants with known diabetes had an equally high prevalence of clinical DSPN (22.0%, 95%CI: 16.2-28.9), with 30 out of the 39 (77%) cases with DSPN being unaware of having the disorder. Information on the performance of foot examinations was available for participants with known diabetes only ( $n=167$ ). In total of 113 (68%) subjects with known diabetes reported to have had their feet examined by a physician, whereas about a quarter reported to have never undergone a foot examination. A total of 38 out of 167 participants with known diabetes had clinical DSPN, 29 (76%) of whom were unaware of having the disorder.

**Conclusion:** Our findings show a high prevalence of unawareness of having clinical DSPN among subjects with IFG-IGT and with diabetes, and an insufficient frequency of foot examinations by a physician, suggesting an inadequate attention to diabetic foot prevention practice.

**Table:** Prevalence of clinical distal sensorimotor polyneuropathy, according to glucose tolerance status; KORA F4 (2006–2008)

	n	Prevalence clinical DSPN <sup>1</sup> (95% CI)	Unawareness of clinical DSPN <sup>2</sup>
Total study population (n=1,100)	154	14.0% (12.0–16.2)	91%
Normal glucose tolerance (n=577)	64	11.1% (8.6–13.9)	98%
Isolated-impaired fasting glucose (n=55)	3	5.5% (1.1–15.1)	100%
Isolated-impaired fasting glucose (n=183)	27	14.8% (10.0–20.7)	89%
Impaired fasting glucose - impaired glucose tolerance (n=46)	11	23.9% (12.6–38.8)	91%
Newly diagnosed diabetes (n=62)	10	16.1% (8.0–27.7)	100%
Known diabetes (n=177)	39	22.0% (16.2–28.9)	77%

CI: confidence interval, DSPN: distal sensorimotor polyneuropathy

<sup>1</sup> Defined as the presence of an impaired bilateral foot-vibration perception and/or an impaired bilateral foot-pressure sensation.

<sup>2</sup> Defined by a disaffirmative answer to the question “has a physician ever told you that you have nerve damage, neuropathy, polyneuropathy or diabetic foot?” in combination with the presence of clinical DSPN.

## 1162

### Small nerve fibre dysfunction is more pronounced than large fibre involvement in type 1 diabetes of forty years duration

K.A. Sveen<sup>1</sup>, B. Karime<sup>2</sup>, E. Jørum<sup>3</sup>, K. Dahl-Jørgensen<sup>3</sup>, S.I. Mellgren<sup>4</sup>, K.F. Hanssen<sup>1</sup>;

<sup>1</sup>Dept of Endocrinology, Oslo University Hospital, <sup>2</sup>Section of Clinical Neurophysiology, Oslo University Hospital, Rikshospitalet, <sup>3</sup>Dept of Pediatrics, Oslo University Hospital, Norway, <sup>4</sup>Dept of Clinical Medicine (Neurology), University of Tromsø, Norway.

**Background and aims:** Diabetic neuropathy is a major health problem that can lead to foot ulceration and lower limb amputation. Small fibers constitute 70–90% of peripheral nerve fibers and are suggested to be the earliest fibers to be damaged in diabetes. The prevalence of small fiber neuropathy and the mechanisms of its development are however not known in detail in long term type 1 diabetes. We therefore evaluated large and small nerve fiber function in a well characterized cohort with a long duration of type 1 diabetes by analyzing thermal thresholds and intraepidermal nerve fiber density (IENFD) in the skin, HbA1c and the advanced glycation endproduct Nepsilon-(carboxymethyl) lysine (CML) in serum.

**Materials and methods:** Twentyseven persons (53±7 years) with type 1 diabetes of 40±3 years duration from the “Oslo study cohort” underwent neurophysiological investigations of large- and small nerve fibers. Symptom evaluation and neurological examination were performed. Large fiber function was assessed by nerve conduction studies (NCS), small fibers by quantitative sensory thresholds (QST) and IENFD from the distal leg for quantification of small nerve fibers. HbA1c was measured prospectively for 27 years. The advanced glycation endproduct CML (Carboxymethyllysine) was measured ten years prior to these examinations by immunoassay.

**Results:** Only 30% reported sensory symptoms. NCS were normal in 11 (41%) patients. The remaining 16 displayed abnormal findings compatible with neuropathy, slight in four, moderate in eight and severe in four patients. All patients with symptoms had abnormalities on NCS. Thermal thresholds in the feet and at the level of the knee were elevated in the patients compared to healthy controls. Twentytwo (81%) patients were diagnosed with small fiber dysfunction (cold detection <25 °C on the dorsum of the feet and/or warm

detection >43 °C), either a pure small fiber neuropathy (with normal NCS) in 7 patients or a small fiber dysfunction in addition to large fiber neuropathy (n=15). IENFD was abnormal in 19 (70%) and significantly lower in diabetic patients than in age matched controls (4.3 mm±2.3 vs 11.2 mm±3.5, p<0.001). IENFDs were negatively correlated to warm threshold temperature in the leg (r=-0.56, p=0.002), knee (r=-0.52, p=0.005) and heat-pain threshold in the leg (r=-0.57, p=0.002). Mean HbA1c over 27 years correlated negatively with IENFD (r=-0.4, p=0.043), heat-pain threshold in the hand (r=-0.5, p=0.02) and to cold detection threshold (r=-0.6, p=0.002). In a multivariate linear regression model including age, height, BMI and CML, all were significantly associated with low IENFD (adjusted R<sup>2</sup>=0.57).

**Conclusion:** Small fiber sensory neuropathy presenting with reduced IENFD densities and correlated warm thresholds evaluated by QST is a major manifestation in type 1 diabetes of forty years duration, and is more pronounced than large fiber neuropathy evaluated clinically and by nerve conduction. HbA1c and the advanced glycation endproduct CML seem to be important factors in the development of small fiber damage in long term type 1 diabetes. Our findings may indicate that CML has a predictive value in the development of small fiber dysfunction in type 1 diabetes.

### A 16-year prospective study of autonomic nerve function in type 1 diabetic patients: association with autoimmunity to nervous tissue structures

E. Favaro<sup>1</sup>, A. Raviolo<sup>1</sup>, E. Coppo<sup>1</sup>, K. Bonomo<sup>2</sup>, P. Passera<sup>1</sup>, P. Massucco<sup>2</sup>, A. Blatto<sup>3</sup>, A. Grassi<sup>4</sup>, G. Grassi<sup>1</sup>, M. Porta<sup>1</sup>, P. Cavallo Perin<sup>1</sup>, R. Quadri<sup>1</sup>, M.M. Zanone<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, University of Turin, <sup>2</sup>Ospedale San Luigi Gonzaga, University of Turin, Orbassano, <sup>3</sup>Ospedale Maria Vittoria, Divisione di Diabetologia, <sup>4</sup>Ospedale Mauriziano, Divisione di Diabetologia, Turin, Italy.

**Background and aims:** Data on the early stage and the natural history of autonomic and somatic neuropathy in type 1 diabetes are scanty. Studies have linked autoimmunity to autonomic nervous tissue structures and autonomic neuropathy. To evaluate prospectively this association, we monitored autonomic function and the presence of autoantibodies (Ab) to sympathetic and parasympathetic nervous structured in a cohort of young type 1 diabetic patients.

**Materials and methods:** One hundred and twelve young type 1 diabetic patients (age >11 years, disease duration > 3 years) were recruited between 1995–1997 (time 1). Anti-vagus nerve and anti-cervical ganglia Ab were detected in 28 patients (14 patients had anti-vagus Ab, 14 had anti-cervical ganglia Ab, 1 had both Ab), by indirect IF complement-fixation technique. 92 (82%) patients were re-evaluated at time 2 (40 ± 3 months from time 1), and 57 (51%, -of whom 48 completed all tests) were re-evaluated at time 3 (16.6 ± 5 years from time 1) (age 31 ± 2 years, disease duration 23 ± 4 years). A standard direct enquiry for autonomic and peripheral sensory-motor symptoms was made; neurological function was assessed by performing four cardiovascular (CV) tests (deep breathing test, DB; 30/15 ratio; Valsalva ratio, VR; blood pressure drop on standing, BP), clinical and neurological examination, vibratory perception threshold (VT) measurement.

**Results:** At time 3 follow-up, CV test values were significantly lower compared to time 1 and time 2 values. Dividing the patients according to the nervous tissue Ab status, one test was borderline in 6 (6/34, 17%) Ab- patients, and one or more tests abnormal in 9 (9/14, 64%) Ab+ patients [1 test (4 pz), 2 tests (3 pz) o 3 tests (2 pz)] (p<0.05), and time 3 CV test values were lower amongst the Ab+ compared to Ab- patients (p=0.05 only for DB test). Amongst the Ab+ patients, one patient reported gustatory sweating and one had BP drop > 20 mmHg. VT was significantly higher amongst patients with depressed reflexes (n=15), and 6 patients (4 with depressed reflexes) developed symptoms of peripheral somatic neuropathy (3 patients with carpal tunnel). There was no association between neurological parameters, presence of microvascular complications and metabolic control. Mean HbA1c value of the past 1 year (7.7% ± 1.3) significantly correlated with the mean of the 5 past years (7.8 ± 1).

**Conclusion:** The preliminary results of the ongoing prospective study of a cohort of type 1 diabetic patients indicate that symptomatic autonomic neuropathy is not characteristic of young diabetic patients, but autoantibodies to autonomic structures are associated with subtle autonomic dysfunction.

## PS 101 Foot ulceration and amputation: treatment outcomes

1164

**Time of healing of foot ulcers among patients with type 1 and type 2 diabetes have decreased in the period 2001 - 2010**

A. Nielsen, T.P. Almdal, K.E. Nielsen, U. Bjerre-Christensen, A. Rasmussen, P. Holstein;

Steno Diabetes Center, Gentofte, Denmark.

**Background and aim:** Foot ulcers are a very costly complication among diabetes patients. If the time from diagnosis to healing of the ulcer can be reduced this will decrease the costs. To our knowledge there are no longitudinal studies of change in healing time of foot ulcers among diabetes patients. The aim of the present study was to study the possible changes in healing of foot ulcers in two large cohort of type 1 diabetes patients (T1D) and type 2 diabetes patients (T2D) in the period 2002-2010.

**Methods:** Our clinic is a specialized diabetes clinic. The clinic has a multidisciplinary foot care team and is an integrated part of the public health care system in the greater Copenhagen area. In the clinic app 3500 patients with T1D and app 2000 patients with complicated T2D are followed. When a foot ulcer is observed the patients is seen immediately by the podiatrist and if necessary a specialist in orthopedic surgery within at max 1 week. At the initial visit it is determined whether etiology of the ulcer is neuropathic or ischemic. Standard treatment consist of therapeutic footwear with individual off-loading, antibiotics if infection, surgical drainage when required, referral to corrective surgery or vascular surgery if indicated, and education. Patients are seen with 1-6 weeks interval until healing of the ulcer. All information in relation to the patients, including date of diagnosis as well as date of complete healing of ulcers is housed in an electronic patient record system. We studied the healing time of foot ulcers, the number of visits until healing, the number of days without an ulcer before a new ulcer occurred, and the development in these figures over a nine years period.

**Results:** In the 2002-04 a total of 548 ulcers (60% toe ulcers) were diagnosed, in 2005-07 a total of 627 ulcers (55% toe ulcers) were diagnosed, and in the period 2008-10 a total of 654 (57% toe ulcers) were diagnosed. 62 % of the ulcers were diagnosed among T2D patients and 38 % among T1D patients. For all foot ulcers healing time decreased from 104 in 2002-04 to 83 days in 2008-10. For T1D patients healing time decreased from 111 to 84 days in the period. For T2D patients healing time decreased from 99 to 82 days. The figure shows change in treatment time in relation to toe ulcers. In 2002-04 patient were seen 5 times (median) in the foot clinic before healing of the ulcer, in 2008-10 this was reduced to 3 times (median). Among patients where ulcers healed in 2002 45 % were free of any new diabetic ulcer in the subsequent 3 years, among patients where ulcers healed in 2008 55 % were free of any ulcers in the subsequent 3 years.

**Conclusion:** The present study shows that healing time of ulcers treated in a specialized diabetes clinic have decreased substantially in both patients with T1D and T2D, however most pronounced among patients with T1D.

**Days of treatment ulcers on toes, median, upper and lower quartile**

1165

**Reduction of major amputations in diabetics after the introduction of a multidisciplinary team for the diagnosis and treatment of diabetic foot**  
S. Acquati, L. Gagliardi, A. Tartaglia, L. Buci, S. Taroni, E. Gozzo, M. Nizzoli;  
Endocrinology and metabolic disease Unit, Forlì, Italy.

**Background and aims:** Lower extremity amputation (LEA) is one of the most feared diabetic complications. 15-25% of diabetics will develop a foot lesion during their life. Despite of a precocious and intensive treatment these lesions can take weeks or months to heal. This can determine a physical inability and especially a reduction in quality of life. A lesion can also often precedes a major limb amputation. Several studies show how a prompt and precocious treatment by a multidisciplinary team is able to reduce the risk of LEA. Since 2007 in Forlì area (Northern Italy) diabetic foot was managed by different specialist in a chaotic way. In September 2007 it was created a multidisciplinary team for the diagnosis and treatment of diabetic foot coordinated by an endocrinologist, expert in this field. LEA is considered a marker of the quality of foot care in diabetics. Aim of the study was to verify the efficacy of the introduction of a multidisciplinary diabetic foot approach in our hospital evaluating the trend of amputation rate from 2005 to 2011.

**Materials and methods:** All major LEAs from 1 January 2005 to 31 December 2011 were identified. We used hospital discharge data to identify patients. We selected the procedure codes 8415 and 8417 (non traumatic major amputation) from 2005 until 2011. Then we analyzed the principal and/or secondary diagnosis of diabetes (ICD-9 codes 250) and we divided the patients who underwent a major amputation in two group: group D (patients affected by diabetes) and group ND (patients not affected by diabetes). We also used as data source diabetes register of Forlì. We evaluated the number of major LEAs from 2005 to 2011, the age of patients and duration of hospitalization (days) in both groups.

**Results:** From 2005 until 2011 we registered n° 68 major limb amputation in Forlì (D 31/68% - 45,5% vs ND 37/68 - 54,4 %). At the 2005 census Forlì had a population of 155503, predominantly white caucasian; at 2006 population was 155612; at 2007 it was 155728; at 2008 it increased to 157261; at 2009 population was 158417; at 2010 it was 158823 and 158913 at 2011. We observed a reduction in major amputation hospitalization rate from 2005 until 2011 in diabetic population compared to general population (see graph below). The analysis of clinical data showed an older age in general population (D 75.6±7.3 yrs vs ND 82.9±3.9 yrs, p=0.038). We didn't see a significant difference in days of hospitalization between the two group (D 29.4±19.4 days vs ND 41.6±27.5 days, p=n.s.).

**Conclusion:** This study shows that a multidisciplinary approach for the diagnosis and treatment of diabetic foot, structured and coordinated by a specialist, reduce the major LEAs rate in diabetics and seems to slightly reduce the days of hospitalization.

**Strategy to improve diabetic foot care: results of 7-year prospective study from implementation to global approach**

R. Anichini<sup>1</sup>, A. Tedeschi<sup>1</sup>, S. Baroncelli<sup>1</sup>, A. Bernini<sup>1</sup>, L. Barbanera<sup>1</sup>, G. Seghieri<sup>1</sup>, M. Marini<sup>2</sup>, R. Salvadori<sup>2</sup>, A. De Bellis<sup>1</sup>;

<sup>1</sup>Internal Medicine, Diabetes Unit, <sup>2</sup>Società Salute, Public Health Area, Pistoia, Italy.

**Background and aims:** In 2007 we published the results of a 5-year period study (1999-2003), performed to evaluate whether the implementation of a

programme for prevention and treatment of diabetic foot lesions could decrease the number of amputations in the area of our interest (Pistoia, 171,000 inhabitants). Following the establishment of a strategy including prevention, patient and staff education, multidisciplinary treatment of foot ulcers and close monitoring, diabetic foot care resulted greatly improved in terms of lower extremity amputations and final outcome of the lesions. The implementation of the International Consensus on Diabetic foot lesions in Pistoia was introduced in Pistoia at level of Primary Care (Health Care District, general practitioners), and at level of Secondary Health Care through the creation of a multidisciplinary care team at the hospital, including the diabetologist, specialized nurses, podiatrist, orthopaedic surgeon and cardiologist. Recently, the collaboration with GPs has been further reinforced through the development of the Chronic Care Model (CCM) which ensures to patients an integrated assistance between GPs and specialists (2009). The aim of the present study was to evaluate:

1. the increasing percentage of patients referred to our unit for diabetic foot lesions, who underwent a structured educational programme including footwear during years 2004–2011,
2. the possible reduction of the number of severe foot lesions and of amputations occurring during these years,
3. the increasing number of revascularization procedures performed in the same period of time.

**Materials and methods:** Clinical records are kept by the diabetologist and the database for this study was taken from DRG Tuscany database, from Eurotouch® and CCM database

**Results:** The data of this study demonstrate:

1. a 40% increase of patients referred for the first time to our unit (from 496 in 2004 to 806 in 2011) who underwent the primary prevention educational programme including foot care,
2. a significant reduction of numbers of lesions seen (45%) (from 340/years in 2004 to 186 ys in 2011) and reduction lesions with a high grade (WTCS) of severity (>2) (20%) in outpatients of the observation of severe foot lesions (gangrene and serious infections)
3. a reduction of incidence of major amputations (from 3 x 100000 inhabitants in 2004, to 1.8 in 2011;  $p < 0.01$ ), while a different trend was observed concerning minor amputations, with an incidence rate of 3,5 in 2004 and 6,2 in 2011.
4. following the increasing collaboration with the cardiologist dedicated to revascularization procedures, an increasing number of below knee endovascular procedures (BKEP) has been performed (from 10 in 2004 to 120 in 2011).
5. in these periods outpatients treated by podiatrist in primary and secondary prevention were increased from 160 to 922.

**Conclusion:** Analysis of these preliminary data show that, following the implementation of ICDF on Diabetic Foot a significant improvement of foot care in diabetic patients has been observed, and in the period of our observation the percentage of the patients seen by the foot care team has become progressively higher, such that now in the health area of our interest all diabetic patients are screened for diabetic foot every years and patients with high risk of ulceration or with diabetic foot are referred to the local Diabetic foot unit.

## 1167

### Therapeutic footwear of 54 patients with Charcot diabetic foot

G. Ha Van;

Diabetologia PR Hartemann, Hôpital Pitié - Salpêtrière, Paris, France.

**Background and aims:** After healing a plantar ulcer on deformation of a Charcot foot we studied the recurrence of the ulcer after therapeutic footwear. The objective was to study the avoidance of surgical correction of deformation of the Charcot foot by made to measure shoes.

**Materials and methods:** We followed prospectively 54 diabetic patients with Charcot foot. 46/54 patients had a history of ulcer which was healed by off loading. Every patient (n=54) has got a therapeutic footwear made in our team by the same shoe-maker. We studied the recurrence or the occurrence of plantar ulcers and the average duration of wearing of the footwear.

**Results:** 5% of the 54 patients had a history of plantar ulcer on the Charcot foot deformation 100% of ulcers healed (average duration of ulcer: 241 days). The average data were: age: 58 years diabetes age: 18 years, type 2 diabetes : 98%, BMI: 28.6, Right foot: n=20 Left Foot n= 20, 10 Bilateral Charcot foot, 92% had a midfoot localisation. Average duration of follow up of the wearing of therapeutic shoes:  $882 \pm 899$  days. Average duration of daily use of the shoes:  $7 \pm 5$  hours per day  $2 \pm 2$  hours of walking, average distance of walking without stopping:  $1559 \text{ m} \pm 2324$ . Amputation: below-knee: 3%, toe:

3%, death: 3%. Rate of recurrence of ulcer on the deformation of the Charcot Foot = 9%.

**Conclusion:** Corrective surgery of the Charcot foot (92% of midfoot localisation) has been avoided by wearing therapeutic footwear made by our specialised team: 91% of absence of plantar ulcers after 882 days of follow-up.

## 1168

### Eight year outcomes of a consecutive single centre series of patients presenting with osteomyelitis of the foot in diabetes

W.J. Jeffcoate, F.L. Game;

Diabetes and Endocrinology, Nottingham University Hospitals Trust, UK.

**Background and aims:** To determine the outcome at 5 and 8 years of patients newly diagnosed with osteomyelitis of the foot in diabetes.

**Materials and methods:** Observational study of a consecutive series managed at a single centre.

**Results:** The baseline data of this series of 147 patients has been previously published, together with outcomes at 12 months. Mean age was 64.7 years, 66% men. There was an apparent resolution of bone infection in 63.3% cases, and 23% of the population had had a minor amputation and 8.8% had had a major amputation by 12 months. Full 8 year outcome data are available in 138 (93.9%) of the 147 patients. By 5 years a total of 37 (26.8%) had had minor amputations on the side of the original lesion, and 12 (8.6%) had had a minor amputation on the other side. 18 (12.9%) had had a major amputation on the ipsilateral side and 6 (4.3%) had had one on the contralateral side, including one with bilateral limb loss. 71 (51%) of the series had died within 5 years. By 8 years there had been a further 3 minor amputations on the index limb (total 8 year ipsilateral minor amputations, 28.9%), a further 6 contralateral minor amputations (total 13%). There had been 2 further major amputations (1 ipsilateral and 1 contralateral), leaving a total of 17.7% who had lost one or both limbs by this time. 61.9% of the cohort had died by 8 years, in a median of 33 (range 1–96) months post presentation. In those who had major amputation the median time to death was 31 (range 1–78) months post amputation.

**Conclusion:** The long term outcome for patients newly diagnosed with osteomyelitis of the foot in diabetes is poor with over half dying before 5 years of follow-up. The poor prognosis is factor that should be taken into account when considering the options for long-term management. Despite this, there is no evidence that the relatively conservative approach to the management of this series resulted in a worse outcome than any previously reported.

## 1169

### Neurotensin and collagen dressings improve diabetic wound healing

L. Moura<sup>1,2</sup>, A. Dias<sup>2</sup>, E. Suesca<sup>3</sup>, S. Casadiegos<sup>3</sup>, M.F. Duque<sup>3</sup>, H. Sousa<sup>2</sup>, E. Carvalho<sup>1,4</sup>;

<sup>1</sup>Center for Neuroscience and Cell Biology, Coimbra, Portugal, <sup>2</sup>CIEPQPE, Chemical Engineering Department, University of Coimbra, Portugal,

<sup>3</sup>Pharmacy Department, Universidad Nacional de Colombia, Bogotá,

Colombia, <sup>4</sup>APDP, The Portuguese Diabetes Association, Lisboa, Portugal.

**Background and aims:** Impaired wound healing is an important clinical problem in diabetes and results in failure to completely heal diabetic foot ulcers (DFU), leading to lower extremity amputations. Recent studies indicated that neuropeptides like Substance P, NPY, and CRH may act as inflammatory modulators and may improve the diabetic wound healing process. However, to enhance the DFU wound healing process, wounds should be dressed with appropriate biomaterials to protect and avoid contaminations and to provide a sustained and effective release of bioactive substances. Collagen and chitosan biopolymers have been used for this purpose due to its favorable properties such as biocompatibility, biodegradability, non-toxicity and favorable biological behavior. The aim of this work is to use a wound dressing system for neurotensin delivery, into the wound, using collagen as biopolymer dressing.

**Materials and methods:** Animal model: Diabetes was induced by an intraperitoneal injection of 200mg/kg streptozotocin (STZ) dissolved in 200ml citrate buffer (pH 4.2) or buffer alone (non-diabetic mice). Control or STZ-treated mice were anesthetized and two 6 mm excision wounds, 2 cm apart, were created dorsally using a punch biopsy tool. A film of collagen alone, NT alone (50ug/wound/per day), collagen loaded with NT (50ug/wound/per day) or PBS were placed daily on wounds till total healing and the progress of wound closure was monitored by acetate tracing up to 10 days. Tissue analysis: Gene expression of inflammatory factors (TNF-alpha, IL-6) and

MMP-9 involved in the wound healing pathways were measured by real-time RT-PCR.

**Results:** In diabetic mice, collagen treated wounds showed a reduction in the wound area as compared to PBS treated wounds (13%), NT treatment alone showed a reduction of (14%), while it is with the combination of the two treatments that we observed the greatest reduction in wound area (19%,  $p < 0.01$ ), effects were significant already at 3 days post-wounding. A major expression of inflammatory factors is observed at day 3 compared to day 0 in non-treated wounds. At day 3, both TNF- $\alpha$  and IL-6 are up regulated in controls and diabetic mice while this effect decreased back to day 0 levels in non-treated wounds. Similar results are observed for MMP-9. Collagen alone significantly decreased TNF- $\alpha$  ( $p < 0.05$ ) and MMP-9 ( $p < 0.05$ ) gene expression in diabetic compared with control mice at day 3. At day 10 post-wounding, similar results were observed. In addition, at day 3, collagen in combination with NT decreased the highly expressed TNF- $\alpha$  and MMP-9 observed with NT treatment in diabetic mice. Under these conditions, NT alone, at day 3, seems to induce TNF- $\alpha$  and MMP-9 expression and collagen treatment decreased this effect.

**Conclusion:** Results demonstrate that collagen alone or in combination with NT potentially decrease the inflammatory conditions observed in the wound at day 3, making it a potentially advantageous wound dressing for the treatment of diabetic foot ulcers.

## 1170

### Intravenous antimicrobial therapy for patients with diabetic foot ulcers: an effective outpatient program in Tanzania

Z.G. Abbas<sup>1,2</sup>, J.K. Lutale<sup>1</sup>, L.K. Archibald<sup>3</sup>;

<sup>1</sup>Internal Medicine, Muhimbili University of Health and Allied Sciences,

<sup>2</sup>Abbas Medical Centre, Dar es Salaam, United Republic of Tanzania,

<sup>3</sup>Infectious Diseases, College of Medicine, University of Florida, Gainesville, USA.

**Background and aims:** Foot ulcers cause substantial morbidity and mortality among persons with diabetes in Tanzania, and are associated with prolonged hospital stays and increased hospital costs. Because of these costs, and limited inpatient services and available beds, we initiated a program for instituting intravenous (IV) antimicrobial therapy in the diabetes outpatient clinics at two major centers in Dar es Salaam, Tanzania.

**Materials and methods:** During February 2005–December 2011 (study period), all adult patients with diabetes who presented at diabetic clinic at two diabetes centres in Dar es Salaam, Tanzania with infected foot ulcers were evaluated then started on courses of IV antimicrobials for 10–20 days. Patients were followed up daily by a trained nurse assistant for daily IV antimicrobials, ulcer assessments, and dressing changes at the two centres outpatient clinics. Antimicrobial therapy included various combinations of second and third-generation cephalosporins, penicillins, macrolides, quinolones, and anti-anaerobic agents.

**Results:** Logistic regression analysis was carried out and adjusted odds ratio (AOR) and 95% confidence intervals (CI) were calculated. Of 909 patients who were treated during the study period, 595 (65%) were male; median age and duration of diabetes was 55 years and 8 years, respectively. Nine hundred patients received an extended spectrum third-generation cephalosporin; complete ulcer healing was attained in 760 (84%). Independent factors associated with poor ulcer healing included macrovascular disease (AOR: 2.1, CI: 1.4–3.2); hypertension (AOR: 1.6, CI: 1.04–2.4); and concomitant administration of amoxicillin/clavulanic acid (AOR: 2.7, CI: 1.5–4.7) or quinolones (AOR: 5.1, CI: 3.3–7.9). Independent factors associated with complete ulcer healing included palpable peripheral foot pulses (AOR: 3.1, CI: 2.1–4.5), ulcers of area  $< 1,000 \text{ mm}^2$  (AOR: 2.1, CI: 1.4–3.1), or concomitant receipt of an anti-anaerobic agent (AOR: 4.5, CI: 3.0–6.8). No deaths or side effects were documented.

**Conclusion:** We established the feasibility of affordable, outpatient IV antimicrobial therapy in the management of infected diabetic foot ulcers in Tanzania. Complete healing was realized in 84% of patients with best outcomes documented among patients who received a single extended spectrum third-generation cephalosporin along with an anti-anaerobic agent. Addition of other antimicrobial agents, including penicillins, macrolides, or quinolones, did not enhance ulcer healing rates. These findings potentially have cost saving implications for the management of infected diabetic foot ulcers in Tanzania.

## 1171

### Randomised, double-blind versus placebo, proof of concept clinical trial to evaluate efficacy and safety of g.68.γ/etoh in diabetic infected foot ulcers (DANTE study)

M. Monami<sup>1</sup>, S. Genovese<sup>2</sup>, R. Anichini<sup>3</sup>, C. Fondelli<sup>4</sup>, F. Romagnoli<sup>5</sup>, N. Bartoli<sup>1</sup>, G. Clerici<sup>2</sup>, G. Navales<sup>6</sup>, E. Mannucci<sup>1</sup>, G. Gensini<sup>1</sup>;

<sup>1</sup>AOU Careggi, Florence, <sup>2</sup>IRCCS Multimedica, Milan, <sup>3</sup>Azienda USL 3,

Pistoia, <sup>4</sup>Policlinico Le Scotte, Siena, <sup>5</sup>INRCA, Ancona, <sup>6</sup>L. Molteni & C.,

Florence, Italy.

**Background and aims:** RLP068/Cl is a photosensitizer compound coming from an original Italian research that showed pharmacological activity in reducing the bacterial load in vitro and in vivo models. The activity of RLP068/Cl is due to the production of singlet oxygen or other reactive oxygen species (ROS), generated through its activation by red light released by laser machine. The efficacy of activated RLP068/Cl was evaluated in vitro and in vivo models against a wide range of bacteria and yeast. No evidence of bacterial resistance was seen. RLP068/Cl (formulated into a gel formulation G.68.γ/EtOH) was found to be well tolerated in a previous trial. The object of the present trial was to demonstrate the proof of concept of the activity and tolerability of RLP068/Cl (into gel G.68.γ/EtOH) in reducing the bacterial load in infected diabetic foot ulcers.

**Materials and methods:** 62 diabetic patients with infected foot ulcers were randomized to placebo or to G.68.γ/EtOH gel (0.1%, 0.3% o 0.5%). After a mild sharp debridement in the peripheral area, gel was applied on the ulcer and after 1 hour from the application, each ulcer was illuminated with red light (689 nm) for 500 sec. The primary endpoint was the reduction of bacterial load between pre-treatment and immediately after illumination as measured by an ulcer sample drawn with a flocked nylon swab. Starting from post-illumination swab collection, all patients received an antibiotic treatment (amoxicillin trihydrate/clavulanic potassium) and they were followed for two weeks.

**Results:** Immediately after the photoactivation of the gel, total bacterial load was reduced with the active treatment 0.3% and 0.5% in respect to placebo (placebo,  $m \pm SD$  from  $4.7 \pm 0.9$  to  $3.7 \pm 1.7$  LogCFU/ml; G.68.γ/EtOH 0.1%: from  $4.4 \pm 0.8$  to  $2.5 \pm 2.0$  LogCFU/ml; G.68.γ/EtOH 0.3%: from  $4.8 \pm 0.8$  to  $1.9 \pm 1.9$  LogCFU/ml; G.68.γ/EtOH 0.5%: from  $4.4 \pm 1.0$  to  $1.4 \pm 1.7$  LogCFU/ml) with a statistical significance ( $p < 0.001$ ). This effect is still present but less evident after 3 days. Moreover the two treatments (0.3% and 0.5%) resulted in a reduction of about 3 log respect to pre-treatment. No serious adverse events related to the study drug were recorded.

**Conclusion:** The results of the study showed that RLP068/Cl is able to reduce the bacterial load in infected diabetic foot ulcers. This effect, demonstrated for the first time in patients, strongly confirms the pre-clinical data and supports the development of RLP068/Cl as an innovative treatment for infected diabetic foot ulcer.

## 1172

### Topical allogeneic mesenchymal stem cell therapy for diabetic ulceration

A. O'Loughlin<sup>1</sup>, M. Kulkarni<sup>2</sup>, M. Creane<sup>1</sup>, E.E. Vaughan<sup>1</sup>, E. Mooney<sup>1</sup>, G. Shaw<sup>1</sup>, M. Murphy<sup>1</sup>, P. Dockery<sup>3</sup>, A. Pandit<sup>2</sup>, T. O'Brien<sup>1</sup>;

<sup>1</sup>Regenerative Medicine Institute, <sup>2</sup>Network of Excellence for Functional

Biomaterials, <sup>3</sup>Department of Anatomy, National University of Ireland,

Galway, Ireland.

**Background and aims:** Non-healing diabetic foot ulceration results in a significant burden on individual patients' health and health-care system resources. Typically applied mesenchymal stem cells (MSCs) provide a new treatment approach for reducing time to wound healing. MSCs are known to promote angiogenesis. We tested the hypothesis that topically applied allogeneic MSCs increase wound healing and support angiogenesis.

**Materials and methods:** A topical cell based therapy was developed by seeding allogeneic non-diabetic bone-marrow derived MSCs in a type 1 collagen scaffold. The cells were delivered to a full thickness cutaneous wound in the alloxan-induced diabetic rabbit ear ulcer model at increasing doses. The animals remained hyperglycaemic for the duration of the study (5 weeks). The experiments were performed under license from the Department of Health with ethical approval from the National University of Ireland, Galway ethics committee. The groups analysed included untreated wounds and wounds treated with either collagen scaffold alone, collagen seeded with 50,000,

100,000 or 1,000,000 MSCs. 5 wounds were analysed per animal. Percentage wound closure after 1 week was assessed using wound tracings. Stereology was used to assess the new vascular bed in the wounds.

**Results:** 1,000,000 MSCs demonstrated significantly increased percentage wound closure in comparison to untreated wounds. Analysis between groups was by ANOVA and post-hoc Fisher's test. Statistical significance was taken as  $p < 0.05$ . Collagen and MSC-seeded collagen scaffolds demonstrated increased surface density of blood vessels and decreased radial diffusion distance when compared to controls. New blood vessels were longer had more convoluted in wounds treated with collagen seeded with 1,000,000 MSCs.

**Conclusion:** Allogeneic non-diabetic MSCs seeded in a collagen scaffold demonstrate superior cutaneous wound healing in a pre-clinical model of diabetic ulceration. Collagen and collagen seeded with MSC treatments result in increased angiogenesis when compared to untreated wounds but statistically significant increased wound healing was observed only at the higher dose of 1,000,000 MSCs. This MSC therapy delivered using a collagen scaffold leads to augmented wound healing with increased angiogenesis, which is a central pathological feature in the non-healing diabetic foot ulcer.

## PS 102 Mechanisms and treatment of diabetic neuropathy

1173

### Cerebrovascular reactivity in patients with long-term type 1 diabetes mellitus with and without cardiovascular autonomic neuropathy

B.N. Mankovsky<sup>1</sup>, Y. Saenko<sup>2</sup>, A. Kovalenko<sup>2</sup>, O. Likhoshapko<sup>1</sup>;  
<sup>1</sup>National Medical Academy of Postgraduate Education, <sup>2</sup>Institute of Endocrinology and Metabolism, Kiev, Ukraine.

**Background and aims:** Diabetes mellitus is associated with the significantly increased risk of stroke, cognitive impairments and dementia. One of the possible underlying mechanisms of these disorders could be the impairment of cerebrovascular reactivity (CVR). Cardiovascular autonomic neuropathy (CAN) is established risk factor for stroke in patients with diabetes. However, the possible association of impairments of CVR and CAN was not studied. Therefore, the aim of this study was to investigate CVR in patients with long-term type 1 diabetes mellitus with and without CAN.

**Materials and methods:** We examined 35 subjects - 7 with type 1 diabetes mellitus and CAN (aged  $48.0 \pm 4.1$  year, diabetes duration -  $24.3 \pm 5.9$  year,  $HbA_{1c}$  -  $9.2 \pm 0.6\%$ ) (data are presented everywhere as mean  $\pm$  SEM), 13 patients with diabetes and no CAN (aged  $37.8 \pm 2.9$  year, diabetes duration -  $13.5 \pm 1.2$  year,  $HbA_{1c}$  -  $8.0 \pm 0.4\%$ ) and 15 healthy subjects as controls (aged  $47.9 \pm 2.7$  year). The subjects studied did not have any history of cerebrovascular disorders. The patients did not take any medications or products which could affect CVR. The diagnosis of CAN was based on Ewing battery of tests assessing R-R variability in electrocardiogram and diagnosis of CAN was confirmed in those patients who had more than 2 abnormal tests. The mean cerebral blood flow velocity by the middle cerebral artery (MCA) in both sides was measured by transcranial dopplerography at basal condition and immediately after the breath-holding for 30 sec and after application of the ice for 5 sec. CVR was calculated as the changes of the mean blood flow velocity by MCA immediately after the probe relative to the basal value expressed in percentage.

**Results:** Mean cerebral blood flow velocity by the right and left MCA at the basal conditions was not different in patients with type 1 diabetes with and without CAN and control group. We found that in patients with type 1 diabetes mellitus either with or without CAN there was significant decrease of CVR compared to the control group after the both probes. However, there was no significant difference in CVR after both probes between group of diabetic patients with and without CAN. CVR after the breath-holding in the right MCA was  $17.2 \pm 1.81\%$ ,  $14.8 \pm 1.49\%$  and  $28.55 \pm 3.18\%$  and in the left MCA was  $16.2 \pm 2.9\%$ ,  $14.0 \pm 1.66\%$  and  $24.8 \pm 2.87\%$  in patients with and without CAN and controls, respectively,  $p < 0.05$  for comparisons between both groups of patients with diabetes and controls. After the cold test CVR was  $17.7 \pm 2.48\%$ ,  $19.6 \pm 1.65\%$  and  $28.0 \pm 2.53\%$  at the right side and  $19.6 \pm 4.37\%$ ,  $17.6 \pm 2.69\%$  and  $24.7 \pm 1.63\%$  at the left side, in patients with diabetes with and without CAN and controls, respectively,  $p < 0.05$  for comparisons between subjects with diabetes and controls.

**Conclusion:** We may conclude that CVR is impaired in patients with long-term type 1 diabetes mellitus and these disturbances could contribute to the pathogenesis of cerebrovascular disorders in subjects with diabetes. However, CAN does not seem to play a role in the disturbances of CVR in these patients.

1174

### Na<sup>+</sup>/H<sup>+</sup>-exchanger-1 contributes to diabetic peripheral neuropathy through methylglyoxal-derived AGE formation and oxidative-nitrative stress

A.A. Obrosova<sup>1</sup>, S. Lupachyk<sup>1</sup>, P. Watcho<sup>1</sup>, H. Shevalye<sup>1</sup>, V.M. Monnier<sup>2</sup>, I.G. Obrosova<sup>1</sup>;

<sup>1</sup>Pennington Biomedical Research Center, Louisiana State University System, Baton Rouge, <sup>2</sup>Pathology, Case Western Reserve University, Cleveland, USA.

**Background and aims:** Glycolytic enzyme activities strongly depend on intracellular pH which is largely controlled by ubiquitously distributed isoform of Na<sup>+</sup>/H<sup>+</sup>-exchanger, NHE-1. Diabetes and high glucose increase NHE-1 protein content and activity. We hypothesized that NHE-1 plays an important role in diabetic peripheral neuropathy (DPN), and that NHE-1-driven upregulation of glycolysis under conditions of inhibition (endothe-

lial cells) or insufficient activation (Schwann cells) of glyceraldehyde 3-phosphate dehydrogenase leads to the diversion of the excessive glycolytic flux to methylglyoxal and  $\alpha$ -glycerophosphate, formation of methylglyoxal-derived AGE and oxidative-nitrative stress.

**Materials and methods:** In experiment 1, the severities of DPN were compared in STZ-diabetic NHE-1+/- mice (12-wk duration of STZ-diabetes) and the corresponding diabetic wild-types (C57Bl/6J background). In experiment 2, levels of 4-hydroxynonenal adducts, nitrated proteins, methylglyoxal-derived AGE (all by Western blot analyses), as well as pentosidine, carboxymethyl lysine (CML), and furosine (all by GC/MS or LC-MS/MS) were compared in the sciatic nerves of STZ-diabetic rats maintained with or without treatment with the specific NHE-1 inhibitor cariporide (10 mg kg<sup>-1</sup>d<sup>-1</sup>, 4-wk treatment after 12 wks of untreated diabetes). In experiment 3, control and STZ-diabetic rats were treated with lisinopril (1 mgkg<sup>-1</sup>d<sup>-1</sup>) or canrenone (8 mgkg<sup>-1</sup>d<sup>-1</sup>), to evaluate the role for angiotensin 2 and aldosterone in diabetes-induced NHE-1 expression.

**Results:** In contrast to the wild-types, STZ-diabetic NHE-1+/- mice did not develop sensory nerve conduction velocity deficit. They also displayed less severe motor nerve conduction velocity deficit, thermal hypalgesia, tactile allodynia, and intraepidermal nerve fiber loss. Cariporide treatment counteracted diabetes-induced accumulation of 4-hydroxynonenal adducts, nitrated proteins, and methylglyoxal-derived AGE, without affecting pentosidine, CML, or furosine levels in the sciatic nerve. Both lisinopril and canrenone reduced, but did not completely prevent, diabetes-associated increase in NHE-1 immunoreactivity in dorsal root ganglia. The measurements in peripheral nerve and spinal cord are in progress.

**Conclusion:** Angiotensin 2 and aldosterone-mediated NHE-1 upregulation contributes to nerve conduction deficit and small sensory nerve fiber dysfunction and degeneration. The contribution of NHE-1 to diabetic peripheral neuropathy is likely mediated through oxidative-nitrative stress and methylglyoxal-derived AGE formation.

## 1175

### Deep breathing improves blunted baroreflex sensitivity in obese children with insulin resistance

M. Vandoni<sup>1</sup>, V. Calcaterra<sup>2</sup>, G. DeBarbieri<sup>3</sup>, D. Larizza<sup>2</sup>, R. Albertini<sup>2</sup>, A. Brigatti<sup>1</sup>, L. Correale<sup>1</sup>, M. Arpesella<sup>1</sup>, L. Bernardi<sup>3,4</sup>

<sup>1</sup>Department of Public Health, Pavia University, Italy, <sup>2</sup>Department of Internal Medicine-Paediatrics, Pavia University, Italy, <sup>3</sup>Department of Internal Medicine, Pavia University, Italy, <sup>4</sup>Folkhaelsan research Center, University of Helsinki, Finland.

**Background and aims:** Similarly to diabetes, patients with obesity show insulin resistance and autonomic abnormalities associated with increased morbidity and mortality. Although in diabetes autonomic abnormalities are conventionally considered as an organic irreversible disorder, it was previously shown that reduced baroreflex sensitivity (BRS) could be acutely corrected by slow deep breathing, suggesting that these abnormalities could be in part also functional. We then tested whether the autonomic abnormalities in young obese children result from an organic or still functional impairment (thus still reversible with appropriate interventions), and tested whether the extent of possible improvement was associated with the degree of obesity, insulin and insulin resistance.

**Materials and methods:** In 133 obese children (11.5 ± 2.9 years, 68 female 65 male, Body Mass Index (BMI) 26.9±0.4 kg/m<sup>2</sup>, mean±SEM) and 168 age-matched healthy control children, (11.5±2.5 years, 95 female 73 male, BMI 18.8±0.2 kg/m<sup>2</sup>, p<0.001) we measured fasting insulin, glucose and insulin resistance (HOMA-IR), and BRS during spontaneous (in supine and upright position) and supine controlled breathing at normal (15 breath/min) and slow-deep (6 breath/minute) breathing by simultaneous recording of beat-to-beat blood pressure (Portapres<sup>®</sup>) and electrocardiogram.

**Results:** As compared to controls, obese children showed higher systolic blood pressure (109.5±0.9 vs 103.0±1.5 mmHg p<0.001), insulin (13.1±1.1 vs 4.9±0.5 microIU/ml p<0.001) and HOMA-IR (2.52±0.22 vs 0.68±0.09 p<0.001). BRS was reduced in obese children during supine spontaneous breathing (16.3±0.8 vs 18.9±1.0 ms/mmHg, p=0.05) and even more during 15 breath/minute (12.8±0.6 vs 16.5±0.9 ms/mmHg, p=0.0011) and in upright position (8.1±0.3 vs 12.2±0.6 ms/mmHg, p=0.0001). However, during slow breathing the BRS increased markedly in both groups, and in obese children the values were close to those of control children (20.1±0.9 vs 22.7±0.9 ms/mmHg, p=0.053, NS). The extent of the improvement was proportional to the

level of insulin (r=0.24, p=0.0019) and HOMA-IR (r=0.21, p=0.0033), and only to a lower extent with BMI (r=0.13, p=0.034).

**Conclusion:** Despite evident insulin resistance and blunted resting BRS, obese children improve their BRS abnormality in response to slow breathing to an extent proportional to the metabolic abnormality. This suggests that, rather than consequence of neural anatomic lesion, the autonomic involvement is of functional origin, and likely linked to the glucose metabolism abnormalities (hyperinsulinemia and insulin resistance).

## 1176

### Repeated exposure to hypoxia improves respiratory reflexes in type 1 diabetes mellitus

L. Bernardi<sup>1,2</sup>, T. Duennwald<sup>3</sup>, D. Gordin<sup>2</sup>, A. Sandelin<sup>2</sup>, H. Gatterer<sup>3</sup>, A. Tiitu<sup>2</sup>, C. Fogarty<sup>2</sup>, M. Rosengård-Bärlund<sup>2</sup>, C. Forsblom<sup>2</sup>, M. Burtcher<sup>3</sup>, P.-H. Groop<sup>2</sup>, FinnDiane Study Group;

<sup>1</sup>Department of Internal Medicine, Pavia University, Italy, <sup>2</sup>Division of Nephrology, Department of Medicine, Helsinki University Central Hospital, University of Helsinki, Finland, <sup>3</sup>Department of Sports Science, Innsbruck University, Austria.

**Background and aims:** Intermittent hypoxic training (IHT), a technique involving exposure to 5-6 short periods (5-10min) intermittent hypoxia each day over 1-3 weeks, has successfully been used to improve adaptation to hypoxia in healthy subjects and patients with chronic bronchitis by stimulating ventilatory reflexes. In diabetes, respiratory reflexes and adaptation to hypoxia are known to be reduced. We therefore tested whether repeated hypoxic exposures over 1 day could initiate a long-lasting response that could potentially lead to better adaptation to hypoxia.

**Materials and methods:** In 15 patients with type 1 diabetes (age 36.5±1.2 yrs, [mean± SEM], diabetes duration 8.1±0.3 yrs, HbA1c 8.0±0.3 %, 13 males 2 females) we measured hypoxic and hypercapnic ventilatory responses as well as ventilatory recruitment threshold, (VRT-CO<sub>2</sub>), after 0, 3 and 6 hours of a 1-hour single bout of IHT (6-minute breathing of a 13% oxygen mixture 5 times, each time separated by a 6-minute recovery phase). The measurements were repeated on a placebo day (at least 1 week apart) in which subjects were only breathing room air (single blind protocol). The sequence of the placebo and intervention day was randomised.

**Results:** Immediately after IHT, the hypoxic and hypercapnic ventilatory responses increased from 0.23±0.04 to 0.36±0.07 L/min/%SaO<sub>2</sub> (paired t-test p<0.05), and from 0.22±0.06 to 0.39±0.107 L/min/mmHg-CO<sub>2</sub> (p<0.05), respectively, whereas the VRT-CO<sub>2</sub> dropped from 44.1±1.2 to 42.0±0.8 mmHg (p<0.05). The same directional changes remained significant after 3 hours for the hypoxic, and after 6 hours for the hypercapnic ventilatory responses. No such changes were observed during the placebo day.

**Conclusion:** In patients with type 1 diabetes repeated exposures to hypoxia during one hour induced an initial adaptation to hypoxia with improvement in the respiratory reflexes. It may be that patients with type 1 diabetes could benefit from a full (>2 weeks) IHT training.

### Comparison of efficacy and safety of once-daily dosing and on-demand use of udenafil for type 2 diabetes patients with erectile dysfunction

K.-S. Park<sup>1</sup>, S. Park<sup>1</sup>, J. Lee<sup>1</sup>, B. Cha<sup>2</sup>, S. Park<sup>3</sup>, K. Min<sup>4</sup>, Y. Sung<sup>5</sup>, T. Kim<sup>6</sup>, I. Park<sup>7</sup>, H. Moon<sup>1</sup>

<sup>1</sup>Endocrinology & Metabolism, Department of Internal Medicine, Eulji University Hospital, Daejeon, <sup>2</sup>Endocrinology & Metabolism, Department of Internal Medicine, College of Medicine the Catholic University of Korea, Seoul, <sup>3</sup>Endocrinology & Metabolism, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, <sup>4</sup>Endocrinology & Metabolism, Department of Internal Medicine, Eulji General Hospital, Seoul, <sup>5</sup>Endocrinology & Metabolism, Department of Internal Medicine, Ewha Woman's University School of Medicine, Seoul, <sup>6</sup>Endocrinology & Metabolism, Department of Internal Medicine, College of Medicine, Hanyang University, Seoul, <sup>7</sup>Endocrinology & Metabolism, Department of Internal Medicine, Gachon University of Medicine and Science Graduate School of Medicine, Incheon, Republic of Korea.

**Background and aims:** We compared the efficacy and safety between once-daily dosing and on-demand use of udenafil for type 2 diabetes patients with erectile dysfunction.

**Materials and methods:** A multi-center, randomized, open-label, parallel group, 12-week study was conducted. Patients who have shown improvement with on-demand 200mg udenafil according to Sexual Encounter Profile (SEP) diary Q2, Q3 were randomized into 200mg on-demand (n=80) or 50mg once-daily (n=81) for 8 weeks and 4 weeks of treatment-free period was followed. Udenafil was controlled in order to match the same total dose in both groups. The primary efficacy endpoint was the change of the International Index of Erectile Function (IIEF) erectile function domain (EFD) score. Secondary efficacy endpoints included changes of the SEP diary Q2, Q3, IIEF Q3, Q4, other domains of IIEF, the Global Assessment Questionnaire (GAQ), shift to normal rate (EFD $\geq$ 26). Vascular endothelial markers were assessed at baseline and after 8 weeks of treatment.

**Results:** Both groups showed significant improvement in IIEF-EFD score after 8 weeks of treatment compared to the score at screening visit ( $p<0.0001$ ). There was no significant difference between two groups. And the effect was not maintained during the treatment-free follow-up period. Similar results were observed in secondary efficacy end points. There was also no significant difference in vascular endothelial markers. Daily udenafil was well tolerated and showed non-significant tendency for fewer adverse drug reactions and adverse events.

**Conclusion:** Both methods of medication improved erectile dysfunction in diabetes patients without significant difference. Daily udenafil was not only well tolerated but also not inferior to on-demand udenafil.

**Effects of diabetes and peripheral neuropathy on joint torque development and muscle activation characteristics during stair descent**  
J.C. Handsaker<sup>1</sup>, A.J.M. Boulton<sup>2</sup>, S.J. Brown<sup>1</sup>, C.N. Maganaris<sup>1</sup>, G. Cooper<sup>3</sup>, F.L. Bowling<sup>2</sup>, N.D. Reeves<sup>1</sup>;

<sup>1</sup>IRM, Manchester Metropolitan University, <sup>2</sup>University of Manchester, <sup>3</sup>Manchester Metropolitan University, UK.

**Background and aims:** Diabetic Peripheral Neuropathy (DPN) has been shown to result in altered gait characteristics on level ground, ensuing from a decreased joint range of motion and muscular strength. An adequate rate of joint torque development and co-ordinated muscular recruitment patterns are key to a safe and stable gait cycle, particularly during the potentially dangerous task of stair descent. However, due to the lack of plantar sensitivity, it is hypothesised that DPN patients will not be able to detect key gait events to trigger these mechanisms sufficiently. This study examines the effects of diabetes and DPN on joint torque development and muscle activation characteristics during stair descent.

**Materials and methods:** 21 participants: 7 with DPN, 7 with diabetes but no/mild neuropathy (D), and 7 matched-controls descended an instrumented staircase. Three-dimensional movement, force and electromyographic (EMG) data were obtained. Values for knee and ankle joint torque generation were calculated between step contact and the peak joint moment. EMG activity was measured from a representative knee extensor (vastus lateralis), and plantar flexor (gastrocnemius) muscle, and processed in MatLab using a bespoke program to identify muscle on/off timings. Group differences were tested statistically using an analysis of variance and post-hoc tests.

**Results:** With reference to foot-step contact (FSC), the gastrocnemius muscle was activated much earlier by the D and particularly DPN groups (DPN: -202, D: -114, and Control: -61 ms;  $P=0.02$ ). In contrast, the vastus lateralis muscle was activated later and closer to the FSC by the D and DPN groups than the controls (DPN: -29, D: -39 and control: -62 ms;  $P>0.05$ ). Similar values for the rate of joint torque development were observed between groups, at the ankle (DPN: 5.2, D: 6.7 and Control: 5.8 Nm.kg.s<sup>-1</sup>;  $P>0.05$ ). In contrast, the rate of torque development at the knee showed a borderline significant difference between the groups (DPN: 6.34, D: 5.8 and Control: 7.3 Nm.kg.s<sup>-1</sup>;  $P=0.08$ ), with a slower rate of joint torque development seen in the two diabetic groups. An earlier pre-activation of the plantar flexor muscles responsible for controlling dorsiflexion of the foot upon FSC by the diabetic groups enabled generation of a similar rate of torque development to that of controls. In contrast, the delayed pre-activation of the knee extensor muscles responsible for controlling knee flexion upon FSC in the diabetic groups lead to a trend for a slower rate of torque development at the knee compared to controls.

**Conclusion:** People with diabetes, and to a greater degree those with DPN, displayed a strategy to compensate for the lack of plantar sensitivity by activating the plantarflexor muscles earlier in anticipation of FSC. In contrast, activation of the knee extensors in diabetics and DPN patients before FSC was delayed relative to controls and may reflect prioritization of the ankle plantar flexors for 'absorbing' the initial energy associated with stepping down. These differences in muscle activation and rate of joint torque development have implications for dynamic balance and the risk of falls in people with diabetes.

## 1179

**Gabapentin/vitamins B1/B12: an efficacious and safe combination for painful diabetic peripheral neuropathy control**

M. Alpizar<sup>1</sup>, A.J. Mimenza<sup>2</sup>, R.A. Olivares<sup>3</sup>, G. Villalpando<sup>4</sup>, S.G. Aguilar<sup>2</sup>, A. Aguilar<sup>5</sup>, A.G. Garcia<sup>5</sup>, A. Torres<sup>5</sup>;

<sup>1</sup>CEDOPEC, <sup>2</sup>INNSZ, <sup>3</sup>ARKE, <sup>4</sup>CRI, <sup>5</sup>Merck, Mexico City, Mexico.

**Background and aims:** B vitamins roll in the treatment of diabetic neuropathy (DNP) is due in their effect over multiple pathways secondary to hyperglycaemia, like oxidative stress (protein kinase-C, diacylglycerol, and hexosamine pathways); likewise, to their action over nitric oxide, that explains their antihyperalgesic, antialodinic, and antinociceptive effects. The combination of thiamine and cyanocobalamin with gabapentin provide a synergistic effect, that allows a better tolerability to gabapentin, and a better analgesic effect. The main objective of this trial was to compare the efficacy for pain relief, and the safety profile of two oral medications gabapentin/vitamins B1/B12 fixed combination (GVB) vs. pregabalin (pregaba), in mild to moderate DPN, during a three months period.

**Materials and methods:** The multicentre clinical trial designed was open, randomized, and comparative, with parallel groups. Patients were followed during 12 weeks. Efficacy evaluations were performed by a numeric pain intensity scale, visual analogue scale (VAS) and Leeds Assessment of Neuropathic Symptoms and Signs (LANSS) scale. Safety assessment was carried out through adverse events (AE).

**Results:** 323 subjects who signed an informed consent were enrolled into the study. 291 patients integrated the Intent-To-Treat (ITT) population and 239 patients the Per-Protocol (PP) population. 52% of patients received GVB, and 48% received pregaba. Numeric pain intensity scale was measured in every visit. A multivariate repeated measurements analysis was performed and every mean value during follow-up differed from baseline values, for both treatments ( $p < 0.001$ ), with no difference between treatments ( $p = 0.562$ ). Pain decrease profile was similar for both treatments. About LANSS scale, again every mean value was different from baseline measurement for both treatments ( $p < 0.001$ ), with no difference between groups ( $p = 0.730$ ). Dose scheme was titrated-up until maximum dose was reached, or to the highest dose that was tolerated. For GVB, pain relief started with the minimum dose (900 mg/day), with practically no change compared up to maximum dose (3,600 mg/day). For pregaba, there were no statistical differences among doses, which were similar from 150 to 600 mg/day. Safety was evaluated through AE evaluation. There were 291 patients who reported at least one adverse event during study. For GVB group, 65/146 patients (44.52%) presented at least one adverse event. For pregaba group, figures were 76/145 and 52.41%, respectively.

**Conclusion:** Due to the difficulty of pain handling, clinical research on neuropathic pain control is wide, including multiple therapeutic alternatives. Clinical results on pain intensity scale demonstrate that GVB is as good as

pregaba, which constitutes the standard first choice for the management of neuropathic pain in multiple guidelines. Different measurement scales were used to evaluate pain evolution, and data point out that neuropathic pain significantly decreased from a baseline score of 6.5 mm to 2.5 mm ( $p < 0.001$ ) at the end of treatment period in both treatments ( $p = 0.562$ ). Our clinical study demonstrate that GVB and pregaba have a similar safety and efficacy profile; although there was no statistically significant difference, a greater trend towards adverse events in pregaba group was observed.

### Nondipping is a novel associated disorder of painful diabetic polyneuropathy

V. Spallone<sup>1</sup>, R. Morganti<sup>1</sup>, C. D'Amato<sup>1</sup>, C. Greco<sup>1</sup>, F. Di Gennaro<sup>1</sup>, L. Cacciotti<sup>1</sup>, G.A. Marfia<sup>2</sup>;

<sup>1</sup>Endocrinology, Department of Internal Medicine, <sup>2</sup>Neurology, Department of Neurological Sciences, Tor Vergata University, Rome, Italy.

**Background and aims:** Sleep problems are common in painful diabetic polyneuropathy (PDPN) and the loss of the nocturnal fall in blood pressure (BP) is a recognized feature of diabetic autonomic neuropathy. We evaluated the relationship of BP circadian pattern with neuropathic pain and pain-related sleep disturbance in PDPN.

**Materials and methods:** In 105 patients with diabetes (age  $58.3 \pm 11.1$  years, diabetes duration  $15.8 \pm 12.2$  years, BMI  $29.4 \pm 4.6$  Kg/m<sup>2</sup>, 71 male, 22 with type 1 diabetes), among which 35 with PDPN (PDPN), 31 with non painful diabetic polyneuropathy (DPN<sup>+</sup>) and 39 without DPN (DPN<sup>-</sup>), neuropathic pain, sleep characteristics, risk for obstructive sleep apnoea (OSA), cardiovascular autonomic function, and BP circadian pattern were assessed using Douleur Neuropathique en 4 Questions (DN4), Brief Pain Inventory (BPI), MOS Sleep Scale (MOS-SS), Berlin Questionnaire (BQ), 4 cardiovascular autonomic reflex tests (CARTs), and 24-hour ambulatory BP monitoring (ABPM).

**Results:** PDPN group showed worse scores of MOS-SS (particularly in the items of 'sleep adequacy' and 'awaken short of breath or with headache'), and higher MOS-SS 9-item Sleep Problem Index ( $40.0 \pm 22.3$ ) compared to both DPN<sup>-</sup> group ( $22.3 \pm 17.7$ ,  $P = 0.0004$ ) and DPN<sup>+</sup> group ( $26.4 \pm 21.7$ ,  $P = 0.0155$ ). Moreover, PDPN group displayed higher night systolic BP ( $128.6 \pm 16.3$  Vs  $119.9 \pm 11.3$  mmHg,  $P = 0.009$ ) and lower day-night difference ( $\Delta$ ) in systolic BP than DPN<sup>-</sup> group ( $5.9 \pm 7.2$  Vs  $9.2 \pm 6.1$ ,  $P = 0.039$ ). No significant differences were found, instead, between DPN<sup>+</sup> group and DPN<sup>-</sup> group for MOS-SS and ABPM results, nor between PDPN group and DPN<sup>+</sup> group for CART results. The condition of non-dipping ( $\Delta$  systolic BP  $\leq 0\%$ ) was associated with PDPN ( $\text{Chi}^2 = 6.7$ ,  $P = 0.01$ ), higher CART score ( $2.9 \pm 2.9$  Vs  $1.3 \pm 1.9$ ,  $P = 0.019$ ), higher DN4-Interview score ( $4.0 \pm 2.7$  Vs  $1.7 \pm 1.7$ ,  $P = 0.0004$ ), and in PDPN patients with higher BPI pain now intensity score ( $7.2 \pm 3.6$  Vs  $2.3 \pm 2.8$ ,  $P = 0.0006$ ). The presence of high risk of OSA (i.e. 2 positive BQ categories) was not associated with PDPN, but with lower  $\Delta$  systolic BP ( $6.1 \pm 6.2$  Vs  $9.2 \pm 6.3$ ,  $P = 0.017$ ), higher MOS-SS 9-item Sleep Problem Index ( $38.9 \pm 21.9$  Vs  $23.7 \pm 19.7$ ,  $P = 0.0004$ ), and in PDPN patients with both higher pain severity score ( $6.6 \pm 2.2$  Vs  $3.6 \pm 2.4$ ,  $P = 0.0009$ ) and higher BPI pain intensity index ( $5.6 \pm 2.5$  Vs  $3.1 \pm 2.3$ ,  $P = 0.008$ ). In a stepwise regression analysis including as independent variables age, male sex, diabetes duration, BMI, orthostatic hypotension, DN4-Interview score, high risk of OSA, and MOS-SS Sleep Problem Index,  $\Delta$  systolic BP was independently related to orthostatic hypotension (step 1), DN4-Interview score (step 2), and high risk of OSA (step 3) ( $r = 0.46$ ,  $P = 0.0002$ ).

**Conclusion:** Non-dipping is a new associated disorder of PDPN and neuropathic pain is an independent determinant of BP circadian pattern. Although the pathogenetic meaning of this complex relationship remains incompletely clarified, PDPN should increasingly be regarded as a condition of high cardiovascular risk.

## 1181

### A biopsychosocial examination of factors contributing to sleep impairment in painful diabetic neuropathy

L. Thomas, D. Selvarajah, T. Cash, R. Gandhi, A. Sankar, J. Davies, S. Tesfaye; Diabetes Research Unit, University of Sheffield, UK.

**Background and aims:** Sleep is an important component of good general health and well being. It is also well recognised that sleep disturbance in painful diabetic neuropathy (DN) is common and leads to substantial impairments in quality of life. However, our current knowledge regarding the relationship between sleep, mood disorders and physical functioning in painful DN is limited. The aim of this study was thus to assess the contributions of the diabetes state, neuropathic pain and psychological factors to self-reported sleep disturbance in patients with painful DN.

**Materials and methods:** 113 patients with confirmed painful DN participated in a burden of illness assessment study. This study adopted a multidimensional approach to test a biopsychosocial model to understanding sleep disturbance in painful DN. Each patient underwent structured interviews, detailed clinical assessments and completed self-reported measures of pain severity (Brief Pain Inventory DN [BPI-DN]), pain acceptance (Chronic Pain Acceptance [PCA] questionnaire), illness beliefs (Pain Catastrophizing Scale [PCS]), affective distress (Hospital Anxiety and Depression [HADS] questionnaire) and sleep impairment (Medical Outcomes Study-Sleep [MOS-Sleep] Scale). In addition, patients provided information regarding their age, gender, marital status, social deprivation score, medication use, diabetes and other medical co-morbidities.

**Results:** 108 patients (96%) reported moderate to severe levels of sleep impairment which affected all subscales of the MOS-sleep questionnaire (sleep disturbance, adequacy quality and somnolence). A set of predictor variables was established using bivariate correlation analyses. Female gender ( $p = 0.005$ ), pain severity (BPI-DN  $p < 0.001$ ), affective distress (HADS-Anxiety and HADS-Depression  $p < 0.001$ ) and illness beliefs (PCS  $p < 0.001$ ) were all correlated positively with MOS-Sleep score, while age ( $p = 0.001$ ), pain acceptance (PCA  $p < 0.001$ ) and diabetic comorbidities ( $p = 0.002$ ) were correlated negatively with MOS-Sleep. SNRIs ( $p = 0.01$ ), anticonvulsants ( $p = 0.04$ ) and opiates (0.01) but not tricyclic antidepressants ( $p = 0.32$ ) use were correlated with greater sleep impairment. No significant correlation with marital status, deprivation score and duration of pain or diabetes. Hierarchical multiple regression confirmed that higher anxiety symptom scores ( $\beta = 1.02$ ), greater pain severity ( $\beta = 1.86$ ), less pain acceptance ( $\beta = -0.34$ ) and female gender ( $\beta = 6.30$ ) contributed independently to higher sleep disturbance. This final regression model taking accounted for 57.0% of the variance in MOS-Sleep scores ( $F = 8.65$ ,  $p < 0.001$ ).

**Conclusion:** A very high prevalence of sleep disturbance was found study in this patient population of patients with painful DN. Women were also found to be more susceptible to sleep disturbance. Finally, this study has identified key factors that contribute to sleep disturbance in painful DN and this has implications for the development of rational, empirically based pain management strategies to improve sleep disturbance. Studies are now required to explore the impact of interventions that target pain and anxiety symptoms on sleep outcomes in painful DN.

## 1182

### Serotonin pain facilitation through 5-HT<sub>3</sub> receptor in diabetic neuropathic pain

M.A. Silva, I. Tavares, C. Morgado; Faculty of Medicine of Porto and IBMC, Department of Experimental Biology, University of Porto, Portugal.

**Background and aims:** Diabetic neuropathic pain (DNP) is a chronic and debilitating pain condition that affects about one fifth of diabetic patients. DNP is poorly responsive to the pain killers currently used to treat chronic pain and is only moderately relieved by the use of anticonvulsants and antidepressants. Serotonin selective reuptake inhibitors (SSRIs) were shown to elicit low analgesic effects in DNP, which is difficult to explain considering the pain inhibitory actions of serotonin at the spinal cord in normal conditions. This finding suggests that during DNP the pain modulatory effects of serotonin are likely to be impaired. In acute pain conditions, serotonin inhibits pain transmission by binding to the 5-HT receptors present at spinal dorsal horn, but, it was recently shown, that in a chronic pain situation serotonin may facilitate pain through its action on spinal 5-HT<sub>3</sub> receptor. This mechanism is likely to account to DNP and may explain the low antinociceptive effect of

the SSRIs. Thereafter, this study aimed to evaluate the role of spinal 5-HT<sub>3</sub> receptor (5-HT<sub>3</sub>R) in mediating diabetic-induced mechanical hypersensitivity. **Materials and methods:** Male wistar rats were rendered diabetic by an intraperitoneal injection of streptozotocin (STZ, 60 mg/kg body weight) and the control (CTR) animals received only the vehicle. Three weeks post-injection a catheter was implanted in the lumbar subarachnoid space and animals were allowed to recover for a week. At 4 weeks post-injection mechanical nociception was behaviourally evaluated using the paw pressure test (Randall-Selitto test) in STZ and control rats receiving intrathecal infusions of saline or 5-HT<sub>3</sub> receptor antagonist (30 fmol, Y-25130 hydrochloride).

**Results:** STZ rats presented significantly increased glycaemia (STZ: 520 ± 58 mg/dl; CTR: 127 ± 17 mg/dl,  $p < 0.0001$ ; independent sample t test) and haemoglobin A1C (STZ: 12.0 ± 0.8; CTR: 4.9 ± 0.2,  $p < 0.0001$ ; independent sample t test), along with decreased paw pressure thresholds (STZ: 89 ± 6 g; CTR: 140 ± 1 g,  $p = 0.0006$ ; independent sample t test). The intrathecal delivery of 5-HT<sub>3</sub>R antagonist induced a significant increase in the paw pressure thresholds in the STZ rats whereas no effects were detected in the control rats (Untreated STZ\*: 89 ± 6 g; STZ+Y-25130: 139 ± 7 g; Untreated CTR: 140 ± 1 g; CTR+Y-25130: 139 ± 6 g; \* $p < 0.01$  vs all other groups, One-Way ANOVA followed by tukey post hoc test). The intrathecal infusion of saline did not change the pain behaviour in any experimental group.

**Conclusion:** These results demonstrated that 5-HT<sub>3</sub> receptor activation facilitate the spinal pain transmission in DNP. The increased serotonin level at the synaptic cleft induced by SSRIs administration may elicit pro-nociceptive effects through the activation of 5-HT<sub>3</sub> receptor that may be masking the inhibitory actions of the others spinal 5-HT receptors. New serotonin-based pain therapies for DNP should consider the particular pain facilitating role of 5-HT<sub>3</sub>R.

## PS 103 Diabetic foot: risk factors

### 1183

#### Toe-brachial index is a better index for establishing the severity of PAD than ankle-brachial index in patients with diabetes mellitus

X. He, Z. Huang, A. Chen, Y. Li;

The department of Endocrinology, The first affiliated hospital of Sun Yat-sen University, Guangzhou, Guangdong Province, China.

**Aims:** Ankle-brachial index (ABI) is a useful clinical test for establishing the severity of peripheral arterial disease (PAD). However, there are limitations to this method when conducted on people with diabetes mellitus because of the presence of medial artery calcification. As an alternative to the ankle brachial index, toe-brachial index (TBI) has been recommended to assess the arterial blood supply to the foot. This study evaluated the relevance of ABI and TBI in patients with diabetes, and aimed to obtain more information about when toe-brachial index should be assessed on patients with diabetes mellitus.

**Methods:** 127 subjects with diabetes underwent ABI, TBI (measured by Doppler ultrasound) and low extremity arterial duplex ultrasound (as golden standards) from August 2011 to February 2012. Kruskal-Wallis, one-way analysis of variance was used to compare demographic and clinical parameters of subjects stratified by ABI. Pearson's correlation coefficient was used to assess the linear relationship between two indexes. Receiver operating characteristic (ROC) curve analysis was used to evaluate the sensitivity and specificity of TBI in patients with ABI ≥ 1.3.

**Results:** Of 127 total patients with diabetes, 62.2% had PAD. All patients were categorized into three groups: reduced (ABI ≤ 0.9), normal (0.9 < ABI < 1.3), and elevated (ABI ≥ 1.3). There were no significant differences in demographic and clinical parameters across those three groups. By linear correlation, TBI showed a significant positive correlation with ABI in subjects with an ABI < 1.3. In contrast ( $r = 0.449$ ,  $P = 0.003$ ). In contrast, TBI was not correlated with ABI in patients with an ABI ≥ 1.3. When patients are categorized according to ABI and TBI, there is also good agreement between the tests when ABI is reduced or normal (64.3%), but not when ABI is elevated (24.7%). In patients with ABI ≥ 1.3, ROC analysis showed that sensitivity and specificity of TBI < 0.6 were 76.2% (95%CI, 69.2 to 84.1%) and 88.4% (95%CI, 83.7 to 94.2%).

**Conclusion:** For those patients with high ABI (≥ 1.3), which means overt medial artery calcification, TBI is a better clinical test for establishing the severity of PAD than ABI.

#### The role and the potential ways by which psychological stress impedes diabetic foot ulcer healing

L. Vileikyte<sup>1</sup>, L. Campbell<sup>2</sup>, B. Jiun-Shen<sup>3</sup>, A. Boulton<sup>1</sup>, M. Hardman<sup>2</sup>;

<sup>1</sup>Medicine, University of Manchester, UK, <sup>2</sup>Life Sciences, University of Manchester, UK, <sup>3</sup>Psychology, Ohio University, Columbus, USA.

**Background and aims:** Research indicates that psychological stress (PS)-induced immunomodulation delays acute wound repair. Here we explored the potential role of PS in the more complex diabetic foot ulcer (DFU)-healing paradigm.

**Materials and methods:** Ninety three type 2 DM patients (84% male; mean age 57yrs) with plantar DFU (University of Texas Classification: 69% grade 1A; 11% 1B; 16% 2A; and 4% 2B) completed baseline self-report measures of generalized (Perceived Stress Scale, PSS; Hospital Anxiety and Depression Scale, HADS; and State-Trait Anger Expression Inventory, STAXI) and DFU-specific PS (NeuroQoL-Interpersonal Burden (NeuroQoL-IP) and Patient Interpretation of Neuropathy (PIN) Scales: PIN-Amputation Worry and PIN-Anger at Docs). DFU-specific biomarkers (IL-6, IL-1β, MMP-2 and MMP-9) were determined via quantification of immunohistochemical tissue localization and/or normalized biopsy gene expression. Systemic biomarkers (IL-6 and IL-1β) were measured from patient serum via ELISA.

**Results:** Bivariate analyses revealed multiple measures of increased generalized and DFU-specific emotional distress were associated with: a) decreased local IL-1β at baseline: HADS-Depression ( $r = -0.27$ ;  $p < 0.001$ ) and NeuroQoL-IP ( $r = -0.38$ ;  $p < 0.01$ ); b) decreased MMP-9: HADS-Depression ( $r = -0.29$ ;  $p < 0.05$ ); PIN-Worry ( $r = -0.34$ ;  $p < 0.05$ ) and PIN-Anger ( $r = -0.37$ ;  $p < 0.01$ ); c) increased MMP-2: PIN-Worry ( $r = 0.32$ ;  $p < 0.05$ ) and PIN-Anger ( $r = 0.31$ ;  $p < 0.05$ ). STAXI was associated with higher levels of baseline systemic IL-6 ( $r = 0.32$ ;  $p < 0.01$ ). Intriguingly, greater than 80% DFU area reduction at 6

weeks was less likely in patients reporting more severe PIN-Worry ( $r=-0.36$ ;  $p<0.01$ ) and PIN-Anger ( $r=-0.30$ ;  $p<0.01$ ) and associated with higher baseline levels of systemic IL-6 ( $r=-0.29$ ;  $p<0.05$ ) and local MMP-2 ( $r=-0.32$ ;  $p<0.05$ ).

**Conclusion:** These preliminary data identify potential psychological stress-induced biomarkers linking stress to DFU chronicity.

### Leg ulcers predictors in patients with necrobiosis lipidica and diabetes mellitus type 1

D.A. Semenova<sup>1</sup>, S.A. Prokofev<sup>2</sup>, E.A. Repina<sup>2</sup>, A.U. Tokmakova<sup>1</sup>, S.M. Stepanova<sup>2</sup>, E.V. Matushevskaya<sup>3</sup>, O.N. Bondarenko<sup>1</sup>, U.U. Orlov<sup>4</sup>; <sup>1</sup>Department of Podiatric Medicine and Surgery, Endocrinological Research Centre, <sup>2</sup>Laboratory of Immunology and Genetics, Endocrinological Research Centre, <sup>3</sup>Postgraduate Education, Federal Medicobiologic Agency, <sup>4</sup>Department of Ultrasound, Endocrinological Research Centre, Moscow, Russian Federation.

**Background and aims:** Necrobiosis lipidica (NL) is a chronic inflammatory skin disease with unknown aetiology. The aim of this study was to investigate new diagnostic methods and prognostic factors of leg ulceration in patients with necrobiosis lipidica and diabetes mellitus type 1.

**Materials and methods:** 36 patients with diabetes mellitus type 1 were examined. They were divided into the following two groups: patients with diabetes mellitus type 1 and necrobiosis lipidica (group 1), patients with diabetes mellitus type 1 without necrobiosis lipidica (group 2). The expression of Toll-like receptor type 2 and Toll-like receptor type 3 on monocytes and neutrophils was determined by flow cytometry using monoclonal antibodies. Results were compared with the data of ultrasound skin morphometry and clinical characteristics of the patients.

**Results:** There were 3 males and 21 females in group 1; 2 males and 10 females in group 2. Median age, diabetes mellitus duration, HbA<sub>1c</sub> in group 1 and group 2 were respectively 26 years, 14 years, 9.4 % and 28 years, 15 years, 9.0 %. Intensities of microvascular complications (diabetic retinopathy and diabetic nephropathy) were comparable among the 2 groups. 29% of patients with necrobiosis lipidica had documented chronic ulcers in dermatosis foci. The median duration of chronic wound existence was 5 month [3; 7]. Median thickness of derma in necrobiosis lipidica foci according to ultrasound skin morphometry was 17mm [16;18], median thickness of derma in symmetrical zones of visibly normal skin was 14mm [13; 16]. Derma in necrobiosis lipidica foci was significantly thicker than in normal skin ( $p=0.03$ ). Lower echogenicity and vague border between derma and subcutaneous fat were present in necrobiosis lipidica foci, which may be caused by granulomatous inflammation, destruction of dermal fibres, necrobiosis of connective tissue. It was found that Toll-like receptor type 2 expression on monocytes and fluorescence intensity were significantly decreased in group 1 (59/59) in comparison with group 2 (79/71) ( $p=0.026$  and  $p=0.019$ ). These markers had significant negative correlation with ulceration in patients with necrobiosis lipidica ( $R=-0.84$   $p=0.05$  and  $R=-0.7$ ,  $p=0.046$ ) and thickness of derma measured by ultrasound ( $R=-0.83$ ,  $p=0.003$ ). Toll-like receptor type 3 expression on neutrophils (%) and fluorescence intensity also were significantly lower in group 1 (33/49) in comparison with group 2 (62/53) ( $p=0.04$  и  $p=0.02$ ).

**Conclusion:** Evaluation of the expression of Toll-like receptor type 2 on monocytes and Toll-like receptor type 3 on neutrophils can be used for necrobiosis lipidica risk stratification, predicting disease severity and improving management strategy in patients with diabetes mellitus type 1.

## 1186

### Percutaneous recanalisation in diabetics with critical limb ischaemia: comparison of angiographic and clinical results according to three different classification systems

E. Iacopi<sup>1</sup>, I. Bargellini<sup>2</sup>, A. Coppelli<sup>1</sup>, R. Cervelli<sup>2</sup>, L. Rizzo<sup>1</sup>, R. Cioni<sup>2</sup>, A. Piaggini<sup>1</sup>;

<sup>1</sup>Diabetic Foot Section - Department of Medicine, University of Pisa,

<sup>2</sup>Interventional Radiology Section - Radiology Department, University of Pisa, Italy.

**Background and aims:** To evaluate the ability of three different angiographic classifications of describing the actual pattern of diabetic macro-angiopathy

(DMA) and to test their prognostic value towards clinical outcomes of diabetic foot (DF) patients with critical limb ischaemia (CLI).

**Materials and methods:** We traced back all DF patients with CLI submitted to percutaneous transluminal angioplasty (PTA) in the Section of Interventional Radiology of our Hospital in the years 2009 - 2010. DF lesions were classified according to the Texas University Score System (TUSS). DMA severity was assessed according to three different classification systems based on angiographic pattern: the *Trans Atlantic Society Consensus II* (TASC II), the *Joint Vascular Society Council* (JVSC), and the morphological classification. We eventually correlated the clinical results (healing rate, healing time, rate and level of amputations), with the severity of vascular involvement before and after the revascularization procedures as expressed by the three different classifications.

**Results:** We evaluated 202 consecutive PTA performed in 166 diabetic patients (Male/female 115/51, mean age 72.8±9.8 yrs, duration of diabetes 20.5±12.1 yrs, HbA<sub>1c</sub> 7.8±1.8%). 43.6% of FL were scored as D3 according to TUSS and involved the forefoot in 78.7% of the cases. TASC II was not applicable in 55.4% of patients before and in no patient after PTA because of the absence of supra-popliteal arterial stenosis. The mean score assigned with JVSC was 7.8±1.7 before and 4.8±2.3 ( $p<0.01$ ) after PTA while according to the Graziani classification we observed a pre-procedural mean score of 4.8±0.9 and a post-procedural one of 1.4±0.5 ( $p<0.01$ ). The immediate technical success rate of PTAs was 93.6%. Patients were followed up for 13.4±9.7 months. The complete healing of lesions was reached by 66.8% of patients with a healing time of 28.4±23.7 weeks, while 3.9% of them needed to undergo a major amputation. Patients healed with a minor amputations were 47%. Among all the clinical and angiographic variables included in the analysis, only JVSC scores were significantly associated to the clinical outcome ( $p=0.04$ ).

**Conclusion:** TASC II is inadequate to describe vascular involvement in the of diabetic patients with CLI. While both the other classifications are effective in describing both basal and post-PTA conditions of DMA, only JVSC is a reliable predictor of outcome in DF patients with CLI.

## 1187

### Risk factors for cardiovascular mortality in patients with diabetic foot ulcers: a longitudinal study

T. Tay<sup>1</sup>, L. Cho<sup>1</sup>, J. Khoo<sup>1</sup>, R. Chen<sup>1</sup>, S. Barbier<sup>2</sup>, J. Ng<sup>1,2</sup>;

<sup>1</sup>Changi General Hospital, Singapore, <sup>2</sup>Duke-NUS, Singapore.

**Background and aims:** Diabetic foot ulcers has a prevalence of 10% per year and is an important cause of morbidity and mortality for patients with diabetes mellitus. The cardiovascular mortality are as high as 44% after 5 years in these patients. There are few studies looking at metabolic parameters which could lead to the increased mortality and cardiovascular morbidity after the onset of diabetic foot ulcers. We aim to evaluate the changes in metabolic parameters that occur after the development of diabetic foot ulcers which may explain why these subjects have a higher risk of cardiovascular mortality.

**Materials and methods:** A longitudinal study of 193 new onset diabetic foot ulcer subjects and 386 type 2 diabetes mellitus matched controls with no foot ulcers attending similar diabetes services at a tertiary regional hospital in Singapore were studied and followed annually for 6 years from January 2004 to March 2010. Their HbA<sub>1c</sub>, lipid profile, urine microalbumin, blood pressure and body mass index (BMI) were monitored yearly.

**Results:** The baseline characteristics of the cases and controls were similar. Glycated hemoglobin (A1c) were similar in cases and controls at 8.2±2% at baseline and 8.0±1.6% at the end of follow-up ( $p=0.53$ ). In contrast, BMI increased steadily and significantly in subjects with new onset foot ulcers over the course of follow-up (Figure 1). The mean percentage increase in BMI after 6 years was 5.5%, compared with controls of 1.4% ( $p=0.01$ ). The mortality rate was significantly higher in subjects with foot ulcers compared with controls after 6 years, despite no difference in trends in A1c, lipid profile and blood pressure (7.3% vs 3.1% respectively,  $p=0.02$ ).

**Conclusion:** Patients are at risk of being overweight and obese after development of diabetic foot ulcers. Early mobilization of patients with diabetic foot ulcers to encourage independence would be an important goal. Controlling BMI, besides optimization of DM, hypertension and hyperlipidemia, is important for reducing cardiovascular morbidity and mortality. Weight neutral treatment such as GLP-1 agonists might play a role in maintaining glycemic control as well as BMI. More follow-up studies would be needed to confirm the outcome of diabetic adults who gain weight after developing foot ulcers.

## 1188

### Vascular, sensory and renal function in patients attending community-based foot screening: results from the West of Ireland Diabetes Foot Study

L. Hurley<sup>1</sup>, A.P. Garrow<sup>2</sup>, L. Kelly<sup>1</sup>, L.G. Glynn<sup>3</sup>, S.F. Dinneen<sup>1,4</sup>;

<sup>1</sup>Diabetes Centre, University Hospital Galway, Ireland, <sup>2</sup>School of

Social Work, Psychology and Public Health, University of Salford, UK,

<sup>3</sup>Department of General Practice, National University of Ireland, Galway,

Ireland, <sup>4</sup>Department of Medicine, National University of Ireland, Galway, Ireland.

**Background and aims:** Annual diabetic foot screening is recommended with subsequent care determined by the patients' assigned risk status. With an increasing emphasis on primary care based diabetes care, general practice is the ideal setting for this screening. This study aimed to describe the prevalence of risk factors for diabetic foot ulceration in Irish General Practice.

**Materials and methods:** All patients with diabetes attending 12 general practices were invited for screening. Examination comprised 10g monofilament cutaneous pressure perception (CPP), vibration perception threshold (VPT) and a composite modified neuropathy disability score (mNDS). Vascular status was assessed by palpation of pedal pulses (PP) and doppler waveform assessment. The most recent creatinine result was used to calculate eGFR [using the abbreviated MDRD equation:  $186 \times (\text{Creat} / 88.4)^{-1.154} \times (\text{Age})^{-0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if black})$ ] and hence chronic kidney disease (CKD) stages.

**Results:** Of the total invited for screening 563 (68%) patients attended. Mean age was 64 years (SD13), 60% were male, 90% had type 2 diabetes and mean duration of diabetes was 7.7 years. Mean HbA<sub>1c</sub> was 7.3% (SD1.4), serum creatinine 89.6μmol/l (SD31.5) and eGFR 78.4ml/min/1.73m<sup>2</sup> (SD24.4). A review of medical records revealed 51% had hypertension, 26% cardiovascular disease, 3.7% reported a prior foot ulcer and 1.6% an amputation. On examination 25% had impaired CPP, 23% impaired VPT and 24% abnormal mNDS. All three modalities were abnormal in 10% of patients. 18% had ≥2 PP absent and 39.6% had abnormal doppler waveform assessment defined as a mono- or biphasic pulse. Those with abnormal CPP, VPT or mNDS had a significantly lower mean eGFR than those with normal sensory function: 74.1 vs 79.9ml/min/1.73m<sup>2</sup> for CPP ( $p=0.02$ ), 68.4 vs 80.2ml/min/1.73m<sup>2</sup> for VPT ( $p<0.001$ ) and 72.2 vs 80.5ml/min/1.73m<sup>2</sup> for mNDS ( $p<0.001$ ). Renal function was also poorer in patients with abnormal PP palpation or doppler waveform compared to those with normal vascular function: eGFR 70.2 vs 80.2ml/min/1.73m<sup>2</sup> ( $p<0.001$ ) and 71.6 vs 82.9ml/min/1.73m<sup>2</sup> ( $p<0.001$ ) respectively. Stage 3 and 4 CKD was prevalent in 19.3% and 2% of patients. There was a stepwise increase in the prevalence of all sensory and vascular risk factors with advancing CKD (Table 1).

**Conclusion:** Our data show the extent of sensory dysfunction and vascular impairment in a representative sample of diabetic patients in general practice and supports existing data showing a relationship between these risk factors and CKD. The use of eGFR may facilitate the identification of at-risk patients earlier in the disease process.

### Prevalence of sensory and vascular risk factors in CDK groups

Table 1	Normal: Stage 1 CKD	Mild: Stage 2 CKD	Moderate/Severe: Stage 3 or 4 CKD	p-value
n(%)				
Abnormal CPP	31/157 (19.7%)	66/238 (27.7%)	35/107 (32.7%)	0.05
mNDS>6	26/157 (16.6%)	59/238 (24.8%)	40/107 (37.4%)	0.001
VPT>25	13/79 (16.5%)	34/151 (22.5%)	25/64 (39.1%)	0.005
Abnormal PP	17/157 (10.8%)	42/238 (17.6%)	31/107 (29.0%)	0.001
Abnormal doppler waveform	45/157 (28.7%)	91/238 (38.2%)	65/107 (60.7%)	<0.001

### Preserved microcirculation in the foot after intensified insulin treatment in patients with type 1 diabetes mellitus

B. Rathsmann<sup>1,2</sup>, T. Nyström<sup>1,3</sup>, K. Jensen-Ustad<sup>1,4</sup>;

<sup>1</sup>Department of Clinical Science and Education, Södersjukhuset, Karolinska Institutet, <sup>2</sup>Sach's Children's Hospital, Södersjukhuset, <sup>3</sup>Section of Internal Medicine, Södersjukhuset, <sup>4</sup>Section of Clinical Physiology, Södersjukhuset, Stockholm, Sweden.

**Aims:** We sought to investigate microvascular function, by using laser doppler flowmetry and iontophoresis, in the foot of patients with type 1 diabetes after intensified conventional insulin treatment (ICT) compared to patients with standard insulin treatment (ST).

**Methods:** Patients previously participating in the Stockholm Diabetes Intervention Study (SDIS) were reinvestigated after  $12.6 \pm 0.5$  years, with a single point iontophoresis, using a laser doppler technique after stimulation with topically applied acetylcholine (2%), nitroprusside (2%), and capsaicin (2%). The microvascular blood flow, for each of the vasoactive substances used, was calculated as a quotient between the maximal blood flow after stimulation and the basal blood flow. The ankle brachial index (ABI) was also measured. In the SDIS, patients were randomized to ICT or ST, for 7.5 years. In the present study, patients were no longer randomized and treatment was decided by routine care.

**Results:** 35 patients (ICT group, 79.5%) and 37 (ST group, 71.2%) were included from the original SDIS study. The mean age was for the ICT group  $30 \pm 8$  and for the ST group  $32 \pm 8$  years ( $P=0.29$ ). 7.5 years after randomization mean HbA<sub>1c</sub> was reduced from  $9.5 \pm 1.3\%$  to  $7.1 \pm 0.6\%$  in the ICT group, and from  $9.4 \pm 1.4\%$  to  $8.3 \pm 0.7\%$  in the ST group,  $P<0.001$ . 12.6 years after randomization mean HbA<sub>1c</sub> was still significantly lower in the ICT group  $7.4 \pm 0.8\%$  vs. the ST group  $8.3 \pm 0.9\%$ ,  $P<0.001$ . ABI did not differ between the groups,  $1.1 \pm 0.1$  (ICT) vs  $1.1 \pm 0.1$  (ST),  $P=0.7$ . Basal microvascular blood flow did not differ between groups, however, stimulated blood flow was attenuated in the ST vs. ICT group regarding; acetylcholine ( $5.3$  vs  $8.1$ ;  $P=0.004$ ), nitroprusside ( $5.6$  vs  $8.1$ ;  $P=0.031$ ), and capsaicin ( $3.4$  vs  $5.0$ ;  $P=0.005$ ). A significant correlation between mean HbA<sub>1c</sub> during the 7.5 years randomized study was demonstrated between acetylcholine ( $r=0.42$ ,  $P<0.05$ ), nitroprusside ( $r=0.26$ ,  $P<0.05$ ) and capsaicin ( $r=0.28$ ,  $P<0.05$ ). However, in multivariate regression analysis adjusted for duration of diabetes, age, blood pressure, BMI, smoking and HbA<sub>1c</sub> (base-line); mean HbA<sub>1c</sub> during the 7.5 years' randomized study was independently associated with an increase in microvascular blood flow after acetylcholine ( $P=0.001$ ), but not for nitroprusside ( $P=0.115$ ), nor for capsaicin ( $P=0.055$ ).

**Conclusion:** Improvement of hyperglycaemia in patients with type 1 diabetes preserves peripheral microcirculation in a long time perspective. This preservation, of endothelial-dependent microvascular blood flow, seems to be due to lowering hyperglycaemia, independent of other classical risk-factors for endothelial-dysfunction.

## 1190

**Effects of biofeedback on plantar pressure distribution in diabetic patients with peripheral neuropathy**

Z. Pataky<sup>1</sup>, D. De León Rodríguez<sup>2</sup>, L. Allet<sup>3,4</sup>, J. Philippe<sup>5</sup>, J.-P. Assal<sup>6</sup>, C.-A. Hauert<sup>2</sup>, A. Golay<sup>1</sup>;

<sup>1</sup>Division of Therapeutic Education for Chronic Diseases, University Hospitals of Geneva, <sup>2</sup>Faculty of Psychology and Educational Sciences, University of Geneva, <sup>3</sup>Health Care Directorate, University Hospitals of Geneva, Switzerland, <sup>4</sup>Department of Physical Therapy, University of Applied Sciences, Geneva, Switzerland, <sup>5</sup>Service of Endocrinology, Diabetes and Nutrition, University Hospitals of Geneva, Switzerland, <sup>6</sup>Foundation for Research and Training in Patient Education, Geneva, Switzerland.

**Background and aims:** Plantar pressure reduction is essential for diabetic foot ulcer healing. Our aim was to evaluate the impact of a new walking strategy learned by biofeedback on plantar pressure distribution under both feet in patients with diabetic peripheral neuropathy.

**Materials and methods:** Terminally augmented biofeedback has been used for foot off-loading training in 21 patients with diabetic peripheral neuropathy. The biofeedback technique was based on a subjective estimation of performance and objective visual feedback following walking sequences. The patient was considered to have learned a new walking strategy as soon as the peak plantar pressure (PPP) under the previously defined at-risk zone was within a range of 40–80% of baseline PPP, in 70% of the totality of steps and during 3 consecutive walking sequences. The PPP was measured by a portable in-shoe foot pressure measurement system (PEDAR<sup>®</sup>) at baseline (T0), directly after learning (T1) and at 10-day retention test (T2). We used ANOVA with Bonferroni post-hoc testing to determine differences between PPP at different phases of the learning procedure and retention tests.

**Results:** The PPP under at-risk zones decreased significantly at T1 ( $165 \pm 9$  kPa,  $p < 0.0001$ ) and T2 ( $167 \pm 11$ ,  $p = 0.001$ ), as compared to T0 ( $242 \pm 12$  kPa) without any increase of the PPP elsewhere. At the contra-lateral foot (not concerned by off-loading), the PPP was slightly higher under the lateral midfoot at T1 ( $68 \pm 8$  kPa,  $p = 0.01$ ) and T2 ( $65 \pm 8$  kPa,  $p = 0.01$ ), as compared to T0 ( $58 \pm 6$  kPa).

**Conclusion:** The foot off-loading by biofeedback lead to a safe and regular plantar pressure distribution without inducing any new “at-risk” area under both feet.

## PS 104 Genes and chronic complications

## 1191

**FoxO1 acetylation is correlated to metabolic control and expression of inflammatory factors in atherosclerotic plaques from subjects with and without diabetes**

M. Federici<sup>1</sup>, M. Cardellini<sup>1</sup>, E. Martelli<sup>2</sup>, V. Casagrande<sup>1</sup>, F. Davato<sup>1</sup>, A. Valentini<sup>1</sup>, O. Porzio<sup>1</sup>, D. Lauro<sup>1</sup>, A. Ippoliti<sup>1</sup>, R. Lauro<sup>1</sup>, R. Menghini<sup>1</sup>;

<sup>1</sup>Dept. of Internal Medicine, <sup>2</sup>University of Tor Vergata, Rome, Italy.

**Background and aims:** Recent evidences suggested that dynamic interactions between monocyte/macrophage and activated endothelium are regulated via FoxO1-dependent transcription of TLR4 and VCAM1, pinpointing FoxO1 as a pivotal element in the onset of atherosclerosis. FoxO1 function is fine tuned through post-translational modifications, particularly lysine acetylation. Transgenic models carrying constitutively deacetylated Foxo1 in mice (FoxO1KR/KR) showed improved hepatic lipid metabolism and decreased macrophage inflammation, but increased atherosclerosis on a LDLR knockout background. Given these paradoxical results, our aim was to investigate the activity of FoxO1 in human atherosclerosis.

**Materials and methods:** In human atherosclerotic carotid plaques biobank (n=100) we have determined mRNA expression of FoxO1, VCAM-1, TLR4, MMP9, TNF-alpha and CCL2 by quantitative real time PCR (qPCR) normalizing to 18S and analysing with the deltadeltaCT method. In protein extracts we have analyzed the levels of VCAM-1, FoxO1, total FoxO1 Lysine acetylation (FoxO1Ac, 7 Lysine residues acetylated) and FoxO1 acetylation mediated specifically by SirT1 on Lysine 241 (FoxO1-SirT1Ac), normalizing to tubulin and FoxO1 levels. mRNA expression levels were normalized using logarithmic transformation.

**Results:** In atherosclerotic plaques we found that FoxO1Ac was positively correlated with the levels of several inflammatory markers, such as VCAM-1 ( $R = 0.53$   $p < 0.0001$ ), TLR4 ( $R = 0.44$   $p = 0.002$ ) and MMP9 ( $R = 0.44$   $p < 0.0001$ ) mRNA expression, whereas FoxO1-SirT1Ac was mildly correlated only with VCAM-1 mRNA ( $R = 0.25$   $p = 0.005$ ) and VCAM-1 protein levels ( $R = 0.22$   $p = 0.008$ ). Moreover, FoxO1 mRNA expression resulted in correlation with VCAM-1 ( $R = 0.73$   $p < 0.001$ ), TLR4 ( $R = 0.78$   $p < 0.001$ ), TNF-alpha ( $R = 0.75$   $p = 0.002$ ), CCL2 ( $R = 0.7$   $p < 0.001$ ) mRNA expression and with the FoxO1Ac levels ( $R = 0.34$ ,  $p = 0.005$ ). Metabolic analysis indicate that FoxO1Ac is correlated with Fasting Plasma Glucose ( $R = 0.23$   $p = 0.039$ ), therefore we divided our samples in 4 groups according to the metabolic status (Normal Glucose Tolerance n=35, Impaired glucose Tolerance n=31, Type 2 Diabetes Mellitus with new diagnosis and no treatment n=18, Type 2 Diabetes Mellitus under treatment=16); by ANOVA statistical analysis, we found that the degree of metabolic status is positively correlated with FoxO1Ac ( $p = 0.002$ ) whereas the FoxO1 mRNA expression is similar in the different groups.

**Conclusion:** Our data suggest that FoxO1 is differently regulated in atherosclerotic tissues. Hyperglycemia and impaired glucose metabolism were correlated with FoxO1 acetylation status, possibly affecting FoxO1 activity. Previous experimental data suggested that FoxO1 can exert both pro- and anti-inflammatory actions in vascular cells depending on its post-translational acetylation status. In this study, we found that Acetylated FoxO1 is associated to systemic hyperglycemia and atherosclerotic plaque inflammatory markers. The degree of FoxO1 acetylation results in more complex inflammatory state. In conclusion, our study suggests that FoxO1 acetylation status is physiologically relevant and may contribute to the progression of atherosclerosis in human subjects.

**Genetic predisposition to dyslipidaemia in an Italian population at risk of type 2 diabetes. The GENFIEV study**

N. Pulizzi<sup>1</sup>, R. Miccoli<sup>1</sup>, C. Bianchi<sup>1</sup>, R. Bonadonna<sup>2</sup>, F. Giorgino<sup>3</sup>, F. Cavalot<sup>4</sup>, G. Cavallo<sup>5</sup>, S. Frontoni<sup>6</sup>, G. Marchesini<sup>7</sup>, L. Groop<sup>8</sup>, S. Del Prato<sup>1</sup>, on behalf of the GENFIEV-FoRiSID Study Group;

<sup>1</sup>Department of Endocrinology and Metabolism, Pisa University, Italy,

<sup>2</sup>Department of Medicine, University of Verona, Italy, <sup>3</sup>Department

of Emergency and Organ Transplantation, University of Bari, Italy,

<sup>4</sup>Department of Clinical Biological Sciences, University of Turin, Italy,

<sup>5</sup>Department of Clinic and Medical Therapy, University of Rome "La

Sapienza", Italy, <sup>6</sup>Department of Internal Medicine, University of Rome Tor

Vergata, Rome, Italy, <sup>7</sup>Clinical Dietetics, Alma Mater Studiorum University

of Bologna, Italy, <sup>8</sup>Department of Endocrinology, University of Lund, Malmö, Sweden.

**Background and aims:** GWAS have shown new genetic variants to be associated with lipid traits. We evaluated these associations in the GENFIEV (GENetics, pathoPHYSiology and EVolution of type 2 diabetes) study, a multicenter nationwide Italian study designed to recruit individuals at risk of developing T2DM, whose clinical characteristics and lipid profile were measured.

**Materials and Methods:** In 864 subjects (56.6% women; age 49.5±11.2 yrs; BMI 29.1±5.3 Kg/m<sup>2</sup>) we performed an OGTT with measurement of C-peptide and fasting insulin. Insulin resistance was assessed by HOMA-IR, while beta-cell function was estimated by the Insulinogenic Index and minimal model analysis of plasma glucose and C-peptide. We measured lipid concentrations according to standard enzymatic methods. We genotyped 19 variants. Obesity (BMI≥30 kg/m<sup>2</sup>) was present in 40% and type 2 diabetes in 14.2%. Associations with lipid profile were investigated by linear regression while logistic regression was used to explore associations with MS and obesity. All analyses were adjusted for age, gender, BMI and type 2 diabetes, appropriately.

**Results:** As described in other populations, we found that in individuals at risk of diabetes rs1260326 (GCKR), rs780094 (GCKR) and rs17145738 (BCL7B,TBL2,MLXIPL) were significantly (p=0.05 or less) associated with increased triglycerides; rs12654264 (HMGCR) and rs780094 (GCKR) with high LDL-Cholesterol (C); rs4846914 (GALNT2) and rs1800775 (CETP) with low HDL-C; rs328 (LPL) with low triglycerides; rs1800588 (LIPC), rs328 (LPL) with high HDL-C. Rs1801282 (PPARG) was associated with high HOMA-IR; rs8050136 (FTO) with obesity; rs1260326 and rs780094 with MS. Moreover, new associations were found between rs1260326 (p=0.005) and high LDL-C; rs1260326 (p=0.0002), rs12654264 (p=0.01), rs17145738 (p=0.03), rs1800588 (p=0.01), rs3890183 (p=0.04) and rs780094 (p=0.0002) with increased Total-C and rs2156552 (p=0.03) with higher triglycerides.

**Conclusion:** While we confirm in our Italian cohort at risk for type 2 diabetes the association between lipid profile with some of the genetic variants previously identified by GWAS, new associations have been found as well. These observations need to be confirmed in other populations as well, and, even more importantly, it will be critical to assess whether causal alleles at each locus affect risk for cardiovascular disease.

**Genome wide expression profiling uncovers molecular mechanisms of diabetic cardiomyopathy**

J. Lasheras<sup>1</sup>, M. Pujals<sup>1</sup>, J.E. Feliu<sup>2</sup>, J.A. Villena<sup>1,3</sup>;

<sup>1</sup>Vall d'Hebron-Research Institute, <sup>2</sup>Universidad de Castilla-La Mancha,

<sup>3</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:** Cardiovascular disease is the major cause of mortality in diabetic patients. Risk factors such as hypertension and coronary artery disease contribute to the high prevalence of cardiovascular dysfunction in diabetic population. However, pathological and clinical studies have shown that diabetes is associated with impaired cardiac contractility independently of atherosclerosis or hypertension, a condition that is defined as diabetic cardiomyopathy. The disease is characterized by decreased diastolic function and reduced left ventricle ejection time. These functional alterations are accompanied by structural changes, including left ventricle hypertrophy and fibrosis in the advanced stages of the disease. At the cellular level, diabetic hearts present an abnormal oxidative metabolism characterized by the absolute reliance on

fatty acids as the main source for ATP production and a decrease in glucose utilization. Still, the underlying mechanisms of diabetic cardiomyopathy have not been unraveled. Here, we have undertaken a genome wide expression profiling study in hearts of diabetic mice to uncover the genetic pathways that lie beneath the development of diabetic cardiomyopathy.

**Materials and methods:** To study the mechanisms underlying the development of diabetic cardiomyopathy, we have performed a gene expression profile study in hearts of 12-week old diabetic db/db mice using DNA microarrays.

**Results:** At 12 weeks of age, db/db mice are severely diabetic, exhibiting fasting hyperglycemia and hyperinsulinemia. Associated to decreased cardiac contractility, hearts of diabetic mice exhibited a 15 % decreased in ventricular mass. Paradoxically, despite a decreased ventricular weight, hearts from diabetic mice showed cardiomyocyte hypertrophy. However, measurement of total genomic DNA content revealed a 20 % reduction in cell number in hearts of db/db mice. Such decrease in cellularity could be attributed to an increase in cell apoptosis, since diabetic hearts exhibited an increased number of caspase-3-positive cells. Genome wide expression profiling using DNA microarrays revealed that nearly 600 genes (P<0.01) were significantly altered in diabetic hearts. Gene enrichment analysis showed that most of down-regulated genes corresponded to genes associated with the immune function, although a decrease in genes involved in the regulation of apoptosis or glycolysis was also found. Among the up-regulated genes, a notable enrichment in genes related to fatty acid, ketone bodies and amino acid metabolism was found. Also, an increased expression of mitochondrial genes and genes involved in the contractile function of heart was observed. A screening for potential regulators of gene expression among the differentially expressed genes, found that members of the PPAR, PGC-1 and ERR families of transcriptional regulators were dysregulated in diabetic hearts.

**Conclusion:** Our results suggest that an alteration in the expression of transcriptional regulators of the PPAR, ERR and PGC-1 families could underlie the cellular and metabolic derangements observed in hearts of diabetic db/db mice.

## 1194

**Candidate genes for Alzheimer's disease in patients with type 2 diabetes mellitus**

M. Vankova, P. Lukasova, D. Vejrazkova, O. Bradnova, K. Dvorakova,

J. Vcelak, B. Bendlova;

Department of molecular endocrinology, Institute of Endocrinology, Prague, Czech Republic.

**Background and aims:** Many studies have revealed that type 2 diabetes mellitus (T2DM) is a risk factor for cognitive dysfunction or dementia, especially those related to Alzheimer's disease (AD). The aim of the presented study was to compare the frequencies of polymorphisms of candidate genes for AD in the sets of T2DM patients and non-diabetic subjects and to evaluate beta cell secretion, insulin sensitivity and lipid levels of the study subjects in relationship to the described polymorphisms.

**Materials and methods:** The study comprised of 1124 subjects. Detailed biochemical and anthropometric characteristics of 368 T2DM patients and 756 non-diabetic subjects were collected. Except of T2DM patients, oral glucose tolerance test with sampling for blood glucose, insulin and C-peptide was performed. Selected polymorphisms of candidate genes for Alzheimer's disease (APOE rs429358, rs7412, TOMM40 rs2075650, rs157580, rs8106922, PICALM rs3851179, GLP1R rs6923761, rs1042044) were determined by ABI TaqMan SNP Genotyping Assays. Statistics was done using NCSS 2004 (chi-square, Mann-Whitney, ANOVA).

**Results:** The genotypic distribution was significantly different between T2DM and non-diabetics only in PICALM gene (p<0.01). In non-diabetics, the homozygotes for minor allele in comparison to the homozygotes for common allele had higher insulin secretion (HOMA-F; p<0.05) and they had also lower insulin sensitivity (OGIS; p<0.05). There was no difference in lipid spectra between minor and common homozygotes in both sets.

**Conclusion:** Our study suggests that the AD risk allele of the polymorphism rs3851179 in the PICALM gene is more frequent in T2DM patients in comparison to non-diabetics. PICALM gene encoding phosphatidylinositol binding clathrin assembly protein, which is involved in AP2-dependent clathrin-mediated endocytosis at the neuromuscular junction, could be important also in the glucose metabolism.

## 1195

**Association between plasma lipids and mannose-binding lectin (MBL) genotype and circulating MBL levels in patients with type 1 diabetes**T.K. Hansen<sup>1,2</sup>, P. Høyem<sup>1,2</sup>, S. Thiel<sup>3</sup>, P. Rossing<sup>4,2</sup>, A. Flyvbjerg<sup>1,2</sup>, L. Tarnow<sup>4,2</sup><sup>1</sup>Department of Endocrinology and Internal Medicine, Aarhus University Hospital, <sup>2</sup>Department of Clinical Medicine, Aarhus University, <sup>3</sup>Department of Biomedicine, Aarhus University, <sup>4</sup>Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** Mannose-binding lectin (MBL) may activate the complement system upon binding to glycosylated proteins. MBL levels are elevated in patients with type 1 diabetes, and high MBL genotypes and serum concentrations are associated with susceptibility to micro- and macrovascular complications. Recent data suggest a role of MBL in lipid metabolism, and the aim of the present study was to investigate the association between MBL and circulating lipid levels in statin-naïve patients with type 1 diabetes.

**Materials and methods:** MBL genotypes and serum concentrations of MBL, total-, HDL-, LDL-cholesterol, and triglycerides were determined in an established cohort of 391 patients with type 1 diabetes (199 with diabetic nephropathy, 192 with persistent normoalbuminuria). None of the patients were taking lipid-lowering drugs at the time of sample collections.

**Results:** The mean age of the patients was 41.8±9.9 years, and the average duration of diabetes 27.2 ± 8.2 years. Polymorphisms in the MBL gene associated with low MBL levels were detected in 183 patients. There were no differences in triglycerides, total-, HDL- and LDL-levels between patients with high and low MBL genotypes. Among the 208 patients with high MBL genotypes, however, there was a strong positive correlation between MBL levels and total cholesterol ( $r=0.36$ ,  $P<0.0001$ ), LDL-cholesterol ( $r=0.41$ ,  $P<0.0001$ ) and triglycerides ( $r=0.28$ ,  $P<0.0001$ ) and a significant negative correlation to HDL-cholesterol levels ( $r=-0.20$ ,  $P=0.003$ ). When patients with high MBL genotypes were divided according to the median MBL level for the group, triglycerides, total- and LDL-cholesterol levels were significantly higher among patients with high MBL levels, while HDL-cholesterol levels were significantly lower as can be appreciated from the figure.

**Conclusion:** Plasma lipids are unaffected by MBL genotype, but there may be a common pathway leading to increased MBL levels and an unfavourable lipid profile in patients with type 1 diabetes.

## 1196

**The 9p21 myocardial infarction risk locus does not associate with peripheral artery disease in patients with type 2 diabetes mellitus**E. Russo<sup>1</sup>, D. Lucchesi<sup>1</sup>, L. Pucci<sup>2</sup>, S. De Cosmo<sup>3</sup>, M. Garofolo<sup>1</sup>, R. Miccoli<sup>1</sup>, V. Trischitta<sup>3</sup>, G. Penno<sup>1</sup>, S. Del Prato<sup>1</sup><sup>1</sup>Endocrinology and Metabolism, University of Pisa, <sup>2</sup>IBBA, CNR Pisa,<sup>3</sup>IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

**Background and aims:** The chromosome 9p21 (Chr9p21) locus can be considered today the most robust genetic markers for coronary artery disease (CHD). The association between this locus and CHD has been replicated several times. Subsequent work showed associations of Chr9p21 with a number of other cardiovascular disease traits, such as carotid artery plaque, stroke, aneurysms, heart failure and cardiovascular mortality, suggesting a more gen-

eral role in vascular biology. Importantly, Chr9p21 lacks associations with common cardiovascular risk factors, such as lipids and hypertension indicating that the locus exerts its effects through largely independent mechanisms. Recently, genome-wide association studies identified a significant association on Chr9p21 with ankle-brachial index (ABI), a noninvasive measure of peripheral arterial disease (PAD).

**Materials and methods:** It was the aim of our study to investigate whether the CAD locus on Chr9p21 (as represented by SNP rs2383206) is associated with continuous ABI and PAD (ABI<0.9) in 937 unrelated type 2 diabetic patients of European ancestry (550 males, 58.7%; 387 females, 41.3%). Typing was performed by means of TaqMan assay implemented on an HT7900 Applied Biosystems platform. Linear and logistic regression models were used to test the SNP for association with ABI and PAD.

**Results:** Patients were 59.2±7.5 years old with a diabetes duration (DD) of 10.4±9.0 years (BMI 29.4±5.4 kg/m<sup>2</sup>; sBP 142±19 mmHg, dBP 82±10 mmHg). HbA1c was 7.7±2.7% (median value 7.45%; first and third quartile thresholds 6.75 and 8.25%, respectively). Genotypes distribution was: AA (n. 146) 15.6%; GA (n. 452) 48.2%; GG (n. 339) 36.2%; 128 patients (13.7%) had PAD. The sample was in Hardy-Weinberg equilibrium as investigated by the chi-square test. Among genotypes have not been observed differences as far as age, DD, smoking, BMI, SBP, DBP, HbA1c, total-, LDL- and HDL-cholesterol, triglycerides, uric acid, fibrinogen, urinary A/C ratio and eGFR by MDRD. No association was found between the rs2383206 genotype and ABI considered as a continuous trait (AA: ; GA: ; GG: ; ANOVA oneway,  $p=$ ). Furthermore, no association was found between rs2383206 and PAD prevalence (AA 15.1%; GA 13.1%; GG 13.9%; chi-square 0.399,  $p=0.819$ ). No interaction was observed between rs2383206 and poor glycemic control defined as an HbA1c above the median or within the fourth quartile. No differences were observed between genders or in subjects with compared to those without family history of CHD. In a logistic stepwise regression PAD was associated with age, sBP, smoking ( $p<0.001$  for all), dBP, male gender ( $p=0.001$  for both) and A/C ratio ( $p=0.035$ ) (model 1) or CHD ( $p<0.001$ ) (model 2), but not to rs2383206 or HbA1c.

**Conclusion:** In our cohort of type 2 diabetes patients, the rs2383206 SNP, previously related to the CAD risk mainly in presence of poor glycemic control, does not associate with continuous ABI and PAD phenotypes.

### Predictors of ischaemic heart disease and cerebrovascular attack in late elderly diabetic individuals: the roles of HDL-cholesterol and the LDL-C/HDL-C ratio

T. Hayashi<sup>1</sup>, H. Itoh<sup>2</sup>, A. Araki<sup>2</sup>, H. Sone<sup>3</sup>, H. Watanabe<sup>4</sup>, T. Ohru<sup>5</sup>, K. Yokote<sup>6</sup>, M. Takemoto<sup>6</sup>, M. Noda<sup>7</sup>, K. Ina<sup>1</sup>, H. Nomura<sup>1</sup>, Japan CDM Investigators group;

<sup>1</sup>Department of Geriatrics, Nagoya University Graduate School of Medicine,

<sup>2</sup>Division of Diabetes, Metabolism and Endocrinology, Tokyo Metropolitan

Geriatric Hospital, <sup>3</sup>Department of Internal Medicine, Endocrinology

and Metabolism, Graduate School of Comprehensive Human Sciences,

University of Tsukuba, <sup>4</sup>Department of Clinical Pharmacology and

Therapeutics, Hamamatsu University School of Medicine, <sup>5</sup>Department of

Geriatrics, Tohoku University School of Medicine, Nagoya, <sup>6</sup>Division of

Diabetes, Metabolism and Endocrinology, Department of Internal Medicine,

Chiba University School of Medicine, Chiba, <sup>7</sup>Department of Diabetes

and Metabolic Medicine, National Center for Global Health and Medicine, Tokyo, Japan.

**Background and aims:** Dyslipidemia, especially LDL cholesterol (LDL-C), is a risk factor for ischemic heart disease (IHD) in middle-aged diabetic individuals. However, the factors predicting IHD and a cerebrovascular attack (CVA) in older patients are not well known.

**Materials and methods:** This study was designed as a prospective cohort study (Japan Cholesterol and Diabetes Mellitus Study) with 4,014 type 2 diabetic patients (1,936 women; mean age 67.4±9.5 years, median 70 years, n=126175 years; disease duration 9.6±8.0 years). The levels of lipids, glucose, and other factors such as blood pressure were investigated relative to IHD or a CVA using the multivariate Cox hazard model.

**Results:** One hundred fifty-three cases of IHD and 104 CVAs (7.8 and 5.7/1000 people per year, respectively) occurred over 5.5 years. A lower HDL cholesterol (HDL-C) level and the female gender were correlated with IHD in patients ≥75 years old (hazard ratio (HR): 0.629, P<0.01, 1.132, P<0.05), in contrast, a higher systolic blood pressure (SBP), hemoglobin A1C (HbA1C) and LDL-C were correlated with IHD in subjects <65 years old (P<0.05). In all subjects, a higher LDL-C/HDL-C ratio was correlated with IHD. HDL-C levels were also correlated with CVAs in patients ≥65 years old (OR: 0.536, P<0.01). Kaplan-Meier estimator curves showed that IHD occurred more frequently in patients <65 years old in the highest quartile for LDL-C/HDL-C ratio and in patients ≥75 years old in the lowest quartile for HDL-C. CVAs were also most frequent in patients ≥75 years old in the lowest quartile for HDL-C.

**Conclusion:** IHD and CVAs in late elderly diabetic patients were predicted by the HDL-C level. The LDL-C and HbA1C levels and SBP are risk factors for IHD in non-elderly individuals, and LDL-C/HDL-C may represent the effects of both the LDL-C and HDL-C levels. These age-dependent differences in risk are important for generating an individualized strategy to prevent atherosclerotic disease.

### Relationship between cardiovascular risk factors and adipokines in patients with diabetes and chronic hepatitis C

D. Ramona Maria<sup>1</sup>, R. Emilia<sup>1,2</sup>, P. Cristina<sup>1</sup>, N. Raluca<sup>1</sup>, E. Georgiana<sup>1</sup>, R. Florin<sup>3</sup>, R. Gabriela<sup>1,2</sup>;

<sup>1</sup>INDNBM N. Paulescu, <sup>2</sup>University of Medicine and Pharmacy Carol Davila,

<sup>3</sup>Emergency Military Hospital Carol Davila, Bucharest, Romania.

**Background and aims:** Of the study were to evaluate the associations between chronic hepatitis C (CHC), insulin resistance (IR), cytokines and cardiovascular risk, in patients with CHC and type 2 diabetes.

**Materials and methods:** Observational, multicenter study that included 113 patients with CHC and diabetes. There were followed anthropometric indicators (weight, height, waist circumference, BMI (body mass index)). Biochemical parameters followed were blood glucose, glycosylated hemoglobin, lipid profile (cholesterol, triglyceride, HDL-cholesterol), liver profile (ALT, AST,

GGT, bilirubin, albumin, total protein), blood count, cytokines (adiponectin, leptin, TNF-α, IL-6, resistin). IR was determined using Homeostasis model assessment (HOMA-IR). The liver fibrosis was non-invasively assessed using the Forns index; a value < 4.2 excludes liver fibrosis and a value > 6.9 is a predictor for significant fibrosis. The 10-year coronary heart disease (CHD) was calculated for each patient using the UKPDS risk engine.

**Results:** The average age of the evaluated patients was 53.3±7.8 years, 46% females (n=52), with type 2 diabetes for 2.3 years. Metabolic syndrome (MetS) was present in 88 patients (77.9%). Median serum concentrations of leptin, TNF-α, IL-6, resistin were higher in patients with UKPDS-CHD over 30 (all p<0.05). Using the UKPDS score, 8% (n=9) and 45% (n=51) of the patients presented an high and moderate risk for CVD. UKPDS-CHD score was strongly correlated with age (r=0.42, p=0.02), GGT (r=0.41, p=0.03), HOMA-IR (r=0.46, p=0.001), fasting insulinemia (r=0.215, p=0.022), systolic blood pressure (SBP) (r=0.32, p=0.03), TNF-α (r=0.38, p=0.02), IL-6 (r=0.28, p=0.034), cholesterol (r=0.29, p=0.045) and negatively correlated with adiponectin (r=-0.315, p=0.022) and HDL-C (r=-0.37, p=0.001). In this population multiple regression models controlling for BMI indicated that adiponectin (R(2) = 0.16, p=0.034), resistin (R(2) = 0.18, p=0.045), and IL-6 (R(2) = 0.112, p=0.048) were associated with SBP. Forns index >6.9 was associated with increased CHD risk (r=0.341, p=0.0001), HOMA-IR (r=0.47, p=0.001), leptin (r=0.317, p=0.001), TNF-α (r=0.467, p=0.001), IL-6 (r=0.404, p=0.001), resistin (r=0.361, p=0.001), adiponectin (r=-0.352, p=0.001).

**Conclusion:** Increased CHD risk and HOMA-IR are associated with high values of Forns index. Patients with hepatitis C and diabetes have a greater risk to develop cardiovascular diseases. The clinical impact of CHC on cardiovascular risk deserves particular attention because of the growing number of patients with CHC and diabetes. The primary importance of estimating CHD risk is for its use in treatment decision making and patient counseling.

1199

### Atherogenic dyslipidaemia and silent coronary artery disease in patients with type 2 diabetes

P. Valensi<sup>1</sup>, A. Avignon<sup>2</sup>, A. Sultan<sup>2</sup>, B. Chanu<sup>1</sup>, M. Nguyen<sup>1</sup>, E. Cosson<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Diabetology, Nutrition, Paris Nord

University, Bondy, <sup>2</sup>Department of Diabetology, Lapeyronie hospital, Montpellier, France.

**Objective:** To investigate whether elevated triglycerides and low high-density lipoprotein (HDL) cholesterol (atherogenic dyslipidemia) are predictive of risk for silent myocardial ischemia (SMI) or angiographic coronary artery disease (CAD) in asymptomatic patients with type 2 diabetes.

**Methods:** Cohort study in 1080 asymptomatic patients with type 2 diabetes, a normal 12-lead resting electrocardiogram (ECG), at least one additional cardiovascular risk factor and low density lipoprotein (LDL) cholesterol <3.4 mmol/L. Patients initially underwent screening for SMI by <sup>201</sup>thallium myocardial scintigraphy after an ECG stress test, a pharmacological stress test (dipyridamol injection), or both. Patients with SMI underwent coronary angiography.

**Results:** Overall, 60 (5.5%) patients had atherogenic dyslipidemia (triglycerides ≥2.26 mmol/L and HDL cholesterol ≤0.88 mmol/L). SMI was detected in 292 patients and CAD in 91 patients. CAD was associated with atherogenic dyslipidemia independently of LDL cholesterol levels (p=0.01). In multivariate analyses taking into account the parameters associated in univariate analyses with SMI and then CAD, SMI was associated with atherogenic dyslipidemia (odds ratio 1.8[1.0-3.3]), male gender (OR 2.1[1.5-2.9]), BMI (OR 0.97[0.94-1.00]), retinopathy (OR 1.4[1.1-1.9]), peripheral occlusive arterial disease (POAD: OR 2.5[1.6-3.8]) and mean blood pressure (OR 1.01[1.00-1.03]); CAD was associated with atherogenic dyslipidemia (OR 4.0[1.7-9.2]), male gender (OR 3.0[1.6-5.6]), BMI (OR 0.94[0.90-1.00]), retinopathy (OR 1.7[1.0-2.9]), POAD (OR 4.0[2.1-7.4]) and mean blood pressure (OR 1.03[1.01-1.05]). In the subgroup of 584 patients at LDL cholesterol <2.6 mmol/L, CAD was independently associated with atherogenic dyslipidemia (2.96 [0.97-9.03]; p=0.06).

**Conclusion:** In type 2 diabetic patients including those at LDL cholesterol goal, atherogenic dyslipidemia is associated with an increased risk of silent CAD. Management targeted to this dyslipidemic profile may help to reduce the high residual burden of cardiovascular disease.

## 1200

**Longitudinal changes in serum lipid profiles and their management in representative Australian patients with type 2 diabetes: The Fremantle diabetes study**T.M.E. Davis<sup>1</sup>, K.E. Peters<sup>1</sup>, B.A. Sillars<sup>1</sup>, S.A.P. Chubb<sup>2</sup>, D.G. Bruce<sup>1</sup>, W.A. Davis<sup>1</sup>;<sup>1</sup>School of Medicine and Pharmacology, University of Western Australia,<sup>2</sup>Biochemistry Department, Fremantle Hospital, Fremantle, Australia.

**Background and aims:** Clinical trial evidence of the cardiovascular benefits of statins in type 2 diabetes has changed management substantially, especially over the last 10 years. To examine the magnitude and effects of this change in a real-world setting, we analysed data collected over almost 20 years as part of the Fremantle Diabetes Study (FDS), an observational study of diabetes in an urban Australian community. Our aim was to compare serum lipid profiles and use of lipid-modifying therapies in the 1,296 type 2 participants recruited to Phase 1 (FDS1) between 1993 and 1996 with those of the 1,509 type 2 participants from the same postcode-defined area recruited to Phase 2 (FDS2) between 2008 and 2011.

**Materials and methods:** Comprehensive questionnaire, physical and biochemical data were collected at baseline in both phases. Patients attended after a >10-hour overnight fast with biochemical testing of fasting blood and urine samples performed in a nationally-accredited laboratory using methods that were the same for both Phases or recalibrated when assays changed.

**Results:** FDS2 patients were older than those in FDS1 (mean 65.4±11.7 vs 64.0±11.3 years,  $P=0.001$ ) but a similar proportion was male (51.8 vs 48.6%,  $P=0.10$ ). Statin use was substantially greater in FDS2 (65.9 vs 6.8%,  $P<0.001$ ) in association with a significantly lower serum LDL-cholesterol ( $2.3\pm 0.9$  vs  $3.3\pm 0.9$  mmol/L,  $P<0.001$ ). Serum LDL-cholesterol targets ( $<2.6$  mmol/L in primary prevention,  $<1.8$  mmol/L in secondary prevention) were met by 68.2% of statin-treated FDS2 patients. One third of FDS2 patients eligible for government-subsidised statin therapy (436 of 1,310) remained untreated. Use of fibrates remained low in FDS2 (2.2 vs 3.5%,  $P=0.05$ ).

**Conclusion:** There has been a substantial increase in statin use by Australians with type 2 diabetes over the last two decades. Most statin-treated patients achieve recommended LDL-cholesterol targets but many of those who are eligible for subsidised statin therapy are untreated. A low rate of fibrate use mirrors the comparatively weak evidence base for cardiovascular disease prevention in type 2 diabetes.

**Bone mineral density is reduced in half of Danish insulin dependent type 2 diabetes patients**

T.W. Boesgaard, on behalf of the CIMT Trial Group;

Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** Prevalence and incidence of low bone mass in patients with type 2 diabetes varies between anatomical region and population. The prevalence of osteoporosis in Denmark is estimated to 20% in women and 10% in men age 55–59 years, increasing to 30% and 15% in 60–64 years, respectively. Both diabetes and osteoporosis are related to bone fractures and vascular complications with increased mortality. Accumulating evidence indicates that the diseases have similar underlying patho-physiological mechanisms. The aim of the present study was to evaluate the prevalence and risk factors for osteopenia and osteoporosis in a Danish trial cohort of patients with type 2 diabetes.

**Materials and methods:** We investigated 429 patients with type 2 diabetes included in the Copenhagen Insulin Metformin Trial (CIMT), recruited from 8 diabetes outpatient clinics in the greater Copenhagen area. Inclusion criteria were age>30 years,  $HbA_{1c}>7.0\%$  and  $eGFR>60$  ml/min. Anthropometric measures, glycaemic status, plasma lipids and creatinine were determined at entry into the trial. Bone Mineral Density (BMD) was measured by Dual Energy X-ray Absorptiometry (DXA). Osteopenia was defined by any T score -1 to -2.5 and osteoporosis as any T score<-2.5. BMD measured in ( $g/cm^2$ ).

**Results:** A total of 429 patients (68% men), age  $61 \pm 9$  years [mean  $\pm$  SD], BMI  $32 \pm 4$  kg/m<sup>2</sup> [mean  $\pm$  SD],  $HbA_{1c}$   $8.5 \pm 1.0\%$  [mean  $\pm$  SD], duration of diabetes 13 years (range 1–40 years), serum creatinine 77 ml/min (range 38–193 ml/min). The prevalence of osteopenia was 43% (46% in men and 38% in women) whereas only 3% (2% of men and 4% of women) had osteoporosis. Patients with osteopenia and osteoporosis were older  $62 \pm 8$  vs  $60 \pm 10$  years,  $p=0.01$ , had lower BMI and lower  $eGFR$ ,  $p<0.03$  than patients with normal

BMD. Patients with elevated serum creatinine had lower femoral hip neck BMD,  $p=0.004$ . Glycaemic control did not differ between groups.

**Conclusion:** Almost half of patients with type 2 diabetes had reduced BMD which is more frequent than expected in age matched non diabetic controls in the Danish population. This was most pronounced in patients with impaired renal function. On the other hand fewer than expected suffered from osteoporosis.

**Socioeconomic status and ischaemic heart disease incidence in people with type 2 diabetes in Scotland**

S. Wild, N. Jones, D. McAllister, The Scottish Diabetes Research Network

Epidemiology Group;

University of Edinburgh, UK.

**Background and aims:** Type 2 diabetes mellitus (T2DM) is more prevalent in people with a lower socioeconomic status (SES) and risk of ischaemic heart disease (IHD) is higher both in people with T2DM and those of low SES. The aim of this study was to investigate whether T2DM and SES increase synergistically the incidence of non-fatal and fatal IHD.

**Materials and methods:** Data were extracted in 2008 from the Scottish Care Information - Diabetes Collaboration dataset and linked to national hospital admissions and mortality data. This analysis is based on the population of people with diagnosed diabetes in Scotland for the period 2005–2007. Data were aggregated by sex, age-group, presence of T2DM, and deprivation quintile (using the area-based Scottish Index of Multiple Deprivation). Poisson regression was used to estimate age and SES adjusted relative risk (RR) for T2DM for incident IHD by sex with comparison to the non-diabetic population and with further comparison to the most deprived quintile to test for interaction. Incident IHD was defined as either a hospital admission or death where I20–25 codes from the tenth revision of the International Classification of Diseases were recorded as primary cause of admission/death or where diabetes was recorded as the underlying cause and IHD listed as a contributing cause of death, when no record of heart disease in the previous ten years exists.

**Results:** Absolute risk of incident IHD was higher in men than women and in people with T2DM than people without diabetes and declined in all groups with decreasing deprivation (Figure). The age and SES-adjusted RR (95% confidence intervals) of IHD were 1.52 (1.47–1.56) for T2DM in men and 1.68 (1.63–1.74) for women. Compared to women who did not have T2DM and were in the most affluent quintile (Q5), relative risks (95% confidence intervals) of incident IHD were 1.31 (1.27–1.35) for women without T2DM in the most deprived quintile (Q1), 2.44 (2.22–2.68) for women with T2DM in Q5, and 3.14 (2.95–3.34) for women with T2DM in Q1 indicating a supra-additive interaction. Similar results were found in men, with RR of 1.33 (1.30–1.37) for men without T2DM in Q1, 2.08 (1.94–2.24) for men with T2DM in Q5 and 2.51 (2.37–2.65) for men with T2DM in Q1 compared to men without T2DM and in Q5.

**Conclusion:** These results indicate that the incidence of non-fatal or fatal IHD in Scotland is strongly related to T2DM status and SES, with evidence of synergy between T2DM and deprivation. These findings suggest that prevention of diabetes could contribute to reducing socio-economic inequalities in IHD incidence.

## 1203

### Temporal trend and geographical variation in hospitalisation for acute diabetic complications in Italy: a nationwide study, 2001–2009

F.L. Lombardo<sup>1</sup>, M. Maggini<sup>1</sup>, G. Bruno<sup>2</sup>;

<sup>1</sup>National Center of Epidemiology, ISS -National Institute of Health, Rome,

<sup>2</sup>Department of Internal Medicine, University of Turin, Italy.

**Background and aims:** Costs of hospitalization for diabetic people accounts for more than 50% of direct costs of the disease. Whereas hospitalizations due to chronic complications depends on long term quality of care, most hospital admissions for acute diabetic complications would have been avoidable with an appropriate outpatient care. In this nationwide study we investigated the temporal trends in hospitalization rates for preventable acute diabetic complications in period 2001–2009 and whereas regional variation within Italy influences this trend.

**Materials and methods:** National Health System data were used to identify 245,500 diabetes-related hospital admissions in Italian people from 2001 to 2009 for acute diabetic complications selecting all records with a primary or secondary discharge diagnosis including either hyperglycemic state: ketoacidosis (ICD-9-CM code: 250.1), hyperosmolar state (ICD-9-CM code: 250.2), other coma (ICD-9-CM code: 250.3), or hypoglycemic coma (ICD-9-CM code: 251.0). Hospitalization rate was calculated as the ratio of the number of hospital discharges and resident population per 100,000, and standardized by age and gender on 2001 Italian population.

**Results:** A mean annual number of 27,300 hospitalizations for acute diabetic complications were recorded in Italy in the period 2001–2009, representing 3.5% of all diabetes-related hospital discharges. Most of hospitalizations (94.4%) were due to hyperglycaemic complications (51.5% for ketoacidosis, 20.4% for hyperosmolarity and 22.5% for other coma) and 5.6% only for hypoglycemic coma. Over the study period, hospitalizations for acute complications decreased in Italy by 39%, from 56.3 per 100,000 in 2001 to 34.5 in 2009 ( $p$  for trend  $<0.001$ ); the decrease was similar for hyperglycaemic and hypoglycaemic complications. The reduction was higher in diabetic people aged 65 years and over, whereas rates were quite stable for those aged 0–39 years. No differences were observed between gender. Large geographical variation were found within Italy, with the lowest rate in the North (26.7 per 100,000 residents in 2009) compared to the Centre (34.1) and the South of Italy (45.4). In spite of similar decrease over time in hospitalization rates, variations across geographic areas remained stable over the study period, with a 3.6-fold difference between the lowest and the highest regional rates in 2009; in particular, an almost ten-fold regional difference in admission rates were found in people aged 0–19 years, which cannot be accounted for by differences in incidence rates of type 1 diabetes.

**Conclusion:** This is the one of the few available study examining hospital admissions for acute complications in diabetic people and the first nationwide study covering the population of Italy over a long time period. Despite hospitalizations for acute diabetic complications decreased by 40% over a nine years period, 22,052 hospital discharges were still registered in 2009. Large geographic variations are evident within Italy, and the amount of this excess cannot be attributed exclusively to regional variability in incidence and prevalence of the disease. The observed 3.6-fold difference is clinically important for a preventable complication with a significant potential for long-term morbidity and mortality. Prevention strategies are needed, particularly in areas identified with the highest rates.

## 1204

### Long-duration diabetes reduces physical function in Chinese adults: Da Qing IGT and diabetes study

Y. An<sup>1</sup>, E. Gregg<sup>2</sup>, P. Zhang<sup>3</sup>, J. Wang<sup>3</sup>, Q. Gong<sup>1</sup>, M. Engelgau<sup>2</sup>, G. Roglic<sup>4</sup>, P.H. Bennett<sup>5</sup>, G. Li<sup>6</sup>;

<sup>1</sup>Endocrine department, Fuwai Hospital, Beijing, China, <sup>2</sup>CDC, Atlanta, USA, <sup>3</sup>DaQing First Hospital, Daqing, China, <sup>4</sup>WHO, Geneva, Switzerland,

<sup>5</sup>NIDDK, Phoenix, USA, <sup>6</sup>China Japan Friendship Hospital, Beijing, China.

**Background and aims:** Diabetes has been shown to reduce physical function by self-report in Chinese adults, but no previous studies have documented such reduction using performance-based measures. This study evaluated physical functional levels measured by performance-based tests among the Chinese elderly with and without diabetes.

**Materials and methods:** In 1986, 630 persons aged 25–74 years with newly diagnosed type 2 diabetes (NDM) were identified by population-based diabetes screening and 519 with normal glucose tolerance (NGT) were selected for

comparison. In 2009, physical function was assessed in 237 (90% of the survivors) from the NDM cohort and 333 (85% of the survivors) from the NGT cohort of whom 230 had not developed diabetes by the time of the 23 year follow-up examination. Physical function was assessed using standardized protocols for grip strength (measured with a hand-dynamometer), balance (tandem stand), walking speed (meters per second), and chair stands (time to stand five times from an armless chair). Individuals were defined as having poor physical function if: 1) their grip strength was below 20th percentile of the population norm, 2) they were unable to balance for 10 secs or more, or 3) their walking speed was less than 0.7m/sec, or 3) they took more than 13.8 secs to complete the chair stands. We compared the physical performance between NDM and those never develop diabetes.

**Results:** Among the people with NDM, 56.1%, 41.9%, 38.4% and 51.9% had poor performance in grip strength, balance, walking speed, and chair stands respectively, compared to 44.0% ( $P<0.01$ ), 19.7% ( $p<0.001$ ), 22.2% ( $p<0.001$ ) and 42.1% ( $p<0.05$ ) of the participants in NGT group. After adjustment for age and sex, participants in the NDM cohort had significantly worse physical function than those in the NGT group (22.7kilogram (kg) force vs. 24.8 ( $p=0.0003$ ) in grip strength; 1.73 vs. 2.43 ( $p<0.001$ ) in balance score; 2.30 vs. 2.77 ( $p=0.0002$ ) in gait speed score. However, the difference in chair stands score between the two cohorts was modest (1.71 vs. 1.93 ( $p=0.05$ )). Participants who did not have diabetes at the end of the study had significantly better physical performance than those with diabetes in all four performance measures.

**Conclusion:** Diabetes significantly reduced many dimensions of objectively measured physical function among elderly Chinese with long duration diabetes.

## 1205

### What are the real risk factors for development of diabetes-related complications in patients with type 2 diabetes?

N. Müller, C. Kloos, G. Wolf, U.A. Müller;

Dept. Internal Medicine III, University Hospital Jena, Germany.

**Background and aims:** To prevent diabetes-related complications a good control of HbA<sub>1c</sub> and blood pressure is commonly accepted to be of major importance. In contrast to this, it is repeatedly reported, that some patients do not acquire complications in spite of off target HbA<sub>1c</sub> and blood pressure, whereas others with good metabolic control develop them. To shed some light on this question we studied the differences in HbA<sub>1c</sub> and blood pressure in patients with type 2 diabetes with and without diabetes-related complications and duration of diabetes of at least 20 years.

**Materials and methods:** We recruited all patients with diabetes mellitus type 2 and time since diagnosis of diabetes of at least 20 years from our electronic patient record EMIL<sup>®</sup>. Data from 296 patients (44 % female, mean age 72.2 years, time since diagnosis of diabetes 27.4 years, BMI 32.7 kg/m<sup>2</sup>, HbA<sub>1c</sub> 6.8 % (51mmol/mol), 91.6% were treated with insulin) were analysed. 9.5% (28) of the patients had no complications, 15.5% (43) had one mild; 9.5% (28) had one severe, 35.1% (104) had two and 31.4% (93) had three diabetes-related complications (retinopathy, nephropathy and neuropathy). We compared patients with no or one mild complication with patients with three complications. The mean follow up was 10.5y. HbA<sub>1c</sub> results were adjusted to the DCCT standard.

**Results:** Patients with no or one mild complication compared to patients with three complications have a lower mean (avg. of the follow up) HbA<sub>1c</sub> by 0.3% (7.4 vs. 7.7% (57 vs. 60.66 mmol/mol);  $p=0.042$ ), a significantly lower mean systolic blood pressure (144 vs. 148 mmHg;  $p=0.015$ ), but a higher diastolic blood pressure (82 vs. 78 mmHg;  $p=0.001$ ). We found no difference between patients with none or one mild complication and patients with three complications in respect of age (70.3 vs. 72.8y;  $p=0.062$ ), time since diagnosis of diabetes (27.3 vs. 28.4y;  $p=0.236$ ), mean BMI (31.5 vs. 32.7 kg/m<sup>2</sup>;  $p=0.236$ ), smoking status (current smokers 6.8 vs. 8.1%;  $p=0.368$ ) and social status (11.3 vs. 11.0;  $p=0.704$ ). In the regression analyses with age, blood pressure, BMI and HbA<sub>1c</sub> as co-variables, we found no significant association of age, BMI and HbA<sub>1c</sub> to the risk of diabetes-related complication. The association for blood pressure was also weak with an OR=1.007 ( $p=0.001$ ) for systolic blood pressure and an OR=0.893 ( $p=0.001$ ) for diastolic blood pressure.

**Conclusion:** In a group of patients with long term diabetes type 2 we found the risk for the development of diabetes-related complications only weakly associated to blood pressure and not associated to HbA<sub>1c</sub>. Those marginal differences to our understanding are unlikely to be the main and only cause for the different susceptibility of the patients in respect to diabetes related

complications. We assume different harmful and hereto unheeded co-factors are responsible for instance an autoimmune reaction or a genetic predisposition.

## 1206

### Does diabetic cardiomyopathy exist? Data from a series of 656 asymptomatic diabetic patients with known cardiac ischemic status

I. Pham<sup>1</sup>, M.-T. Nguyen<sup>2</sup>, I. Banu<sup>2</sup>, S. Chiheb<sup>2</sup>, C. Pillegand<sup>2</sup>, B. Chanu<sup>2</sup>, P. Valensi<sup>2</sup>, E. Cosson<sup>2</sup>;

<sup>1</sup>Explorations Fonctionnelles, <sup>2</sup>Service de diabétologie, AP-HP, HUPSS, Hôpital Jean Verdier, Bondy, France.

**Background and aims:** The aim of the study was to assess the prevalence of sub-clinical cardiomyopathy among patients with type 2 diabetes but without hypertension or coronary artery disease (CAD). Such cardiomyopathy would therefore be due only to diabetes or related metabolic disorders and could actually be named diabetic cardiomyopathy, in the absence of confounding factors.

**Materials and methods:** 656 patients with type 2 diabetes for 14±8 years (359 men, 59.7±8.7 years, HbA1c 8.7±2.1%) and at least one cardiovascular risk factor (hypertension 74%; dyslipidemia 70%; smoking habits 22%; peripheral occlusive arterial disease 10%, nephropathy 39%) but without cardiac symptom, had a cardiac echography at rest; underwent a stress cardiac scintigraphy to screen for silent myocardial ischemia (SMI), and in case of SMI, a coronary angiography to screen for silent CAD.

**Results:** SMI was diagnosed in 206 patients, and 71 of them had silent CAD. In the patients without hypertension or CAD (n=157), left ventricular hypertrophy (LVH: 24.1%) was the most frequent abnormality, followed by left ventricular dilation (8.6%), hypokinesia (5.3%), type 1 abnormal relaxation (4.8%) and systolic dysfunction (3.8%). Neither parameter was associated with LVH nor with left ventricular dilation nor with abnormal relaxation. In multivariate analysis, the parameters associated with hypokinesia were SMI (Odds ratio 14.7 [2.7–81.7], p<0.01) and peripheral occlusive arterial disease (OR 12.2 [1.4–103.1], p<0.05); those associated with systolic dysfunction were SMI (OR 114.6 [1.7–7907], p<0.01), HbA1c (OR 1.9 [1.1–3.2], p<0.05) and body mass index (OR 1.6 [1.1–2.4], p<0.05). LVH was more prevalent among hypertensive patients (hypertension without CAD 34.5%; with CAD 46.7%); and hypokinesia in the patients with CAD (CAD without hypertension 13.3%, with hypertension 13.7%).

**Conclusion:** In asymptomatic type 2 diabetic patients, diabetic cardiomyopathy is highly prevalent and is predominantly characterized by LVH. SMI, obesity and poor glycemic control contribute to systolic dysfunction and/or hypokinesia. Hypertension is associated with more LVH, and CAD with more hypokinesia.

	HTA- SC- n=157	HTA+ SC- n=411	HTA- SC+ n=15	HTA+ SC+ n=56
LVH, (%)	24,1	34,5	30,0	46,7

## PS 106 Microvascular complications in experimental studies

## 1207

### Diabetes-induced liver failure: effects of chronic 1,5-isoquinolinediol and nicotinamide treatment

M. Guzyk, T. Kuchmerovska;

Coenzymes, A.V. Palladin Institute of Biochemistry, Kiev, Ukraine.

**Background and aims:** The liver is known to be abnormally susceptible to oxidative damage from high ambient oxidant levels associated with diabetes. However, the exact mechanism by which oxidative stress could contribute to and accelerate the development of hepatic dysfunction in diabetic mellitus is only partly known and still need to be clarified. Moreover, hyperglycemia as was shown can be linked to cirrhosis and portal hypertension. The present study was designed to investigate the impact of experimental diabetes on the pathophysiological processes development in liver. We also tested whether 1,5-isoquinolinediol (ISO), a recent generation PARP inhibitors and nicotinamide (NAM), as drug with the wide range of metabolic effects can influence liver impairments associated with diabetes in therapeutic doses.

**Materials and methods:** All studies were carried out after 10 weeks of diabetes (streptozotocin, 55 mg/kg of body weight, i. p.) in male Wistar rats treated for 14 days with or without ISO (3 mg/kg, i. p.) and NAM (100 mg/kg, i. p.). The enzyme activities, protein, ascorbate, NAD<sup>+</sup> contents and endogenous antioxidant defence system states were assayed in liver. The activities of caspase 3 (Casp 3), cytochrome P 450 2E1 (CYP 2E1) and content of poly (ADP-ribose) polymerase 1 (PARP-1) were assessed by electrophoresis and immunoblotting.

**Results:** As evidence of oxidative stress and weakening of antioxidant defences in diabetic rats, we established reduction of the liver NAD<sup>+</sup>, substrate of poly ADP-ribosylation, and ascorbate levels by 35.3±4.1 % and 43.2±4.9 %, respectively, vs. control at p<0.05. Notably, that ISO supplementation to diabetic rats had no effect on blood glucose level while NAM caused a slight lowering effect. It was found more than 2.5 fold increases in mean CYP 2E1 expression in diabetic rats and groups treated with ISO as compared to controls. NAM administration was also accompanied with its ability to increase expression but to a less extent, p<0.05. It is not excluded, that exacerbation in mean CYP 2E1 expression in the livers of diabetic rats and animals treated with ISO and NAM may be associated directly or indirectly with elevated plasma ketone levels. We observed that caspase-3 was activated in the liver homogenates all groups animals as compared to control as result of PARP-1 cleavage. Administration of NAM partially inhibited Casp 3 activation. The SOD activity in diabetic rats was slightly increased as compared to control group (p<0.05). ISO and NAM exerted normalizing effects on this parameter.

**Conclusion:** Our findings indicate that PARP-1 inhibitors, such as ISO and NAM may be involved in improvements liver functions not only PARP-1 inhibition but also through multiple mechanisms including apoptosis. In conclusion, we suggest that these compounds might be useful agents for treating liver failures related to diabetes.

## 1208

### Metabolic deviations and liver injury in two diabetes mellitus models

J. Sokolovska<sup>1,2</sup>, S. Isajevs<sup>2</sup>, E. Rostoka<sup>2</sup>, L. Baumane<sup>1</sup>, J. Sharipova<sup>1</sup>,

O. Sugoka<sup>3</sup>, D. Isajeva<sup>2</sup>, I. Kalvinsh<sup>1</sup>, N. Sjakste<sup>1,2</sup>;

<sup>1</sup>Latvian Institute of Organic Synthesis, <sup>2</sup>Faculty of Medicine, University of Latvia, Riga, <sup>3</sup>Institute of Biology, University of Latvia, Salaspils, Latvia.

**Background and aims:** Fatty liver and non-alcoholic fatty liver disease (NAFLD) are implicated in pathogenesis of the insulin resistance and diabetes mellitus (DM). Glucotoxicity caused by chronic hyperglycaemia, as well as hyperlipidaemia have been shown to initiate accumulation of fat in the liver. Further, inflammation in the fatty liver might be mediated by increased iNOS expression followed by increased nitric oxide (NO) concentration. Changes in GLUT1 expression have been shown to be involved in development of some diabetic complications, however data about its role in NAFLD are scarce. In this work, we have studied changes in GLUT1, NO concentration and histological activity index (HAI) in two rat experimental models of DM: severely hyperglycaemic streptozotocin model (STZ model) and moderately hyperglycaemic hyperlipidaemic model, induced by high fat diet and low dose streptozotocin injections (HS model).

**Materials and methods:** Wistar rats aged 2 months were used. Rat STZ model was induced by single streptozotocin injection 50 mg/kg *i/v*. HS model was induced by feeding rats high fat diet for 2 weeks followed by 30 mg/kg *i/v* streptozotocin injection. 6 weeks after induction of both models of diabetes, GLUT1 mRNA and protein expression in liver were studied by means of real time RT-PCR and immunohistochemistry correspondingly. Production of NO was monitored by means of ESR spectroscopy of Fe-DETC-NO complex. Fibrotic, inflammatory and necrotic changes as well as fatty infiltration of the liver were expressed as HAI, as previously described.

**Results:** Mean non-fasting plasma glucose concentrations in the groups were: control  $5.48 \pm 0.45$  mmol/l, STZ  $58.11 \pm 5.53$  mmol/l, HS  $18.66 \pm 0.82$  mmol/l. In STZ group, plasma lipids were in similar concentrations as in control group, increased triglycerides and total cholesterol concentration were observed in the HS group (triglycerides: control  $1.46 \pm 0.09$  mmol/l, HS  $3.46 \pm 0.37$  mmol/l,  $p < 0.05$ ; total cholesterol: control  $1.60 \pm 0.04$  mmol/l, HS  $3.34 \pm 0.41$  mmol/l,  $p < 0.05$ ). Similarly, NO concentration was increased statistically significantly ( $p < 0.05$ ) in the liver of rats with severe hyperglycaemia (STZ group), but it did not change in HS rats (control  $36.8 \pm 10.3$  ng/g tissue versus STZ group  $142.1 \pm 31.1$  ng/g tissue,  $p < 0.05$ ; HS group  $35.4 \pm 9.8$  ng/g). Liver HAI was increased in STZ group,  $8.6 \pm 0.107$  versus control,  $2.60 \pm 0.74$ ,  $p = 0.008$ . In HS group, some insignificant increase in fatty degeneration was observed. GLUT1 protein expression was highly elevated in STZ group,  $16 \pm 3$  GLUT1 positive cells/mm<sup>2</sup> versus control,  $5 \pm 2$  GLUT1 positive cells/mm<sup>2</sup>,  $p = 0.007$ , but it did not change in HS group.

**Conclusion:** These results show that histologic changes similar to those observed in NAFLD in rat models of DM are caused by severe hyperglycaemia but not hyperlipidaemia, and are associated with increased NO production in the liver. Increased GLUT1 transporter expression might be involved in toxic effects of glucose in the liver.

## 1209

### Podocyte-specific angiotensin-1 overexpression ameliorates diabetes-induced albuminuria: implication of VEGF-A/VEGF receptor system

L. Gnudi<sup>1</sup>, D.A. Long<sup>2</sup>, K.E. White<sup>3</sup>, J. Pan<sup>1</sup>, M. Locatelli<sup>1</sup>, S.J. Smillie<sup>1</sup>, M. Kolatsi-Joannou<sup>2</sup>, A. Hayward<sup>1</sup>, A.S. Woolf<sup>4</sup>, C. Dessapt-Baradez<sup>1</sup>; <sup>1</sup>Cardiovascular Division, King's College London, <sup>2</sup>Nephro-Urology Unit, University College London, <sup>3</sup>Medical School, University of Newcastle, Newcastle upon Tyne, <sup>4</sup>Developmental and Regenerative Medicine Research Group, University of Manchester, London, UK.

**Background and aims:** Diabetic nephropathy (DN) is the leading cause of end-stage renal failure. Proteinuria is an early feature of DN and a strong predictor of disease progression, and activation of VEGF signalling pathway has been implicated in its pathogenesis. Diabetic glomerulopathy is characterised by increased angiotensin (Ang)-2 and reduced Ang-1 expression levels. Ang-1 activates Tie-2 receptor leading to endothelial cell survival and vessel integrity, while Ang-2 acts as an antagonist. Glomerular Ang-2 overexpression increases albuminuria in mice. We hypothesise that increased levels of Ang-2 in the diabetic glomeruli is an important player in the early stages of DN. Therefore by glomerular overexpression of Ang-1, and thus decreasing the Ang-2/Ang-1 ratio, we expect an amelioration of early diabetic glomerulopathy.

**Materials and methods:** We generated transgenic (TG) mice with podocyte-specific doxycycline (DOX)-inducible overexpression of Ang-1. Five weeks old male TG and non transgenic (nTG) mice were made diabetic with daily streptozotocin injections for 5 days. Non-diabetic (ND) and diabetic (D) mice were randomised to receive either DOX or vehicle (VEH: 5% sucrose) alone, in drinking water starting at 8 weeks of age for 10 weeks. Blood pressure and urinary albumin were measured at the end of the study, and tissues collected and processed for molecular determinations, and glomerular ultrastructural morphology analysis by electron microscopy.

**Results:** Diabetes was characterised by an increase in Ang-2/Ang-1 ratio and by an increase in albuminuria in D nTG VEH or DOX-treated mice (D-nTG vs ND-nTG,  $p < 0.05$ ). In D TG mice, the DOX-mediated increase in Ang-1 expression, resulted in decrease of the Ang-2/Ang-1 ratio and in a 40% reduction in albuminuria when compared to D nTG DOX-treated mice (D-TG-DOX vs D-nTG-DOX,  $p < 0.05$ ). Nephron expression levels were reduced in D animals ( $p < 0.05$ ), but no difference was observed between nTG and TG DOX-treated D mice. Podocyte-specific Ang-1 overexpression had no effect on albuminuria in ND mice. Diabetes was paralleled by kidney hypertrophy, mesangial expansion and thickening of the glomerular basement membrane

(D-nTG vs ND-nTG,  $p < 0.05$ ), but podocyte-specific Ang-1 overexpression did not ameliorate these parameters. Systolic blood pressure was raised in D mice but no difference was observed between TG and nTG DOX-treated D mice. Kidney cortex VEGF protein expression and VEGF receptor-2 phosphorylation were increased, while soluble VEGF receptor-1 (sFlt-1) was decreased in D versus ND mice (D-nTG vs ND-TG,  $p < 0.05$  for all). In D TG mice, overexpression of Ang-1 was paralleled by sFlt-1 upregulation and reduction in VEGF receptor-2 phosphorylation (D-TG DOX vs D-nTG DOX,  $p < 0.05$ ).

**Conclusion:** Podocyte-specific overexpression of Ang-1 reverse the diabetes-mediated decrease in Ang-1/Ang-2 ratio and ameliorates albuminuria accompanied by upregulation of sFlt-1 and inhibition of the VEGF-A/VEGF receptor signalling system. No effects of Ang-1 overexpression were observed in diabetes-mediated glomerular ultrastructural changes.

### Diabetes-induced changes in the extracellular matrix of the kidney and the effect of the Cu (II) chelator TETA

S. Brings<sup>1</sup>, S. Zhang<sup>1</sup>, B.Y. Chong<sup>1</sup>, D. Gong<sup>1</sup>, G.J.S. Cooper<sup>1,2</sup>; <sup>1</sup>School of Biological Sciences, University of Auckland, New Zealand, <sup>2</sup>Biomedical Research Centre, University of Manchester, UK.

**Background and aims:** Our group has shown that treatment with triethylenetetramine (TETA), a Cu (II) chelator, improves the function of the kidney and heart in diabetic humans and rats. One potential mechanism of action of TETA is the inhibition of oxidative stress in diabetes which can lead to non-enzymatic post-translational modifications (PTMs) of proteins. Extracellular matrix (ECM) proteins like collagen are particularly prone to the formation of PTMs due to the slow turnover rate. Thus structural and functional changes of the renal ECM in TETA- or placebo-treated diabetic and control animals were investigated, with a focus on PTMs of collagen.

**Materials and methods:** Male Wistar rats were injected with STZ (55 mg/kg, *i.v.*), to induce diabetes, or saline (for controls). TETA treatment (20 mg/day) was started 8 weeks after injection in half of the STZ- and saline-injected rats (4 groups,  $n = 12$  per group) and maintained for 8 weeks, after which the kidneys were collected. Kidney collagen was extracted and analysed for PTMs. Collagen content of renal cortex was determined by hydroxyproline measurement. Relative mRNA levels of collagen and related genes were measured via RT-qPCR. Relative protein levels were determined by western blotting. Statistical analysis was performed by two way ANOVA followed by Tukey-Kramer post-hoc test or Mann-Whitney U-test for non-parametric data.

**Results:** Messenger RNA levels for several isoforms of collagen were decreased in diabetes (Col1a2,  $p = 0.013$ ; Col4a4,  $p < 0.0001$ ; Col4a5,  $p = 0.004$ ; Col6a1,  $p = 0.014$ ; Col6a2,  $p = 0.008$ ; Col6a3,  $p = 0.035$ ) accompanied by a decrease in collagen protein levels ( $p = 0.003$ ). TETA treatment restored collagen protein levels to normal ( $p = 0.012$  STZ/placebo vs STZ/TETA) with no effect on mRNA levels. Protein levels of the collagen-degrading enzyme cathepsin L (CtsL) were increased in diabetes ( $p = 0.002$  and  $p = 0.0005$  for double chain and single chain respectively) along with mRNA levels ( $p = 0.013$ ). Pepsin digestibility of collagen extracts was decreased in diabetes ( $p = 0.045$ ). Collagen cross-linking enzyme lysyl oxidase (Lox) mRNA levels ( $p < 0.0001$ ) as well as protein levels ( $p = 0.017$ ) were increased. TETA had no effect on these parameters. The advanced glycation end-product (AGE) carboxymethyllysine (CML) was 4.2-fold more abundant in collagen extracts from diabetic kidneys ( $p = 0.014$ ) while the increase in extracts from TETA treated diabetic kidneys was only 2.0-fold (STZ/TETA group not significantly different from Sham/placebo).

**Conclusion:** Protein levels of collagen may be lower in diabetic kidneys due to the decreased mRNA synthesis. Increased CtsL mRNA and protein levels in diabetes can contribute further to the decreased collagen protein levels. Decreased pepsin digestibility of collagen in diabetes can be explained by increased Lox protein levels or enhanced AGE (CML) formation. Collagen protein levels were found to be lower in diabetes despite decreased pepsin digestibility of collagen, enhanced AGE formation and increased Lox protein level. Thus the correlation between AGE formation, *in vitro* pepsin digestibility and collagen accumulation in the diabetic kidney is not straightforward due to the effect of proteases like CtsL and transcriptional regulation. TETA treatment may normalise collagen levels in diabetic kidneys via inhibition of cathepsin L activity and/or the decrease of AGE-formation.

## 1211

### Exogenous and endogenous hydrogen sulfide protects endothelial cells from methylglyoxal-mediated damage

N.J. Murphy<sup>1</sup>, J.G. Mabley<sup>2</sup>;

<sup>1</sup>Brighton and Sussex Medical School, Hove, <sup>2</sup>School of Pharmacy & Biomolecular Sciences, University of Brighton, UK.

**Background and aims:** Methylglyoxal (MGO), a glycolysis derived reactive dicarbonyl compound has been implicated as a mediator of diabetic cardiovascular complications. MGO has been shown to cause endothelial cell dysfunction via increased oxidative stress. Hydrogen sulfide is an gaseous transmitter found in the vasculature and synthesized from the amino acid L-cysteine. Hydrogen sulfide has been demonstrated to have a protective role in the vasculature acting as a vasodilator and protecting the endothelium from oxidative stress. The aim of this study is to investigate whether hydrogen sulfide generated exogenously by a chemical donor or endogenously from L-cysteine is able to protect endothelial cell function from MGO-mediated dysfunction.

**Materials and methods:** The effects of MGO on acetylcholine-mediated NO dependent vasorelaxation were measured using ex vivo rat aortic rings exposed to 0.3 mM MGO for 2h, sodium hydrogen sulfide (0.3 and 0.5 mM) or L-cysteine (0.3 and 0.5 mM) was co-administered to investigate any protective effect. In vitro experiments using the EA.Hy926 human endothelial cell line were performed examining the effect of MGO±sodium hydrogen sulfide (0.3 and 0.5 mM) or L-cysteine (0.3 and 0.5 mM) on cell viability (MTT assay) and necrosis/apoptosis levels (propidium iodide/Hoechst staining followed by morphological analysis).

**Results:** MGO (0.3 mM) exposure increased the IC50 for acetylcholine-mediated relaxation from  $0.08 \pm 0.02 \mu\text{M}$  to  $0.42 \pm 0.1 \mu\text{M}$  ( $P < 0.05$ ), with protection being observed with both hydrogen sulfide ( $0.2 \pm 0.04 \mu\text{M}$  and  $0.12 \pm 0.02 \mu\text{M}$ ) and L-cysteine ( $0.13 \pm 0.02 \mu\text{M}$  and  $0.09 \pm 0.03 \mu\text{M}$ ) at 0.3 and 0.5 mM respectively ( $p < 0.05$  vs. MGO alone). Hydrogen sulfide and L-cysteine also protected the endothelial cell line from MGO-mediated loss of cell viability significantly increasing it from  $59 \pm 2\%$  with MGO 0.8 mM alone to  $75 \pm 2\%$  and  $84 \pm 1\%$  with 0.3 and 0.5 mM hydrogen sulfide and  $93 \pm 3\%$  and  $96 \pm 2\%$  with 0.3 and 0.5 mM L-cysteine respectively ( $p < 0.01$  vs. MGO alone). MGO 0.6 mM increased both necrosis (from  $4 \pm 1\%$  to  $20 \pm 5\%$  ( $p < 0.05$  vs. untreated cells)) and apoptosis (from  $1.2 \pm 0.6\%$  to  $7 \pm 2\%$  ( $p < 0.05$  vs. untreated cells)) levels in endothelial cells. Hydrogen sulfide 0.5 mM was again able to significantly protect against the MGO-mediated increase in cell death reducing necrosis to  $9 \pm 3\%$  and apoptosis to  $2 \pm 1\%$  ( $p < 0.05$  vs. MGO 0.6 mM alone). L-Cysteine also protected against MGO-mediated increase in necrosis and apoptosis reducing it to  $7 \pm 2\%$  and  $1.7 \pm 0.3\%$  respectively ( $p < 0.05$  vs. MGO 0.6 mM). Inhibition of the hydrogen sulfide synthesizing enzyme cystathionine- $\gamma$ -lyase with DL-propargylglycine increased the susceptibility of endothelial cells to MGO-mediated loss of cell viability while also partially blocking the protective effect of L-cysteine.

**Conclusion:** Hydrogen sulfide generated either directly from a chemical donor or indirectly from the endogenous substrate L-cysteine provided significant protection against MGO-mediated endothelial cell dysfunction. Hydrogen sulfide also protected the endothelial cell line from the MGO-mediated decrease in cell viability and increase in necrosis and apoptosis. These data suggest that hydrogen sulfide donors or therapies designed to increase endogenous production of hydrogen sulfide by the vasculature may be useful in reducing diabetic cardiovascular complications.

## 1212

### Semaphorin3g regulates endothelial cell fenestration and structure of foot processes

R. Ishibashi<sup>1</sup>, M. Takemoto<sup>2</sup>, Y. Akimoto<sup>2</sup>, S. Onishi<sup>1</sup>, T. Ishikawa<sup>1</sup>, E. Okabe<sup>1</sup>, P. He<sup>1</sup>, K. Kobayashi<sup>1</sup>, M. Fujimoto<sup>1</sup>, H. Kawamura<sup>1</sup>, G. Genov<sup>3</sup>, C. Betsholtz<sup>3</sup>, K. Tryggvason<sup>3</sup>, K. Yokote<sup>1</sup>;

<sup>1</sup>Department of Clinical Cell Biology and Medicine, Chiba University Graduate School of Medicine, Chiba, Japan, <sup>2</sup>Department of Anatomy, Kyorin University School of Medicine, Tokyo, Japan, <sup>3</sup>Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Switzerland.

**Background and aims:** Etiologies of diabetic nephropathy are largely unknown. Recent investigations have clarified the potential roles of glomerular podocytes in the development of diabetic nephropathy. The aim of this study is to analyze the functions of Semaphorin3g (Sema3g), which we have recently identified as a podocyte-expressed gene.

**Materials and methods:** Expression patterns of Sema3g mRNA were examined by Northern blot and in situ hybridization. Sema3g was expressed in Cos7 cells, and the proteins in the conditioned medium were analyzed by Western blotting. Sema3g knockout mice (Sema3g KO) were used to determine the function of Sema3g in vivo. Microarray analyses on Affymetrix GeneChip and reverse transcription-PCR (RT-PCR) were performed using isolated glomeruli.

**Results:** Sema3g mRNA was expressed in the kidney, heart, ovary, and at the highest level in the lung. In situ hybridization using embryonic day 18.5 kidneys revealed that Sema3g mRNA was expressed in podocytes at stages from the S-shaped body to mature glomeruli. Sema3g mRNA expression was also observed in arterial endothelial cells outside the glomeruli. The Sema3g gene encodes 782 amino acids consisting of a Sema domain and is classified as a secreted protein. We expressed Sema3g in Cos7 cells and detected approximately 100 kDa protein in the conditioned medium, confirming that Sema3g is a secreted protein. Since the functions of this protein in mammals are unknown, we generated Sema3g KO mice. These mice are viable and exhibit no overt phenotype. Light microscopy revealed that the Sema3g KO mice had no observable glomerular developmental defects. However, electron microscopy revealed thickening of the glomerular basement membrane and effacement of the podocyte foot processes, which mimicked diabetic glomerulosclerosis and the reduced number of endothelial fenestrations. Transcriptional analyses and RT-PCR reported a twofold increase in Sema3a mRNA expression in Sema3g KO mice compared with wild-type glomeruli. Sema3a is involved in glomerular endothelial and podocyte development, and therefore, there may be some compensation mechanisms by other semaphorins in the absence of Sema3g.

**Conclusion:** We identified Sema3g as a novel podocyte-expressed gene that may be involved in the regulation of glomerular endothelial fenestrations and the structure of podocyte foot processes, together with other semaphorins.

## 1213

### Wound healing rate is not impaired in mice with deficiency of liver-derived insulin-like growth factor-I (IGF-I)

I.R. Botusan<sup>1,2</sup>, V.G. Sunkari<sup>1</sup>, J. Grunler<sup>1</sup>, J. Svensson<sup>3</sup>, J.-O. Jansson<sup>4</sup>, C. Ohlsson<sup>3</sup>, K. Brismar<sup>1</sup>, S.B. Catrina<sup>1</sup>;

<sup>1</sup>Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden, <sup>2</sup>Endocrinology Dept, Carol Davila UMPH, Bucharest, Romania, <sup>3</sup>Institute of Internal Medicine, Sahlgrenska Academy, Sweden, <sup>4</sup>Institute of Neuroscience and Physiology, Sahlgrenska Academy, Göteborg, Sweden.

**Background and aims:** IGF-I has growth promoting effects and it is expressed in virtually all tissues. Liver-derived IGF-I constitutes the major part of circulating IGF-I. Mice with deficiency of liver-derived IGF-I (LI-IGF-I<sup>-/-</sup> mice) have 75% lower serum levels of IGF-I, but approximately unaffected postnatal body growth. However, liver-derived IGF-I exerts several important effects in adult life such as regulation of cortical bone mass. IGF-I has a positive effect on wound healing and is decreased in wounds with depressed regenerative potential as diabetic wounds. However, the importance of circulating IGF-I on wound healing is unknown. Here, we investigate the role of systemic IGF-I on the wound healing rate in LI-IGF-I<sup>-/-</sup> mice during normoglycemic and diabetic conditions.

**Materials and methods:** LI-IGF-I<sup>-/-</sup> mice with complete inactivation of the IGF-I gene in the hepatocytes were generated by using the Cre/loxP recombination system. Mice homozygous for LoxP but lacking Mx-Cre were used as controls. Inactivation of the IGF-I gene in hepatocytes was performed at 1 month of age. Diabetes was induced with streptozotocin (50 mg/kg, i.p. five consecutive days) in LI-IGF-I<sup>-/-</sup> mice and in the controls. Wounds were made on the dorsum of animals, and evaluated by photos taken every second day. At the end of the experiment, wound biopsies were taken for being analyzed regarding granulation, dermal regeneration (hematoxylin eosin), angiogenesis (isolectin staining), markers for inflammation (CD45) and recruitment of endothelial precursor cells (EPC) (qRT-PCR). The IGF system (GH, IGF-II, IGF-R and IGFBP3) is analyzed in the skin biopsies at the mRNA (qRT-PCR) and/or protein level (immunohistochemistry, western blot).

**Results:** The wound healing rate was similar in the LI-IGF-I<sup>-/-</sup> mice compared with the controls (50% wound closure at  $4 \pm 0.5$  days versus  $4 \pm 0.3$  days,  $p = \text{ns}$ ). Diabetes significantly delayed the wound healing rate both in the LI-IGF-I<sup>-/-</sup> and control mice ( $p < 0.05$ ). However, no significant difference was observed between diabetic animals, with normal or reduced hepatic IGF production (50% wound closure  $6 \pm 0.2$  days - diabetic controls versus  $6 \pm 0.1$  days diabetic LI-IGF-I<sup>-/-</sup> mice).

**Conclusion:** Liver-derived IGF-I does not affect wound healing in mice, neither in normoglycemic conditions nor in diabetes.

## 1214

### Notch signalling is activated in diabetes and contributes to defective wound healing

S.-B. Catrina<sup>1</sup>, V.G. Sunkari<sup>1</sup>, I.R. Botusan<sup>2</sup>, X. Zheng<sup>2</sup>, J. Grunler<sup>2</sup>, K. Brismar<sup>2</sup>;

<sup>1</sup>Department of Molecular Medicine and Surgery, <sup>2</sup>Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Diabetic wounds are characterized by impaired coordination of several mechanisms essential for healing as cell proliferation, cell differentiation and angiogenesis. Notch system together with hypoxia is a major player in cell differentiation and angiogenesis. It consists of several receptors (Notch 1-4) and ligands with a high specific cell-dependent effect. Binding of the ligands to the receptors is followed by proteolytic cleavage of the receptor by  $\gamma$ -secretase complex which results in the release of intracellular domain of the Notch receptor (NICD) that translocates in the nuclei and activates several genes. We have proposed to study the modulation of the Notch pathway in diabetes and its potential relevance in defective diabetic wound healing.

**Methods:** The modulation of Notch system by hyperglycemia was studied *in vitro* in human dermal fibroblasts (HDF) and *in vivo* in several animal models (db/db mice and Goto-Kakizaki (GK) rat) using the corresponding technique (western blot, transitory transfections with reporter gene assay or evaluation of target genes by quantitative RT-PCR). The functional consequence of the notch system modulation was studied *in vitro* by assessment of the migration of HDF and by angiogenesis assay (in human endothelial cells). Notch pathway inhibition was induced either nonspecific by  $\gamma$ -secretase inhibitors (DAPT, L-685,458) or by specific siRNA silencing of the Notch receptors (1-4). The effect of the notch inhibition on wound healing in diabetes was evaluated in db/db mice by local treatment with  $\gamma$ -secretase inhibitors.

**Results:** Hyperglycemia activates Notch pathway at multiple levels. The repressive effect of high glucose on migration (fibroblasts) and angiogenesis (endothelial cells) was cancelled by blocking the notch signaling. Specific modulation of Notch receptors (1-4) using siRNA pointed out on a central role of Notch1 in mediating the repressive effect of hyperglycemia. Moreover local treatment with gamma secretase inhibitors improved the wound healing in db/db mice (percentage of wound closure on day 12 was 60 +/- 2% (DAPT), 70 +/- 4% (L-685,458) and 43 +/- 5 % (Placebo) respectively ( $p < 0.01$ ). Blocking Notch signaling in diabetic wounds was followed by increase in granulation and epidermal formation, increase in blood vessel formation and increase in expression of SDF-1 alpha responsible for recruitment of EPCs.

**Conclusion:** Hyperglycemia activated Notch system and significantly impaired cell migration and angiogenesis. Blocking notch system improved cell migration, angiogenesis and in consequence wound healing rate in diabetic animals.

### Skeletal muscle perfusion and mitochondrial oxidative activity in type 2 diabetic patients according to microangiopathic complications

S. Chiheb<sup>1</sup>, S. Duteil<sup>2</sup>, E. Cosson<sup>1</sup>, C. Wary<sup>2</sup>, J. Paries<sup>1</sup>, A. Monnet<sup>2</sup>, B. Chanu<sup>1</sup>, D. Mesangeau<sup>2</sup>, P. Carlier<sup>2</sup>, P. Valensi<sup>1</sup>;

<sup>1</sup>Department of Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital AP-HP, CNRH-IdF, Paris-Nord University, Bondy, <sup>2</sup>Institut of Myology, NMR Laboratory, F-75651, CEA, I2BM, MIRCen, IdM NMR Laboratory, Paris, France.

**Background and aims:** We previously demonstrated that muscle perfusion and mitochondrial function were impaired in type 2 diabetic patients, especially in those with poor glycemic control and in those with multiple microangiopathic complications. The aim of this study was to assess the association of retinopathy, nephropathy and neuropathy with muscle perfusion and/or mitochondrial oxidative activity.

**Materials and methods:** We examined 96 type 2 diabetic patients, aged  $56.7 \pm 9.3$  years with body mass index  $27.5 \pm 4.1$  kg/m<sup>2</sup> and HbA1c  $7.6 \pm 1.8$  %, and without peripheral vascular disease. Multiparametric functional Nuclear

Magnetic Resonance (mpf-NMR) was performed to investigate muscle perfusion (Arterial Spin Labelled (ASL) NMR imaging (NMRI), oxygenation (dynamic proton NMR spectroscopy (<sup>1</sup>H-NMRS) of deoxymyoglobin (dMb) and mitochondrial function (spectroscopy <sup>31</sup>P) at rest, during and after an ischemic exercise of calf muscles. Symptoms and signs of peripheral neuropathy were graded using the Michigan Neuropathy Screening Instrument (MNSI). Vascular sympathetic activity was evaluated by the power of the low frequency spectrum of systolic blood pressure variations in the standing position (LF-SBP) using the Finapres<sup>®</sup> system.

**Results:** No relation was found between RMN parameters and retinopathy. Maximal muscle reperfusion after ischemic exercise correlated negatively with urinary albumin excretion rate ( $r = -0.328$ ,  $p = 0.002$ ) and was significantly lower in the patients with nephropathy ( $n = 24$ ) ( $p < 0.01$ ), even after adjustment on body mass index. Maximal muscle reperfusion was also lower in the patients with peripheral neuropathy (MNSI  $\geq 2.5/10$ ;  $n = 14$ ) ( $p = 0.057$ ). Re-oxygenation time of myoglobin correlated negatively with MNSI ( $r = -0.281$ ,  $p < 0.01$ ) and was longer (which means a defect of oxygenation) in the patients with peripheral neuropathy ( $p < 0.01$ ) than in those without. A defect of oxygenation was also associated with higher HbA1c levels ( $p < 0.01$ ) and lower vascular sympathetic activity ( $p = 0.01$ ), and remained associated with peripheral neuropathy after adjustment on age and HbA1c.

**Conclusion:** In type 2 diabetic patients the association between microalbuminuria and inadequate perfusion is consistent with the role of endothelial dysfunction in the impairment of muscle perfusion. The lower muscle oxygenation in the patients with peripheral neuropathy may result from a reduction in muscle sympathetic activity, possibly through a lower muscle perfusion.

## 1216

### Prevalence of liver histological abnormalities in type 1 diabetes and the long-term consequences

D.J. Harman<sup>1,2</sup>, R. Harris<sup>3</sup>, P. Kaye<sup>4</sup>, A. Gazis<sup>5</sup>, G.P. Aithal<sup>1,2</sup>;

<sup>1</sup>Hepatology, Nottingham University Hospitals NHS Trust, <sup>2</sup>NIHR NDDC Biomedical Research Unit, <sup>3</sup>General Medicine, Nottingham University Hospitals NHS Trust, <sup>4</sup>Histopathology, Nottingham University Hospitals NHS Trust, <sup>5</sup>Diabetes and Endocrinology, Nottingham University Hospitals NHS Trust, UK.

**Background and aims:** Patients with type 1 diabetes have a higher prevalence of raised liver enzymes than the general population. Ultrasound diagnosis of non-alcoholic fatty liver disease (NAFLD) has been reported to be common in type 1 diabetes despite associated insulin deficiency rather than insulin resistance. However, the histological spectrum of liver disease in type 1 diabetes and the natural history of chronic liver disease in this cohort is unknown. We describe the histological findings of patients with type 1 diabetes who had liver biopsy in a tertiary referral centre, and their long-term clinical outcome.

**Materials and methods:** The DIAMOND database, which contains longitudinal data for over 95% of patients with type 1 diabetes from an overall catchment population of 750,000 in Nottingham, England, was crossmatched with the clinical pathology database to identify those who had undergone liver biopsy. Case notes were reviewed to obtain follow up data, and identify liver and non-liver related outcomes.

**Results:** Out of 2,800 patients with type 1 diabetes, 57 patients underwent a total of 82 liver biopsies. Common indications for biopsy were abnormal liver enzymes (28 patients), malignancy (8), Hepatitis C staging (7) and clinical evidence of cirrhosis (3). On index biopsy, 86% had significant histological abnormalities (Figure 1) and 10 patients (17.5%) had cirrhosis. During a total follow up of 336.42 patient years (median 5.6 years), a further 4 patients developed cirrhosis, giving a cirrhosis prevalence of at least 500 per 100,000 population, compared with an estimated UK cirrhosis prevalence of 76.3 per 100,000 population. Portal hypertensive sequelae occurred in 11 patients (78.6%) with cirrhosis and hepatocellular carcinoma in 3 patients. Of those who had liver biopsy, 22 patients (38.6%) died during follow up. Non hepatic malignancy (9 patients), multiorgan failure (3) and liver failure (3) were the commonest mortality causes. Crude death rate was 6,539 per 100,000 person years, compared with national type 1 diabetes data of 1,878 per 100,000 person years. On age and sex adjusted multivariate analysis, diabetic nephropathy, raised GGT or prothrombin time, hypoalbuminaemia and non hepatic malignancy were associated with death.

**Conclusion:** Type 1 diabetes is associated with significant liver histology abnormalities and a higher than expected occurrence of cirrhosis, portal

hypertension and mortality. These findings have implications for long-term management of patients with type 1 diabetes.

Comparison of Framingham risk score, UKPDS risk engine, maximum-IMT, and LDL-C/HDL-C ratio for predicting coronary plaque in asymptomatic patients with type 2 diabetes

K. Fujihara<sup>1</sup>, H. Suzuki<sup>2</sup>, A. Sato<sup>3</sup>, S. Kodama<sup>1</sup>, Y. Heianza<sup>1</sup>, T. Ishizu<sup>3</sup>, K. Saito<sup>1</sup>, H. Iwasaki<sup>1</sup>, K. Kobayashi<sup>2</sup>, S. Yato<sup>2</sup>, A. Takahashi<sup>2</sup>, N. Yamada<sup>4</sup>, H. Sone<sup>1</sup>, H. Shimano<sup>2</sup>;

<sup>1</sup>Endocrinology and Metabolism, University of Tsukuba, Mito,

<sup>2</sup>Endocrinology and Metabolism, University of Tsukuba, <sup>3</sup>Cardiology,

University of Tsukuba, <sup>4</sup>Internal Medicine, University of Tsukuba, Japan.

**Background and aims:** Although risk scores can predict future cardiovascular events, they fall short in predicting near-future events. Recent studies showed that the combination of the Framingham Risk Score (FRS) and carotid intima-media thickness (IMT) improved the prediction of cardiovascular disease.

**Materials and methods:** This study aimed to compare the predictability of FRS, UKPDS Risk Engine (UKPDS), maximum-IMT (max-IMT), and LDL-C/HDL-C ratio (L/H) for coronary plaque by 64-slice coronary CT angiography (CCTA) in asymptomatic patients with type 2 diabetes (T2DM) patients. A total of 116 Japanese T2DM patients who had a max-IMT  $\geq 1.1$  mm, electrocardiogram (ECG) abnormality, or positive exercise ECG test results underwent CCTA. Definitions of coronary artery stenosis and vulnerable coronary plaque were luminal narrowing of  $\geq 50\%$  and any coronary plaque with positive vessel remodeling and low attenuation, respectively. The 10-year risk of coronary heart disease was calculated according to the FRS and UKPDS. These 2 risk scores or clinical variables individually, a combination of either risk score and max-IMT or L/H, and the combination of max-IMT and L/H were compared to areas under the curve (AUCs) in receiver operating characteristic curve analysis. Trends of proportion of coronary artery stenosis through tertile of max-IMT in each category of the 2 risk scores were analyzed with generalized liner model.

**Results:** Of the 116 patients, 68 had coronary artery stenosis and 31 had vulnerable coronary plaque. The AUCs of each variables are listed in table. Figure shows a modification in the prediction of coronary artery stenosis based on max-IMT.

**Conclusion:** The data suggest that the combination of risk score with max-IMT improves the prediction of coronary plaque in comparison with a risk score alone and the combination of max-IMT and L/H is superior to a risk score alone in its simplicity in prediction of vulnerable coronary plaque.

AUCs for coronary artery stenosis, and vulnerable coronary plaque. Data are AUC (95% CI).

	Coronary artery stenosis	Vulnerable coronary plaque
FRS	0.763 (0.674-0.853)	0.655 (0.544-0.766)
FRS and Max-IMT	0.788 (0.705-0.872)	0.711 (0.607-0.815)
FRS and LDL/HDL	0.766 (0.676-0.856)	0.658 (0.541-0.776)
UKPDS	0.785 (0.703-0.868)	0.686 (0.579-0.794)
UKPDS and Max-IMT	0.800 (0.720-0.879)	0.719 (0.614-0.824)
UKPDS and LDL/HDL	0.785 (0.702-0.868)	0.690 (0.581-0.799)
Max-IMT and LDL/HDL	0.736 (0.644-0.827)	0.712 (0.605-0.819)

1218

Silent myocardial ischaemia and diabetes: to screen or not to screen!

A. Avignon<sup>1</sup>, J. Daures<sup>2</sup>, A. Sultan<sup>1</sup>;

<sup>1</sup>Nutrition-Diabetology, CHU Lapeyronie, <sup>2</sup>Biostatistic, IURC, Montpellier, France.

**Background and aims:** Given the elevated risk of cardiovascular events and the higher prevalence of silent myocardial ischemia (SMI) in diabetic versus non-diabetic patients, screening asymptomatic diabetic patients for CAD is an appealing concept. Indeed, a common argument for identifying SMI in

asymptomatic patients in general is to intensify treatment of risk factors and to propose a coronarography for eventual revascularization. However, published data demonstrating that a prospectively applied screening program improves outcome in asymptomatic diabetic patient are still lacking. Our objective was to determine if patients with SMI+ and coronarography have a better survival than the patients with SMI who did not undergo coronarography. Survival was compared to the patients without SMI.

**Materials and methods:** In our department, we used to screen for silent myocardial ischemia in high risk diabetic patients, following the international recommendations. If SMI was diagnosed, a coronary angiography was indicated. All patients benefits of treatment of their risk factors following international guidelines.

**Results:** Since 2000, 913 high risk diabetic patients (706 type 2 diabetic patients and 207 type 1 diabetic patients) with normal baseline electrocardiography (ECG) were evaluated to identify patients with SMI, using myocardial perfusion imaging. 171 patients had SMI (SMI prevalence 18%). Coronarography was done in 94 patients SMI+. There was no difference regarding risk factors, nor diabetic complications nor treatment between the group who underwent coronarography and the one who did not. These patients were followed during a mean period of 6,5 years. Survival analysis was made for univariate analysis, using Kaplan Meyer methods. Covariables with  $p$ -value  $< 0.15$  at log-rank test were introduced in COX multivariate analysis. Significant variables were selected for final model selection through STEPWISE, BACKWARD, FORWARD methods. 79 patients died (8,6%), mainly from cardiovascular diseases (84%). In univariate analysis, presence of SMI was not associated with total mortality ( $p=0,2263$ ) nor cardiovascular mortality ( $p=0,57$ ). Furthermore, in the group of patients SMI+, coronarography was not associated with a better survival in multivariate analysis.

**Conclusion:** In conclusion, this observational study should argue for intensive cardiovascular risk factors treatment in diabetes in reducing cardiovascular mortality, with no argument for a benefit from SMI screening.

## 1219

### Activin A is derived from human epicardial adipose tissue and associates with decreased myocardial function and glucose metabolism in human diabetic cardiomyopathy

W.J.Y. Chen<sup>1</sup>, S. Greulich<sup>2</sup>, L.J. Rijzewijk<sup>1</sup>, R.W. van der Meer<sup>3</sup>, M. Bekaert<sup>4</sup>, H.J. Lamb<sup>3</sup>, A. de Roos<sup>3</sup>, J.A. Romijn<sup>5</sup>, J.W.A. Smit<sup>3</sup>, G. Vandenplas<sup>4</sup>, A.A. Lammertsma<sup>1</sup>, M. Lubberink<sup>1</sup>, J.B. Ruige<sup>4</sup>, M. Diamant<sup>1</sup>, D.M. Ouwens<sup>2</sup>; <sup>1</sup>VU University Medical Center, Amsterdam, Netherlands, <sup>2</sup>German Diabetes Center, Duesseldorf, Germany, <sup>3</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>4</sup>University Hospital Ghent, Belgium, <sup>5</sup>Academical Medical Center, Amsterdam, Netherlands.

**Background and aims:** Previously, we found that an enhanced release of activin A from epicardial adipose tissue in patients with type 2 diabetes (T2D) impairs cardiomyocyte function *in vitro*. The aims of the present study were to (1) determine activin A levels in intracoronary sinus and peripheral serum samples of both patients with and without T2D undergoing coronary artery bypass grafting (CABG), and (2) assess the association of systemic activin A levels with cardiovascular and metabolic parameters in both asymptomatic men with uncomplicated T2D and healthy controls.

**Materials and methods:** Serum activin A levels were determined in the two distinct cohorts by ELISA. Cohort 1 included 18 T2D patients and 9 age- and sex-matched non-T2D patients undergoing CABG. Cohort 2 involved 78 T2D men in whom inducible ischaemia had been excluded and 16 age-matched healthy men. Cardiac function was measured using magnetic resonance imaging, and myocardial glucose metabolism (MMRglu) was determined using <sup>18</sup>F-2-fluoro-2-deoxy-D-glucose positron emission tomography during a hyperinsulinaemic-euglycaemic clamp.

**Results:** In patients undergoing CABG, activin A levels were higher in the intracoronary sinus than in peripheral blood ( $1861 \pm 397$  vs  $270 \pm 84$  pg/mL,  $P < 0.001$ ). T2D patients had higher activin A levels in the intracoronary sinus than the non-T2D patients ( $1955 \pm 415$  vs  $1670 \pm 206$  pg/mL,  $P < 0.05$ ), whereas peripheral activin A levels were similar between both groups. In cohort 2, compared with controls, T2D patients had higher body mass index (BMI), systolic blood pressure (SBP), pulse wave velocity (PWV), left ventricular (LV) mass/volume ratio, and decreased LV diastolic function, clamp-derived insulin sensitivity and MMRglu (all  $P < 0.05$ ). Peripheral activin A levels were similar to cohort 1, and did not differ between T2D patients and controls. Yet, a significant negative association was found between activin A levels and MMRglu ( $r = -0.450$ ,  $P < 0.001$ ), but not whole-body insulin sensitivity in T2D patients. In a multivariate analysis, adjustment for age, BMI, insulin sensitiv-

ity, fasting glucose and insulin levels, did not affect this association. Furthermore, there was a positive association of activin A with LV mass/volume ratio and PWV. Whilst age and SBP were confounding factors for the relation with PWV ( $P = 0.13$ ), the association between activin A and LV mass/volume ratio remained significant after adjustment for age, SBP and BMI ( $P = 0.02$ ).

**Conclusion:** Intracoronary sinus, but not peripheral activin A levels are elevated in T2D patients vs non-T2D patients undergoing CABG. Yet, in T2D, peripheral activin A levels negatively associate with MMRglu and positively with LV mass/volume ratio. These data suggest that activin A may not only represent a useful biomarker, but may also be a causal factor in the development of diabetic cardiomyopathy.

### Adenosine triphosphate binding cassette transporter G1 expression in monocytes is associated with HDL-carboxymethyllysine in type 2 diabetes

K.C.B. Tan, J.G.S. Tsun, S.W.M. Shiu, Y. Wang, Y. Wong, S.S.Y. Yung, D.T.M. Chan;

Department of Medicine, The University of Hong Kong

**Background and aims:** Dyslipidemia in type 2 diabetes is characterized by hypertriglyceridemia and low HDL cholesterol level. In addition to quantitative changes in HDL, qualitative abnormalities in HDL particles have also been reported. Glycation of HDL is increased and may affect the anti-atherogenic property of HDL. For instance, advanced glycation of apo A1 impairs its ability to promote cholesterol efflux and to stabilize adenosine triphosphate binding cassette transporter A1 (ABCA1) *in vitro*. We aimed to evaluate the extent of advanced glycation in HDL by measuring N(epsilon)-(carboxymethyl)lysine (CML) in HDL and determine the impact on the anti-oxidative property of HDL and cholesterol transporters expression in monocytes.

**Materials and methods:** 30 type 2 diabetic patients and 30 matched controls were recruited. CML content in HDL was measured by sandwich ELISA. mRNA of cholesterol transporters ABCA1, ABCG1, and scavenger receptor class B type I (SR-BI) in peripheral monocytes was determined by real time quantitative PCR. The capacity of HDL to inhibit LDL oxidation *ex vivo* was determined by incubating HDL with a reference LDL in the presence of dichlorofluorescein which fluoresced upon interaction with lipid oxidation products.

**Results:** Diabetic patients had higher levels of HDL-CML than controls [ $5626$  ( $2493$ – $11826$ ) ng/mg vs  $4453$  ( $806$ – $7263$ ), median (interquartile range),  $p < 0.01$ ]. The ability of HDL from diabetic patients in protecting LDL against oxidation was impaired with more lipid peroxide formed during the incubation ( $3260 \pm 669$  fluorescence intensity vs  $2840 \pm 642$ ,  $p < 0.05$ ). The expression of ABCG1 in monocyte was decreased in diabetic patients ( $p < 0.05$ ), whereas the levels of ABCA1 and SR-BI were comparable between the two groups. There was an inverse correlation between serum levels of HDL-CML and monocyte ABCG1 expression ( $r = -0.32$ ,  $p = 0.01$ ) but no correlation was seen with ABCA1, SR-BI expression or with HDL anti-oxidative capacity.

**Conclusion:** Diabetic patients have increased amount of CML in HDL and the antioxidant property of HDL is impaired. There is an association between HDL-CML and the expression of ABCG1 in peripheral monocytes. Whether the expression of ABCG1 is directly influenced by HDL-CML warrants further investigation.

### Diabetics show better collaterals toward the culprit vessel at the time of their first acute coronary event

D. D'Amario, G. Zaccardi, G. Niccoli, S. Giubilato, A. Leo, N. Cosentino, D. Pitocco, G. Ghirlanda, F. Crea; Catholic University, Rome, Italy.

**Background and aims:** Diabetes is associated with a more extensive and severe coronary artery disease (CAD), however similar age of presentation of non diabetics has been described despite a more extensive CAD at the time of a first acute coronary syndrome (ACS), thus suggesting that protective mechanisms may act in diabetics.

**Materials and methods:** We evaluated angiographic CAD severity and quality of the collateral circulation toward the culprit vessel according to the

diabetic status in consecutive patients at their first ACS. One hundred and sixty-seven consecutive patients undergoing coronary angiography because of non-ST-elevation (NSTEMI)-ACS (53% unstable angina and 47% NSTEMI-myocardial infarction), as their first clinical manifestation of CAD, and showing obstructive atherosclerosis were prospectively included. CAD severity was graded according to Bogaty's stenosis score and extent index, while collateral filling was graded according to Rentrop classification toward culprit vessel showing a TIMI flow  $\leq 2$ .

**Results:** Forty-seven patients (28%) were diabetics. Diabetics and non diabetics were similar for age ( $69 \pm 12$  vs  $66 \pm 14$ ,  $p=0.11$ ). Multivessel disease rate was higher in diabetics as compared to non diabetics (68% vs 42%,  $p=0.003$ ). At multivariate analysis both stenosis score and extent index were predicted by diabetes ( $p=0.001$ ), stenosis score was predicted by male sex ( $p=0.03$ ) and extent index by lack of statins ( $p=0.05$ ). Good collaterals (Rentrop 2-3) were observed in 28 over 83 culprit vessel with a TIMI flow  $\leq 2$ . At multivariate analysis, good collaterals were predicted by diabetes (OR 2.33, 95% CI 1.45–6.54,  $p=0.002$ ) and inversely by extent index (OR 0.87, 95% CI 0.51–0.96,  $p=0.03$ ).

**Conclusion:** Diabetics show at their very first ACS a more extensive and severe coronary atherosclerosis as compared to non diabetics, despite a similar age of presentation. However, angiographically visible collaterals toward the culprit vessel are better developed in diabetics, suggesting that collaterals may delay onset of a first ACS acting as a protective mechanisms.

## 1222

### Hyperuricaemia as an independent predictor of vascular complications and mortality in diabetic patients: a meta-analysis

Y. Xu<sup>1</sup>, J. Bai<sup>2</sup>, Y. Liu<sup>3</sup>, X. Wu<sup>1</sup>, C. Shen<sup>2</sup>;

<sup>1</sup>Endocrinology, the First Affiliated Hospital with Nanjing Medical

University, <sup>2</sup>Epidemiology & Statistics, Nanjing Medical University,

<sup>3</sup>Geriatrics, the First Affiliated Hospital with Nanjing Medical University, China.

**Aims:** Diabetes Mellitus (DM) is undoubtedly one of the most challenging health problems in the 21st century and the number of diabetic patients diagnosed has reached 366 million in 2011. Complications due to diabetes are a major cause of disability, reduced quality of life and death. Much epidemiologic evidence was committed to risk factors related to development of DM and its complications. Elevated serum uric acid (SUA) or hyperuricemia (HUA), a member of metabolic syndrome, has been reported to be an independent risk factor for the development of DM. Recent series reports indicated different role of HUA in complications attributed to DM. Hence, a pooled analysis of those results of the relationship between elevated SUA and diabetic complications would be warranted. Our aim is to ascertain the role of elevated SUA in the development of complications in DM.

**Materials and methods:** A computerized literature search of Medline database, Embase database, and Pubmed database was conducted and the odds ratio (OR) and hazard ratio (HR) for per 1mg/dl increase in SUA in each study was calculated for some studies defined SUA as a categorical variable. Cochran's Q and  $I^2$  statistics were used to evaluate heterogeneity among studies and pooling odds ratio (OR) and hazard ratio (HR) with 95% confidence intervals (CIs) were calculated using random-effects models and fix-effects models. The pooled analysis was performed with STATA 10.0.

**Results:** In total, 11 articles (19 ORs and RRs) including 22,591 participants were included in the meta-analysis. In the forest plot, pooled estimates for the relationship suggested that each 1 mg/dl increase in SUA resulted in a 17.4% increase in the risk of diabetic vascular complications and a 10.8% increase in the risk of diabetic mortality. In the stratified-analysis, HUA was markedly associated with diabetic macro- and microvascular complications, the pooled ORs (95% CI) were 1.004 (1.001–1.008) and 1.684 (1.289–2.200), respectively. HUA was more common in patients with nephropathy, the risk of which would be double (2.019 [1.268–3.449]) with each 1 mg/dl increase in SUA. Moreover, the overall RR and HR were inconsistently significant across different populations and sample size. The positive correlation between HUA and vascular complications remained in Asian (1.333 [1.005–1.770]) and European population (1.765 [1.284–2.426]), whereas, not in Australian population (1.252 [0.820–1.911]). And this also happens in mortality attributed to HUA in European (HR [95% CI] equaled to 1.265 [1.105–1.448]) and Australian population (1.054 [0.969–1.146]). Studies with relative large sample size over 1000 presented a significant association between HUA and diabetic vascular complications and HR (95% CI) was 1.410 (1.074–1.852), while those with small sample size (< 1000) failed in positive association, HR (95% CI) was 1.410 (1.074–1.852).

**Conclusion:** Results of this meta-analysis supported that hyperuricemia was an independent predictor of vascular complications and mortality in diabetic patients, thus lowering SUA levels should be helpful for prevention and treatment of complications in DM.

### Reduction in stroke during intensified multifactorial treatment in microalbuminuric type 2 diabetic patients

J. Ølgaard<sup>1,2</sup>, F. Persson<sup>3</sup>, P. Rossing<sup>3</sup>, H.-H. Parving<sup>4,5</sup>, O. Pedersen<sup>6,7</sup>, P. Gæde<sup>2</sup>;

<sup>1</sup>Faculty of Health Science, University of Copenhagen, <sup>2</sup>Dept. of Internal

Medicine, Slagelse University Hospital, Slagelse, <sup>3</sup>Steno Diabetes Center,

Gentofte, <sup>4</sup>Dept. of Medical Endocrinology, Rigshospitalet, Copenhagen,

<sup>5</sup>Faculty of Health Science, Aarhus University, <sup>6</sup>Novo Nordisk Foundation

Center for Basic Metabolic Research, Faculty of Health Sciences,

Copenhagen, <sup>7</sup>Hagedorn Research Institute, Gentofte, Denmark.

**Background and aims:** Patients with type 2 diabetes have a high risk for stroke compared to non-diabetic patients and have a significantly poorer prognosis for long-term survival and disability leading to major personal and economic burden. Several risk factors have been identified, and in the Steno 2 study the intensive, multifactorial intervention approach has earlier been demonstrated to significantly lower the cardiovascular risk. This study aimed to compare the risk for stroke in the conventional and the intensively treated cohort in the Steno 2 Study.

**Materials and methods:** 160 type 2 diabetic patients with microalbuminuria (u-albumin 30–300mg/l) were randomized to conventional (n = 80) or multifactorial, intensified treatment. Patients in the conventional arm were followed according to national guidelines for treatment of diabetes. Patients in the intensive arm, treatment targeted several concomitant risk factors with both pharmacological and behavioral intervention and a special task group followed the patients at our center. Stroke was defined according to prespecified criteria and adjudicated by an independent committee whose members were unaware of the patients' treatment assignments.

**Results:** Mean follow up was 7.8 yrs. During follow up three patients in the intensive group experienced a total of three strokes (recurrence rate = 0%) and 11 patients in the conventional arm experienced 20 strokes (mean = 1.8, recurrence rate = 55%). Intensive intervention reduced the relative risk for stroke by 75% (unadjusted relative risk was 0.25 (0.07–0.89)) and absolute risk of stroke by 10%. Adjustment for risk factors did not alter this value significantly. Allocation to intensive treatment and baseline systolic blood pressure was identified as significant independent risk factors for stroke in a Cox regression analysis: HR 0.23 (0.07–0.84,  $p=0.026$ ) and HR 1.03 (1.01–1.06,  $p=0.009$ ), respectively. Baseline fasting HDL-cholesterol was of borderline significance (HR 0.10 (0.01–1.53,  $p=0.09$ ). There was no significant impact of baseline glycaemic control, UAER, eGFR, smoking, age and gender or diabetes duration.

**Conclusion:** Intensified multifactorial intervention is associated with significantly reduced risk for first and recurrent stroke in the Steno 2 cohort of microalbuminuric type 2 diabetic patients. This finding further emphasizes the importance of multifactorial intervention for significant and cost-effective cardiovascular protection.

## 1224

### Significant improvement of VO2 peak, after myocardial infarction, in type 2 diabetes when glycaemic level is well controlled during cardiac rehabilitation: the DARE Study

B. Vergès<sup>1</sup>, B. Patois-Vergès<sup>2</sup>, I. Robin<sup>1</sup>, J. Bertrand<sup>3</sup>, J. Feige<sup>3</sup>, M.-C. Iliou<sup>4</sup>, H. Douard<sup>5</sup>, B. Catargi<sup>5</sup>, M. Fishbach<sup>6</sup>, B. Delenne<sup>7</sup>, C. Cabanot-sarrau<sup>7</sup>, B. Pierre<sup>8</sup>;

<sup>1</sup>Hôpital du Bocage, Dijon, <sup>2</sup>Les Rosiers, Dijon, <sup>3</sup>Polyclinique Urban V,

Avignon, <sup>4</sup>Hôpital Broussais, Paris, <sup>5</sup>CHU Bordeaux, Bordeaux, France,

<sup>6</sup>Polyclinique Bordeaux Nord, Dijon, <sup>7</sup>CH Aix en Provence, <sup>8</sup>Centre Iris,

Marcy-l'Étoile, France.

**Background and aims:** It is well known that gain in VO2 peak, after cardiac rehabilitation (CR), is associated with reduced mortality and morbidity. Our group has previously shown that the VO2 peak improvement in CR, after an acute ischaemic heart event, is significantly lower in Type 2 diabetic patients and that response to CR seems to be impaired by poor glycaemic control.

**Materials and methods:** Thus, we set up a prospective multicenter study (DARE Study) in order to determine whether good glycemic control during CR may improve the gain in VO<sub>2</sub> peak. Fifty six patients with type 2 diabetes, HbA<sub>1c</sub>>7% and referred to CR after a myocardial infarction occurring during the previous month were randomized in an intensive treatment group with basal-bolus insulin therapy or in a control group in which the antidiabetic treatment at time of enrolment in the study was maintained. Final fructosamine, at the end of the CR program, was used to assess mean glycemic level during the 3–4 week CR period.

**Results:** For the whole diabetic population studied, the mean gain in VO<sub>2</sub> peak after CR was  $2.7 \pm 2.4$  ml/kg/min in absolute value and  $16 \pm 15$  % in relative value. Gain in VO<sub>2</sub> Peak after CR was negatively correlated with basal ( $r=-0.31$ ,  $p<0.05$ ) and final fructosamine ( $r=-0.36$ ,  $p=0.01$ ) and with basal ( $r=-0.35$ ,  $p<0.05$ ) and final HbA<sub>1c</sub> ( $r=-0.35$ ,  $p<0.05$ ). At the end of the CR program, the gain in VO<sub>2</sub> peak and the reduction in mean fructosamine level were not significantly different between the 2 treatment groups. But, patients who had final fructosamine level below the median value showed significantly higher gain in VO<sub>2</sub> peak in absolute value ( $3.5 \pm 2.5$  vs.  $1.7 \pm 2.4$  ml/kg/min,  $p=0.014$ ) and relative value ( $+20 \pm 13$  vs.  $11 \pm 14$  %,  $p=0.048$ ). In multivariate analysis gain in VO<sub>2</sub> peak was associated with final fructosamine level ( $p=0.028$ ) but not with age, gender, duration of diabetes, MI location, insulin treatment or basal fructosamine.

**Conclusion:** The DARE study shows that fructosamine level at the end of the CR-program is an important determinant of gain in VO<sub>2</sub> peak in patients with type 2 diabetes and that good glycemic control in CR is associated with significantly better gain in VO<sub>2</sub> peak, independent of the treatment used (insulin or not). These data indicate that good glycemic control of type 2 diabetes in CR, after myocardial infarction, is mandatory in order to get optimal gain in VO<sub>2</sub> peak.

### Glycosylated haemoglobin influences myocardial perfusion after pharmaco-invasive therapy

L.N. Matos, D. Rangel, F. Homem, J. Diniz, F. Perez, J.L. Herrmann, J.A. Marconi, I. Goncalves Jr, E. Stefanini, A.C. Carvalho;  
Cardiology Department, Federal University of Sao Paulo, Brazil.

**Background and aims:** Diabetes mellitus is a condition that is associated with coronary microvascular disease. The role of glycosylated hemoglobin (HbA<sub>1c</sub>) levels determined on admission of patients with acute ST elevation myocardial infarction (STEMI) remains unclear. We aimed to determine the metabolic variables, including serum levels of HbA<sub>1c</sub>, possibly correlated with coronary microvascular permeability observed after treatment with pharmaco-invasive (PI) strategy in patients who had STEMI.

**Materials and methods:** We evaluated consecutive patients with STEMI referred from low complexity health care units to tertiary care general hospital after thrombolysis with teneceplase (TNK) for performing coronary angiography within 6–24 hours (PI strategy). All subjects received TNK up to six hours after onset of STEMI symptoms. Were determined, after eight hours fasting, serum glucose, HbA<sub>1c</sub>, TSH, total cholesterol, HDL-cholesterol, and triglycerides, LDL-cholesterol was determined through Friedewald formula. The myocardial blush grade (MBG) was determined (Gibson technique) by a single operator, experienced, at the beginning of the coronary angiography, and after PI therapy. Myocardial perfusion was regarded as either present (MBG 2 or 3) or absent (MBG zero or 1). We selected individuals who had no myocardial perfusion at the beginning of the coronary angiography, which were divided into groups as follows: individuals who still had no myocardial perfusion (group 1) and individuals who had gained adequate myocardial perfusion (group 2) after cath.

**Results:** We evaluated 113 individuals, of whom 51 (45.1%) had no myocardial perfusion initially, with thirty in group 1 (24 men,  $58.6 \pm 11.2$  years), and 21 in group 2 (16 men,  $54.0 \pm 11.7$  years). Group 1 subjects, compared to group 2, had higher HbA<sub>1c</sub> levels ( $7.49 \pm 2.15$  vs.  $6.12 \pm 1.01$ ,  $p = 0.02$ ). There was no significant difference between the two groups for the other parameters analyzed.

**Conclusion:** We observed that individuals without myocardial perfusion after FI strategy showed higher HbA<sub>1c</sub> levels at admission. This parameter, known to be associated with coronary microvascular disease, may be related to the failure of the restoration of flow in the coronary microcirculation in the sample studied.

## 1226

### Cardiac response to 2 years of intensified structured multi-intervention vs standard care in type 2 diabetes: a randomised trial

A.P. Ofstad<sup>1</sup>, O.E. Johansen<sup>1</sup>, K.I. Birkeland<sup>2</sup>, L. Gullestad<sup>3</sup>, S. Urheim<sup>3</sup>, S. Aakhus<sup>3</sup>;

<sup>1</sup>Medical Research Department, Asker and Baerum Hospital, Vestre Viken Hospital Trust, Baerum, <sup>2</sup>Department of Endocrinology, Oslo University Hospital Aker, <sup>3</sup>Department of Cardiology, Oslo University Hospital Rikshospitalet, Norway.

**Background and aims:** Patients with type 2 diabetes (T2D) are at elevated risk for heart failure (HF) and premature cardiovascular (CV) mortality. However, despite a strong epidemiological link, there is data suggesting that intensive glucose lowering could in fact be associated with worsened HF and CV outcomes. Since this remains a controversial topic, we hypothesized that an intensified structured multiintervention program (STRUCT) aimed against multiple HF and CV risk factors (hyperglycaemia, dyslipidaemia and hypertension) would improve, or at least not be harmful to, myocardial function compared to conventional standard care (STAND).

**Materials and methods:** 100 patients with T2D and  $\geq 1$  CV risk factor (29% females, mean age (mean $\pm$ SD)  $58 \pm 10$ , diabetes duration  $6 \pm 6$  yrs, BMI  $30.1 \pm 5.5$  kg/m<sup>2</sup>, 12% coronary artery disease, 53% self-reported dyspnoea, HbA<sub>1c</sub>  $7.6 \pm 1.6$ %, LDL  $2.9 \pm 0.9$  mmol/L, blood pressure (BP)  $141 \pm 18/83 \pm 9$  mmHg, were randomized to STRUCT (n=50) or STAND (n=50) care for 2 years. The groups were well balanced at baseline (BL) in all measured variables except prevalence of microalbuminuria (STRUCT 62%/STAND 22%). STRUCT comprised lifestyle intervention and targeted pharmacological treatment to reach pre-specified targets (HbA<sub>1c</sub>  $\leq 6.5$ %, total/LDL cholesterol  $<5/3$  mmol/L, BP  $<130/80$  mmHg) whereas the STAND group remained under GP care following current guidelines. All underwent echocardiography (echo) including Tissue Doppler Imaging (TDI) at BL. 90 completed the study with repeated echo. Blood samples were drawn and cardiopulmonary exercise test (CPET) performed at BL and 2 years.

**Results:** The STRUCT group obtained a significant improvement in lipids and glycaemic control as compared to the STAND group (reductions at study end for HbA<sub>1c</sub>:  $-0.8 \pm 1.4/+0.2 \pm 1.4$  % [ $p=0.001$ ], LDL:  $-0.7 \pm 0.9/-0.4 \pm 0.7$  mmol/L [ $p=0.13$ ], triglycerides:  $-0.5 \pm 1.3/0.1 \pm 0.7$  mmol/L [ $p=0.012$ ], respectively), whereas reductions in BP were similar. At BL, E/e', a measure of left ventricular (LV) filling pressure, was elevated ( $13.3 \pm 4.7$ ; reference value:  $<8$ ). Parameters of systolic function was preserved over 2 years in both groups (Table). Whereas, E deceleration time increased in the STAND group, and E/A ratio increased in the STRUCT group, there were no significant differences in the overall group responses in diastolic function. Peak work capacity defined as max watt obtained on CPET, was improved in STRUCT group and decreased in STAND group (between-group  $\Delta$ :  $9.2 \pm 3.4$  W,  $p=0.007$ ).

**Conclusion:** Two years of intensified STRUCT intervention in patients with T2D improved HF risk factors and work capacity, and did not worsen systolic or diastolic LV function.

### Comparison of clinical and economic outcomes associated with DPP4i versus SU in combination with MET or PIO for the treatment of type 2 diabetes mellitus

K. Chen<sup>1</sup>, E. Wu<sup>1</sup>, D. Cheng<sup>1</sup>, A. Bensimon<sup>1</sup>, M. Bron<sup>2</sup>

<sup>1</sup>Analysis Group, Inc., Boston, <sup>2</sup>Global Health Economics and Outcomes Research, Takeda Pharmaceuticals International, Inc., Deerfield, USA.

**Background and aims:** To compare diabetes-related complications and healthcare utilizations and costs between diabetes patients treated with DPP4 inhibitors (DPP4i)-based combinations [DPP4i+metformin (MET) or DPP4i+pioglitazone (PIO)] vs. sulfonylurea (SU)-based combinations (SU+MET or SU+PIO).

**Materials and methods:** Data from MarketScan, a large U.S. commercial claims database, were analyzed to retrospectively compare outcomes between patients treated with DPP4i and SU combinations. The study sample consisted of patients with type 2 diabetes mellitus (T2DM) who were treated with DPP4i or SU combinations and had continuous eligibility from 6 months prior to the index date (date of combination therapy initiation) to 12 months following the index date. Rates of diabetic complications, healthcare utilization, and costs in the 12 month period following index date were compared between the treatment groups. Complications of interest included microvascular complications (e.g. diabetic retinopathy), macrovascular complications (e.g. atherosclerosis), and other diabetic complications. Cox proportional hazards models were used to compare the rates of complications and adjust for baseline characteristics. Generalized linear models or two-part models (in outcomes with excessive 0's) were similarly used for diabetes-related utilizations and costs.

**Results:** 56,741 patients were selected into the study sample (n=15,139 receiving DPP4i combinations; n=41,602 receiving SU combinations). At baseline, patients treated with DPP4i combinations exhibited higher rates of comorbidities. After adjustment for baseline characteristics including demographics, diabetes-related complications, comorbidities, utilization and costs, the hazard ratios of complications were significantly lower for patients treated with DPP4i combinations (microvascular complications: 0.872,  $P<0.0001$ ; macrovascular conditions: 0.933,  $P=0.0015$ ; other complications: 0.921,  $P<0.0001$ ). DPP4i patients also had lower adjusted diabetes-related utilization incidence rate ratios (hospitalization: 0.76; ER visits: 0.69; outpatient visits: 0.87; all  $P<0.0001$ ). DPP4i patients incurred higher mean diabetes-related prescription drug costs (\$1,629 vs. \$476,  $P<0.0001$ ) but lower all-cause medical services costs (\$6,731 vs. \$7,251,  $P<0.0001$ ).

**Conclusion:** While patients on DPP4i combinations incur higher diabetes-related drug costs, they were found to have lower all-cause medical services costs than patients treated with SU combinations. However, the cost-savings from medical services associated with DPP4i combination therapy were less than the incremental drug cost. Lastly, our study found that DPP4i-combination patients had lower rates of diabetes-related complications and healthcare utilization in the 12 month follow up period, compared to those treated with SU combinations.

### Pioglitazone and macrovascular outcomes during observational follow-up of PROactive: 6-year update

E. Erdmann<sup>1</sup>, E. Song<sup>2</sup>, R. Spanheimer<sup>3</sup>, A.-R. Van Troostenburg de Bruyn<sup>2</sup>, A. Perez<sup>2</sup>

<sup>1</sup>Medical Clinic III, University of Cologne, Germany, <sup>2</sup>Takeda Global Research & Development Center, <sup>3</sup>Takeda Pharmaceuticals North America, Deerfield, USA.

**Background and aims:** In PROactive, a double-blind, placebo-controlled outcomes study in type 2 diabetes mellitus (T2DM) patients with known macrovascular disease, pioglitazone provided a non-statistically significant 10% relative risk reduction for the primary composite endpoint (all-cause death, myocardial infarction [MI], acute coronary syndrome [ACS], cardiac intervention, stroke, major leg amputation, leg revascularization) and a statistically significant 16% reduction for the main secondary endpoint (death, MI, stroke) after a mean 34.5 mo. Of 5238 randomized patients, 3599 (74%)

subsequently entered a 10-yr non-interventional observational study with no exclusion criteria or allocation to study medication; patients are treated per standard medical practice.

**Materials and methods:** An interim 6-yr analysis used a Cox proportional hazard model to compare non-adjudicated macrovascular events (using the same endpoints excluding ACS) between pioglitazone and placebo based on patients' original randomization in PROactive.

**Results:** For the observational period alone (mean 5.8 yr, during which fewer than 15% of patients received pioglitazone at any time) or the combined PROactive double-blind and 6-yr observational period (up to 9.5 yr in total; mean 8.7 yr), there were no statistically significant differences in the primary or secondary endpoints for pioglitazone *versus* placebo (Table).

**Conclusion:** These results suggest that the improved cardiovascular outcome seen with pioglitazone during the double-blind period of PROactive did not persist during the observational period in the absence of continued pioglitazone treatment.

Treatment Period	Endpoint	Original treatment during double-blind period		Hazard ratio	95% CI	p-value
		Pioglitazone	Placebo			
Double-blind (PROactive, mean 34.5 mo)	Primary	(n=2605) 514 (19.7%)	(n=2633) 572 (21.7%)	0.90	[0.80, 1.02]	0.095
	Main secondary	301 (11.6%)	358 (13.6%)	0.84	[0.72, 0.98]	0.027
	All-cause death	177 (6.8%)	186 (7.1%)	0.96	[0.78, 1.18]	0.678
Observational only (mean 5.8 yr)	Primary	(n=1820) 767 (42.1%)	(n=1779) 766 (43.1%)	0.98	[0.89, 1.08]	0.687
	Main secondary	567 (31.2%)	553 (31.1%)	1.01	[0.90, 1.14]	0.869
	All-cause death	368 (20.2%)	363 (20.4%)	1.00	[0.86, 1.15]	0.976
Double-blind + observational (max 9.5 yr; mean 8.7 yr)	Primary	(n=2605) 1118 (42.9%)	(n=2633) 1147 (43.6%)	0.95	[0.87, 1.03]	0.216
	Main secondary	829 (31.8%)	855 (32.5%)	0.95	[0.86, 1.05]	0.293
	All-cause death	545 (20.9%)	549 (20.9%)	0.98	[0.87, 1.11]	0.797

Primary endpoint = composite of all-cause death, MI, cardiac intervention, stroke, major leg amputation, leg revascularization; in PROactive, also included acute coronary syndrome.  
Main secondary endpoint = composite of all-cause death, MI, stroke.

### Event rate assessment of myocardial infarction and stroke for pioglitazone relative to insulin in patients with type 2 diabetes mellitus

H. Liang<sup>1</sup>, A. Perez<sup>1</sup>, J. Yang<sup>2</sup>, C. Vallarino<sup>1</sup>, G. Fusco<sup>1</sup>, M. Bron<sup>2</sup>, V. Harikrishnan<sup>2</sup>, G. Joseph<sup>1</sup>, S. Yu<sup>2</sup>

<sup>1</sup>Takeda Global Research & Development Center, Inc., <sup>2</sup>Takeda Pharmaceuticals International, Inc., Deerfield, USA.

**Background and aims:** There is a paucity of data on the risk of cardiovascular (CV) events in patients with type 2 diabetes mellitus (T2DM) receiving pioglitazone (PIO) compared with insulin (INS). In this retrospective cohort study, the event rates of myocardial infarction (MI) and stroke in new users of PIO and INS were assessed.

**Materials and methods:** Data were extracted from May 1, 2000 to June 30, 2010 from the i3 InVision Data Mart, a US medical and prescription records database representing approximately 47 million covered lives during the period of analysis. Key outcomes were incident cases of a composite of MI and stroke requiring hospitalisation. A composite endpoint of all-cause mortality, MI and stroke was also created for a pre-planned additional analysis using death records obtained from the US Social Security Administration in March 2012. Kaplan-Meier curves were generated for these outcomes with adjustment of inverse probability weights derived from propensity scores. Hazard ratios (HR) for PIO versus INS and 95% confidence intervals (CIs) were estimated using Cox proportional hazards models including all patients, with inverse probability weights derived from propensity scores.

**Results:** A total of 56,536 type 2 diabetes patients (PIO: 38,588; INS: 17,948) aged  $\geq 45$  years were selected (mean age: 58.1 and 59.7 years, male gender: 59.6% and 53.0%, mean follow-up: 2.2 and 1.9 years, for PIO and INS, respectively). For the composite of MI and stroke, the incidence rate was lower for PIO (717 vs 2067 per 100,000 patient-years); the HR for PIO vs INS was 0.44 (95% CI [0.39, 0.50],  $p<0.0001$ ) (Table). Over the first 6 years, incidence rates of the composite of MI and stroke were higher in the INS group than in the PIO group. When compared individually, the risks of MI and stroke were both significantly lower in the PIO group: the HR for PIO versus INS for MI was 0.49 (95% CI [0.41, 0.57],  $p<0.0001$ ), and for stroke was 0.37 (95% CI [0.31, 0.45],  $p<0.0001$ ). In the analyses by gender, age, congestive heart failure, pre-index antidiabetic and lipid-altering medication use, PIO lowered the risk of the composite of MI and stroke in every subgroup compared with INS. Based on the additional analysis, the risk of all-cause mortality plus MI

or stroke was lower in the PIO group than in the INS group; HR for PIO versus INS was 0.37 (95% CI [0.35, 0.40],  $p < 0.0001$ ).

**Conclusion:** The results indicate that PIO was associated with significantly lower risk of MI and stroke requiring hospitalisation compared with INS. The results were similar when all-cause mortality was added as a component of the composite endpoint in the analysis.

Comparison of Composite Endpoints between PIO and INS			
Endpoint	HR (PIO vs INS)	95% CI	P Value
MI/Stroke	0.44	[0.39, 0.50]	<0.0001
All-cause mortality/MI/Stroke	0.37	[0.35, 0.40]	<0.0001

### MACE associated with pioglitazone: a meta-analysis of randomised, controlled trials

A. Perez, E. Song, A. Edmonds;

Takeda Global Research & Development - US, Deerfield, USA.

**Background and aims:** The benefit of pioglitazone (PIO) with respect to major adverse cardiovascular (CV) events (MACE) has been shown in previous studies.

**Materials and methods:** This analysis evaluated risk of MACE (primary; composite of CV death and nonfatal myocardial infarction or stroke) and serious CHF (secondary) in patients with type 2 diabetes mellitus (T2DM) receiving PIO ( $n=12,506$ ) vs placebo or active control ( $n=10,212$ ) in all 36 randomized controlled trials in the PIO clinical database. Treatment durations were 4 months to 4 years. Events were identified by searching preferred terms of adverse events identified through standard safety monitoring; in 3 studies, pre-specified central adjudication was performed. The primary endpoint was time from first dose to first event; hazard ratios (HRs) and 95% CIs for events on PIO vs comparator (COMP) were calculated using a Cox proportional-hazards model stratified by study with treatment as the independent variable. Kaplan-Meier estimates were also produced.

**Results:** The primary analysis showed a statistically significant reduction in risk of MACE with PIO vs COMP (HR, 0.82; Table), and Kaplan-Meier plots showed shorter time to first event with COMP. Secondary analyses as well as sensitivity analyses (also in the Table) showed similar results. The analysis also confirmed the known CHF risk of pioglitazone (HR for CHF causing hospitalization, 1.41; 95% CI, 1.15–1.74), with no corresponding increase in mortality.

**Conclusion:** This analysis supports the CV safety of PIO with respect to standard MACE endpoints; PIO consistently showed favorable CV outcomes compared with placebo and active control in T2DM, independent of background CV risk.

Analysis	Study Set	N	HR (95% CI) for MACE (PIO vs COMP)
Primary analysis	All controlled studies	22718	0.82 (0.71, 0.95)
	Double-blind controlled studies	22131	0.82 (0.71, 0.95)
Secondary analyses	Controlled studies excluding PROactive	17480	0.82 (0.62, 1.09)
	PROactive study	5238	0.82 (0.70, 0.97)
Sensitivity analyses (all controlled studies)	Excluding events >30 days after last dose	22718	0.83 (0.72, 0.97)
	Excluding studies with no MACE	20569	0.82 (0.71, 0.95)

### An assessment of all-cause mortality for pioglitazone compared with insulin in patients with type 2 diabetes mellitus

S. Yu<sup>1</sup>, J. Yang<sup>1</sup>, M. Bron<sup>1</sup>, A. Perez<sup>2</sup>, C. Vallarino<sup>2</sup>, G. Fusco<sup>2</sup>, H. Liang<sup>2</sup>, V. Harikrishnan<sup>1</sup>, G. Joseph<sup>2</sup>;

<sup>1</sup>Takeda Pharmaceuticals International, Inc., <sup>2</sup>Takeda Global Research & Development Center, Inc., Deerfield, USA.

**Background and aims:** Recent studies have examined the effects of antidiabetic agents on all-cause mortality in patients with type 2 diabetes mellitus (T2DM), with the data showing mixed results. This assessment explored all-cause mortality in new users of pioglitazone (PIO) or insulin (INS) for treatment of T2DM.

**Materials and methods:** We conducted a retrospective study of patients initiating PIO or INS treatment which extracted data from May 1, 2000 to June 30, 2010 from the i3 InVision Data Mart, a US claims database representing approximately 47 million covered lives during the period of analysis. The study's first analysis focused on cardiovascular, cancer, and bone endpoints. As a preplanned Stage II assessment, the mortality of the studied patient cohort was analysed with the patient data linked to death records obtained from the US Social Security Administration (SSA) in March 2012. A death record was considered a valid and non-censored event in the analyses if it occurred between the date of last medication/treatment/diagnosis observed in the i3 InVision Data Mart minus 30 days, and the date of the last day of insurance eligibility plus 60 days or June 30, 2010 (the study end date), whichever was first. Incident cases of death were confirmed by the SSA by matching a number of patient parameters: social security number, date of birth, last name, first name, and middle initial. Kaplan-Meier curves were generated for the occurrence of deaths in the PIO and INS groups with adjustment of inverse probability weights derived from propensity scores. Hazard ratios (HR) for PIO vs. INS and 95% confidence intervals (CIs) were estimated from Cox proportional hazards models including all available patients, with inverse probability weights derived from propensity scores.

**Results:** A total of 56,536 T2DM patients (PIO: 38,588; INS: 17,948) aged  $\geq 45$  years were selected from the i3 InVision Data Mart (mean age: 58.1 and 59.7 years, male gender: 59.6% and 53.0%, mean follow-up: 2.2 and 1.9 years, for PIO and INS; respectively). The total number of deaths identified was 2268 (PIO: 670; INS: 1598). The Kaplan-Meier curves for PIO and INS are shown in the attached figure. The risk of all-cause mortality was significantly lower in the PIO group compared with the INS group; HR for PIO vs INS was 0.334 (95% CI [0.306, 0.364],  $p < 0.0001$ ). In a subgroup analysis by gender, age, congestive heart failure, pre-index antidiabetic and lipid-altering medication use, all-cause mortality was significantly lower in the PIO group compared with the INS group in every subgroup analysed.

**Conclusion:** In this analysis, the PIO-initiating group had significantly lower risk of all-cause mortality compared with the INS-initiating group.

## 1232

### A comparative study with metformin and pioglitazone versus metformin alone in nonalcoholic fatty liver disease in newly detected glucose intolerant patients

S.S. Sultana, F. Amin, A. Rahman, F. Afsana;  
BIRDEM, Dhaka, Bangladesh.

**Background and aims:** Non Alcoholic Fatty liver disease (NAFLD) is a hepatic manifestation of metabolic syndrome. The pathogenesis of steatosis and cellular injury is thought to be related mostly to insulin resistance. Insulin sensitizing drugs showed promising results in number of trials.

**Material and methods:** This is an open label clinical trial in newly detected Diabetes Mellitus (DM) and Impaired Glucose Intolerance (IGT) patients with raised ALT and NAFLD, to evaluate the effectiveness and superiority of pioglitazone and metformin combination to metformin alone. Forty nine patients with newly detected abnormal glucose tolerance, naïve to any anti-diabetic drug, were randomly selected, from the gastroenterology out-patient department BIRDEM, with the findings of ultasonogram changes of fatty liver and raised ALT and assigned to 6 months treatment with pioglitazone 30 mg plus metformin 1700 mg daily (Group 1, n=27) or only metformin 1700 mg alone (Group 2, n=22).

**Results:** Mean ( $\pm$ SD) age (yrs) of the study population was 45.80 $\pm$ 8.54, male female distribution of the study subjects were 65.3% and 34.7% respectively. Significant reduction of ALT, F, ABF, HbA1c, cholesterol, triglycerides of the study population were achieved either by metformin alone or with combination after six months [ (visit 1 vs visit 3, Mean $\pm$ SD) ALT: 97.99 $\pm$ 22. vs 55 $\pm$ 17.49 u/L, (p= 0.000); F : 9.1 $\pm$  1.9 vs 6.64 $\pm$ 0.94, mmol/L, (p=0.000); ABF: 13.3 $\pm$ 2.5 vs 8.69 $\pm$ 1.21 mmol/L, (p=0.000); HbA1c: 8.1 $\pm$ 0.9 vs 6.87 $\pm$ 0.57 % (p =0.000); CHOL: 205.9 $\pm$ 30.1 vs 186.12 $\pm$ 22.26 mg/dl, (p = 0.000); TG: 230.4 $\pm$ 48.1 vs 166.2 $\pm$ 31.82 (p = 0.000)]. In comparison between two groups, Group 1 had found to be significantly better glycemic control compared to their counterpart at the end of 6 months [( Group 1 vs Group 2, g, Mean $\pm$ SD) FBG: 6.37 $\pm$ 0.56 vs 6.98 $\pm$ 1.2; (p=0.024); ABF: 8.34 $\pm$ 0.84 vs 9.1 $\pm$ 1.46; (p=0.022);], serum cholesterol, TG, and ALT levels were also found to be significant change [ ( Mean  $\pm$  SD ) CHOL: 178.89 $\pm$ 18.59 vs 195 $\pm$ 23.55 mg/dl, (p = 0.010); TG: 155.85 $\pm$ 20.99 vs 178.91 $\pm$ 38.24 mg/ dl, (p =0.010); ALT: 55 $\pm$ 17.49 vs 45.74 $\pm$ 12.63 u/L, (p = 0.000);]. USG finding also found to be significantly reverse to normal from fatty changes in patients (77.7%) with both metformin and pioglitazone group than (18.8%) patients on metformin alone (p = 0.00) which all were fatty changes initially.

**Conclusion:** Treatment of NAFLD in newly detected Type 2 DM or IGT patients with high ALT by both metformin and pioglitazone is more effective in reduction of ALT and lipids and also able to reverse the severity of fatty changes of liver towards normal significantly.

## 1233

### Low cardiovascular (CV) risk hazard ratio observed with linagliptin in type 2 diabetes: further insights from a pre-defined CV meta-analysis

D. Neubacher<sup>1</sup>, O.-E. Johansen<sup>2</sup>, M. von Eynatten<sup>2</sup>, S. Patel<sup>3</sup>, H.-J. Woerle<sup>2</sup>;  
<sup>1</sup>Boehringer Ingelheim, Biberach, Germany, <sup>2</sup>Boehringer Ingelheim, Ingelheim, Germany, <sup>3</sup>Boehringer Ingelheim, Bracknell, UK.

**Background and aims:** Incidence of cardiovascular (CV) events is increased in type 2 diabetes (T2D) but the potential for CV risk modulation with glucose lowering is debated. Linagliptin, a DPP-4 inhibitor, provides a meaningful reduction in hyperglycaemia and also may have potential CV benefits. To further explore potential mechanisms behind this, we report additional relevant data from a large CV meta-analysis of linagliptin trial data.

**Materials and methods:** In this pre-specified meta-analysis from 8 Phase 3 randomised, controlled trials, CV events were prospectively adjudicated by a blinded independent expert committee. A composite primary endpoint of CV death, MI, stroke, and hospitalisation for unstable angina pectoris (UAP) was used. Results are given as hazard ratio (HR) for time to first occurrence of any components of the primary endpoint using a Cox regression model for linagliptin vs total comparators with factors of study (grouped by design), treatment (linagliptin vs combined comparators), gender (female vs male), race (Asian vs White), and time since T2D diagnosis (>5 vs  $\leq$ 5 yr). Comparative data for conventional CV risk factors across treatment groups are reported descriptively.

**Results:** 3319 patients received linagliptin once daily (5 mg: 3159, 10 mg: 160) and 1920 comparator (placebo: 977, glimepiride: 781, voglibose: 162). The overall study cohort (N=5239) seemed representative of a general T2D population among which overall HR was higher in patients with longer dura-

tion of T2D (1.51 [95% CI: 0.75–3.04]) and reduced in females (0.36 [95% CI: 0.16–0.84]) and Asians (0.28 [95% CI: 0.10–0.82]). A significantly reduced risk for the primary endpoint after treatment with linagliptin was indicated by the HR (0.36 [95% CI: 0.17–0.74]). Between-group changes in cholesterol and systolic and diastolic blood pressure were similar for linagliptin- and comparator-treated patients. Linagliptin treatment was associated with a greater reduction in HbA1c ( $-0.6 \pm 0.9\%$ ), fasting triglycerides ( $-11 \pm 136$  mg/dL), and no weight gain ( $0.01 \pm 3.09$  kg) in contrast to the total comparators (respectively  $-0.3 \pm 1.0\%$ ,  $-6 \pm 156$  mg/dL, and  $0.6 \pm 3.42$  kg).

**Conclusion:** Additional Cox regression analyses support the CV safety profile of linagliptin in a large phase III CV meta-analysis. The low CV HR observed with linagliptin cannot be fully explained by classical CV risk factors such as blood pressure and lipids. Further clinical outcome and mechanistic studies are underway to provide additional insights.

## 1234

### Zofenopril and ramipril plus ASA in post-myocardial infarction patients with left ventricular systolic dysfunction: a SMILE-4 Study retrospective analysis in diabetics

C. Borghi, E. Ambrosioni;  
Internal Medicine, Policlinico S. Orsola, Bologna, Italy.

**Background and aims:** Combination of an angiotensin-converting enzyme inhibitor (ACEI) and acetyl salicylic acid (ASA) is a common option in patients with both heart failure and ischemic heart disease. However, the well-known pharmacological interaction between ACEI and ASA may be responsible for a reduction of the positive effect of ACEI on cardiovascular outcomes. In the SMILE-4 Study we have shown a more favorable impact of zofenopril + ASA than ramipril + ASA combination on 1-year occurrence of major cardiovascular events in patients with acute myocardial infarction (AMI) complicated by left ventricular dysfunction (LVD). The objective was to compare zofenopril and ramipril efficacy in combination with ASA in a subgroup of patients of the SMILE-4 with and without a history of diabetes mellitus at the time of enrolment in the study.

**Materials and methods:** The SMILE-4 was a phase IIIb, randomized, double-blind, parallel-group, multicenter, European study comparing the safety and efficacy of zofenopril 60 mg/day and ramipril 10 mg/day plus ASA 100 mg/day, in patients with LVD (clinical signs of heart failure or a left ventricular ejection fraction or LVEF <45%) following AMI. The primary study endpoint was 1-year combined occurrence of death or hospitalization for cardiovascular causes. Information diabetes at baseline was available in 693 out of the 716 patients of the intention-to-treat population.

**Results:** In the main study population the primary outcome was significantly reduced by zofenopril vs. ramipril (odds ratio, OR and 95% confidence interval, CI: 0.70, 0.51–0.96; p=0.028). Overall, 131 (18.9%) patients suffered from and 562 (81.0%) were free from diabetes mellitus. The rate of major cardiovascular events was slightly, but not significantly, lower under zofenopril than under ramipril in diabetics (30.9% vs. 41.3%; OR: 0.64, 0.31–1.30; p=0.216). In the group of patients without diabetes the hazard reduction was almost significantly in favor of zofenopril (27.9% vs. 34.9% ramipril; OR: 0.72, 0.50–1.03; p=0.072). The reduction in the risk of major cardiovascular events was similar in patients with and without diabetes (p=0.925).

**Conclusion:** This retrospective analysis of the SMILE-4 Study confirmed the good efficacy of zofenopril plus ASA in the prevention of long-term cardiovascular outcomes also in the subgroup of patients with diabetes mellitus.

## 1235

### Effects of extended-release niacin/laropiprant (ERN/LRPT) on apolipoprotein (apo) B, LDL-cholesterol, and non-HDL-cholesterol targets in patients with type 2 diabetes

Y. Mitchell<sup>1</sup>, E. Brinton<sup>2</sup>, J. Triscari<sup>1</sup>, E. Chen<sup>1</sup>, A.O. Johnson-Levonas<sup>1</sup>, R. Ruck<sup>1</sup>, A. MacLean<sup>1</sup>, D. Maccubbin<sup>1</sup>;

<sup>1</sup>Merck Sharp & Dohme, Whitehouse Station, <sup>2</sup>Utah Foundation for Biomedical Research, Salt Lake City, USA.

**Background and aims:** ApoB is a good predictor of coronary risk especially in patients with type 2 diabetes (T2DM) and/or high triglycerides (TGs).

**Materials and methods:** This post-hoc analysis of a 36-week study evaluated apoB:LDL-C and apoB:non-HDL-C correlations in T2DM patients (n=796) randomized (4:3) to double-blind ERN/LRPT or placebo. After 4 weeks of treatment with 1 g/d, the ERN/LRPT dose was doubled to 2 g/d through study end. Patients had LDL-C  $\geq 1.55$  and  $< 2.97$  mmol/L and TG  $< 5.65$  mmol/L following a 4-week lipid-modifying run-in. Approximately 78% of patients were taking statins at baseline. Simple linear regression analyses calculated LDL-C and non-HDL-C levels corresponding to apoB value of 0.9 g/L at baseline and Week 12 in the overall population and patients with or without high TG (ie, baseline TG  $<$  and  $\geq 2.26$  mmol/L).

**Results:** LDL-C and non-HDL-C were well correlated with apoB at baseline and Week 12 in both treatment groups. At baseline and Week 12, predicted LDL-C and non-HDL-C values were lower than the minimum recommended goals of 2.59 and 3.36 mmol/L, respectively. When analyses were examined by baseline TG, predicted LDL-C values were significantly lower in high TG vs low TG patients (95% CIs did not overlap) at baseline and Week 12 for both treatment groups. Predicted non-HDL-C values were significantly higher in high TG vs low TG patients at baseline but not Week 12.

**Conclusions:** Irrespective of treatment with ERN/LRPT or placebo, more intensive LDL-C and non-HDL-C goals should be achieved in T2DM pts with and without hypertriglyceridemia to reach an apoB target  $\leq 0.9$  g/L.

Treatment Group	N*	apoB:LDL-C Pearson Correlation Coefficient (95% CI)	Predicted LDL-C (mmol/L) at apoB=0.9 g/L (95% CI)	apoB:non-HDL-C Pearson Correlation Coefficient (95% CI)	Predicted non-HDL-C (mmol/L) at apoB=0.9 g/L (95% CI)

\*Number of patients with paired apoB and LDL-C as well as apoB and non-HDL-C measurements

with LDL-C  $\geq 70$  and  $\leq 160$  mg/dl. The percent change in LDL-C and other lipids was estimated within each subgroup separately using a constrained longitudinal data analysis model with terms for treatment, time, time-by-treatment interaction, stratum, and time-by-stratum interaction. Safety was also assessed.

**Results:** In obese subjects, percent changes in LDL-C and other lipids were greater with EZ/Simva compared with doubling the baseline statin dose or switching to rosuvastatin, except HDL-C and Apo A-I. In non-obese subjects, percent changes in LDL-C, total cholesterol non-HDL-C, Apo B and Apo A-I were greater with EZ/Simva compared with doubling the baseline statin dose or switching to rosuvastatin. Also in non-obese subjects, treatment with EZ/Simva resulted in greater reductions in triglycerides compared with rosuvastatin and greater changes in HDL-C vs doubling the baseline statin dose. (Table) There were no clinically significant safety concerns in any of the treatment subgroups.

**Conclusion:** Regardless of baseline BMI, in this population of high risk diabetic subjects, switching to ezetimibe/simvastatin 10/20 was more effective at reducing LDL-C, total cholesterol and Apo B compared with doubling the baseline statin dose to simvastatin 40 mg or atorvastatin 20 mg or switching to rosuvastatin 10 mg. The safety and tolerability profiles were generally similar between treatment groups.

### Consistency of effect of ezetimibe/simvastatin compared with intensified lipid-lowering treatment strategies in obese and non-obese diabetic subjects

J.B. Rosen<sup>1</sup>, J.G. Jimenez<sup>2</sup>, V. Pirags<sup>3</sup>, H. Vides<sup>4</sup>, R. Massaad<sup>5</sup>, M.E. Hanson<sup>6</sup>, P. Brudi<sup>6</sup>, J. Triscari<sup>6</sup>

<sup>1</sup>Clinical Research of South Florida, Coral Gables, USA, <sup>2</sup>Hospital CIMA San Jose, Escazu, Costa Rica, <sup>3</sup>University of Latvia, Riga, Latvia, <sup>4</sup>Viljandi Hospital, Vildjandimaa, Estonia, <sup>5</sup>MSD Belgium, Brussels, Belgium, <sup>6</sup>Merck Sharp & Dohme Corp., Whitehouse Station, USA.

**Background and aims:** Diabetes is commonly associated with the presence of obesity and both conditions increase the risk of cardiovascular disease (CVD) and CVD events. The objective of this analysis was to assess the consistency of treatment effect of switching to ezetimibe/simvastatin 10/20 mg vs doubling the baseline statin dose (to simvastatin 40 mg or atorvastatin 20 mg) or switching to rosuvastatin 10 mg in subgroups of obese diabetic subjects (n=466) and non-obese diabetic subjects (n=342) based on body mass index (BMI)  $< 30$  kg/m<sup>2</sup> or  $> 30$  kg/m<sup>2</sup>.

**Materials and methods:** This was a post hoc analysis of a randomized, double-blind, 6-week study of adults 18-79 years with CVD and diabetes mellitus

#### Arterial stiffness is negatively related to insulin sensitivity in young type 1 diabetic patients

I. Pietrzak, W. Fendler, B. Mianowska, A. Zmysłowska, W. Młynarski, A. Szadkowska;

Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Poland.

**Background and aims:** Complications are the main reason of premature death in patients with diabetes mellitus. Increased arterial stiffness is observed even in young diabetic patients. Insulin resistance is one of the most important risk factors for cardiovascular diseases. The aim of the study was to determine the relationship between ambulatory arterial stiffness index (AASI) value and insulin sensitivity adolescents with type 1 diabetes.

**Materials and methods:** Eighty eight patients (52 males), aged  $16.1 \pm 2.4$  years, with an average diabetes duration of  $4.6 \pm 3.9$  years and without any evidence of arterial hypertension were recruited. AASI value was determined based on 24-hour automatic blood pressure monitoring results. Euglycemic - hyperinsulinemic clamp was performed to estimate insulin sensitivity. Glucose disposal rate (M value) determined during the last 30 min of the test was calculated as a surrogate of insulin resistance. Height, weight, waist circumference were measured and body mass index (BMI) were calculated. HbA1c and lipids were measured.

**Results:** Mean AASI equalled  $0.24 \pm 0.19$ . In univariate analysis AASI showed significant, positive correlation with BMI-Z score ( $r=0.23$ ,  $p=0.034$ ) and negative correlation with M value ( $r=-0.31$ ,  $p=0.005$ ). No correlations between AASI and patients' sex, diabetes duration, waist-Z score and HbA1c were found. Positive correlations with age and LDL cholesterol level were noted but did not reach statistical significance. Multivariate regression analysis showed that M value was the only factor which significantly correlated with AASI values.

**Conclusion:** In young type 1 diabetic patients arterial stiffness is negatively related to insulin sensitivity. Thus, insulin resistance may be considered as a risk factor for early macrovascular complications in type 1 diabetic patients.

### 1238

#### Metabolic syndrome and related components predict increased arterial stiffness (AS) in youth with type 1 diabetes: the SEARCH CVD study

D. Dabelea<sup>1</sup>, J. Talton<sup>2</sup>, R.F. Hamman<sup>1</sup>, R. D'Agostino Jr.<sup>2</sup>, R.P. Wadwa<sup>3</sup>, E. Urbina<sup>4</sup>, L. Dolan<sup>5</sup>, S. Daniels<sup>6</sup>, S. Marcovina<sup>7</sup>;

<sup>1</sup>Epidemiology, Colorado School of Public Health, Aurora, <sup>2</sup>Wake Forest School of Medicine, Winston Salem, <sup>3</sup>Pediatrics, Barbara Davis Center, Aurora, <sup>4</sup>Cincinnati Children's Hospital, <sup>5</sup>Pediatrics, Cincinnati Children's Hospital, <sup>6</sup>Pediatrics, University of Colorado School of Medicine, Aurora, <sup>7</sup>Medicine, University of Washington, Seattle, USA.

**Background and aims:** Adults with childhood onset type 1 diabetes (T1D) are at increased risk of premature cardiovascular disease (CVD). Yet, the natural history, the risk factors for premature CVD, and the progression from preclinical to advanced disease have not been studied systematically. In adults, markers of sub-clinical CVD such as increased pulse wave velocity (PWV) were shown to predict all cause and CVD mortality. We explored the rate of change and the role of CVD risk factors in predicting changes in PWV, a measure of arterial stiffness (AS), in youth with T1D, free of clinically diagnosed CVD.

**Materials and methods:** SEARCH CVD is an ancillary study to the SEARCH for Diabetes in Youth, a multicenter study that conducts population-based ascertainment of physician diagnosed diabetes in youth. PWV (meters/sec) in the carotid-femoral segment was measured with the SphygmoCor device. Higher PWV indicates increased central AS. CVD risk factors [triglycerides (TG), HDL-, LDL-cholesterol, waist circumference (WC), blood pressure, albumin/creatinine ratio (ACR), hemoglobin A1c (A1c) and metabolic syndrome (MetS: at least 2 risk factors, including high waist, TG, BP, low HDL-c)] were measured using standard protocols. Linear mixed models were used to model the rate of change in log-transformed PWV over time and explore significant predictors.

**Results:** There were 298 youth with T1D who had repeated measures of PWV and CVD risk factors approximately 5 years apart. At baseline, mean age was 14.5 yrs (SD 2.8), duration was 4.8 yrs (SD 3.8), and 87.6% were non-Hispanic white. At follow-up, average duration of T1D was 10.1 (SD 3.9) years. Over the follow-up period, PWV increased from 5.2 to 5.9 m/sec, an average annual change of 2.8% ( $p<0.0001$ ). In models adjusted for age, sex, and race/ethnicity, the presence of MetS at baseline was associated with a 1.07% higher increase in PWV ( $p=0.0035$ ), indicating a significantly faster stiffening of central arteries in youth with T1D and MetS, as compared to those without MetS. Individual components of the MetS, specifically WC ( $p<0.0001$ ), TG levels ( $p=0.029$ ) systolic ( $p<0.0001$ ) and diastolic BP z-scores ( $p<0.0001$ ), were also associated with increase in PWV. The effects were similar across the entire distribution of these CVD risk factors. In contrast, baseline HDL-c and LDL-c, ACR and A1c did not predict change in PWV. Moreover, an increase in WC ( $p<0.0001$ ), LDL-c ( $p=0.0095$ ) and TG levels ( $p=0.048$ ) over time were also associated with higher rate of change in PWV.

**Conclusion:** Our results show that youth with T1D and relatively short duration of diabetes have a significant increase in PWV over only 5 years. Nevertheless, the impact of this increase on later CVD morbidity and mortality is not currently known. The increase in PWV was predicted by presence of MetS and related components, especially central obesity and dyslipidemia. It is important to learn whether reducing MetS and its' components early in life will slow the progression of AS and reduce the burden of CVD in people with T1D.

#### Activated complement C3 (C3a) is cross-sectionally associated with carotid intima-media thickness and inversely with the ankle-arm blood pressure index: the CODAM study

E. Hertle<sup>1</sup>, M.M. van Greevenbroek<sup>1</sup>, C.J. van der Kallen<sup>1</sup>, S.L. Geijselaers<sup>1</sup>, I. Ferreira<sup>1,2</sup>, E.J. Feskens<sup>3</sup>, C.G. Schalkwijk<sup>1</sup>, C.D. Stehouwer<sup>1</sup>;

<sup>1</sup>CARIM School for Cardiovascular Diseases and Dept. of Internal Medicine, Maastricht University, <sup>2</sup>Dept. of Clinical Epidemiology and Medical Technology Assessment (KEMTA), Maastricht University Medical Centre, <sup>3</sup>Division of Human Nutrition, Section Nutrition and Epidemiology, Wageningen University, Netherlands.

**Background and aims:** Macrovascular atherosclerotic disease is a serious diabetic complication that involves inflammatory and immunological pathomechanisms. The central complement component C3 has been implicated in the development of metabolic and cardiovascular disease (CVD). C3a, an anaphylatoxin generated upon C3 activation, can induce multiple proinflammatory effects and may, as such, contribute to atherosclerosis. The study aim was to investigate the association of C3a with prevalent CVD and subclinical markers of atherosclerosis, i.e. carotid intima-media thickness (cIMT) and ankle-arm blood pressure index (AAIx) in a cohort of individuals at high-risk for type 2 diabetes (DM2) and CVD.

**Materials and methods:** The conducted cross-sectional analyses among 521 individuals (61% men, mean $\pm$ SD age of  $59.5 \pm 6.9$  years, 23% with impaired glucose metabolism and 23% with DM2) from the Cohort on Diabetes and Atherosclerosis Maastricht (CODAM) Study. Prevalent CVD was defined on the basis of self-reports, signs of myocardial infarction on an ECG and an AAIx $<0.9$ ; cIMT was measured by ultrasonography and AAIx by Doppler ultrasound. Associations between C3a and study outcomes were analysed with multiple logistic or linear regression analyses and all analyses were adjusted first, for age and sex, and further for glucose metabolism status, waist, blood lipids, blood pressure, renal function, physical activity, smoking, use of medication and C3, the precursor of C3a. We included additional adjustments for HOMA2-IR, and low-grade inflammation (LGI; expressed as a score calculated from 6 inflammatory markers) to ascertain whether these could explain part of the observed associations.

**Results:** The prevalence of CVD was 27%, cIMT was  $0.77 \pm 0.15$  mm, AAIx was  $1.10 \pm 0.13$  and median [IQR] of plasma C3a was 59 [50-73] ng/ml. Plasma C3a (per doubling) was associated with CVD [age and sex adjusted OR=1.55 (95%CI: 0.99-2.40),  $p=0.053$ ], but this association was not independent of other covariates [OR=0.94 (0.55-1.61),  $p=0.821$ ]. In contrast, higher levels of C3a were significantly associated with higher cIMT [ $\beta=0.033$  mm, (95% CI: 0.004; 0.063),  $p=0.028$ ] and lower AAIx [ $\beta=-0.033$ , (-0.056; -0.010),  $p=0.004$ ]. The associations with AAIx but less so with cIMT were partly explained by LGI [-0.007 (95%CI: -0.015; -0.001) and 0.004 (-0.003; 0.012), respectively], but not by HOMA2-IR.

**Conclusion:** Plasma C3a was independently associated with higher cIMT and lower AAIx, both supporting a role of activated complement in atherosclerosis. The lack of association with CVD might be explained by the concept that CVD comprises not only atherosclerosis/stenosis but also atherothrombosis and hypofibrinolysis and therefore may represent atherosclerosis less specifically than cIMT or AAIx. The independent association with subclinical atherosclerosis but not with CVD suggests that C3a may be primarily involved in atherogenesis, but to a lesser extent in processes that result in plaque rupture and atherothrombotic events.

### Arterial elastic wall properties are impaired early in the development of insulin resistance

V.A. Lambadiari<sup>1</sup>, I. Ikonomidis<sup>2</sup>, F. Spanoudi<sup>1</sup>, F. Kousathana<sup>1</sup>, C. Koukoulis<sup>2</sup>, G. Matsagouras<sup>1</sup>, N. Kadoglou<sup>2</sup>, H. Triantafyllidis<sup>2</sup>, M. Varoudi<sup>2</sup>, V. Tritakis<sup>2</sup>, M. Anastasiou-Nana<sup>2</sup>, J. Lekakis<sup>2</sup>, G. Dimitriadis<sup>1</sup>;

<sup>1</sup>2nd Dpt of Internal Medicine, Research Institute and Diabetes Center, <sup>2</sup>2nd Cardiology Department, Attikon University Hospital, Athens University Medical School, Greece.

**Background and aims:** Studies link insulin resistance with increased arterial stiffness. Arterial stiffness is associated with increased risk for cardiovascular disease. We investigated whether first degree relatives of diabetic patients have similarly impaired arterial wall properties with patients with diabetes as assessed after an oral glucosetolerance test (OGTT).

**Materials and methods:** 60 subjects underwent a standard 75-gr oral glucose tolerance test (OGTT) and plasma glucose and insulin levels were measured at 0, 30, 60, 90 and 120min after glucose loading. At the same time intervals, the carotid-femoral pulse-wave velocity (PWVc) was measured, using the Complior apparatus and aortic PWV (PWVa) and augmentation index (AI), using an oscillometric method (Arteriograph). Insulin resistance was assessed: a) in the fasting state, using homeostatic model assessment (HOMA) and hepatic insulin sensitivity-Index (HIS) b) postchallenge, using Matsuda index and insulin sensitivity index (ISI 0-120).

**Results:** Of the 60 subjects 20 were first degree relatives of type 2 diabetic patients and had normal OGTT (relatives), 20 had normal OGTT and no family history of diabetes (controls), and 20 were classified as diabetic (DM). Compared to controls, DM and relatives had both higher baseline PWVc (10.4±2.6 vs. 9.1±1.3 vs 8±1.5 m/sec, p<0.05), PWVa (9.1±2 vs. 8.9±2 vs. 7.3±1.6 m/sec, p<0.05), AI (24.5±9 vs. 24.2±14, 18±15%, p<0.05), insulin (14±6 vs. 15±4 vs. 10±4 µU/ml, p<0.05), HOMA, (3.9±2.1 vs. 3.6±1.6 vs. 2.4±1, p<0.05) and lower HIS (0.32±0.24 vs. 0.33±0.24 vs. 0.48±0.18, p<0.05), ISI (50±24 vs. 73±22 vs 93±17 mg.L<sup>2</sup>/mmol/mU/min, p<0.05), Matsuda index (3.1±1.6 vs. 3.0±1.6 vs. 5.3±1.2, p<0.05). Age, sex and BMI were similar between subgroups (p=ns). Compared to baseline, AI was reduced at 30 min by 30% in controls and relatives (p<0.01) but only 6% in diabetics (p=0.5). Conversely compared to baseline, insulin levels were increased at 30 min, to 54 µU/ml (484%) in controls, 56 µU/ml (266%) in DM and 110 µU/ml (681 %) in relatives (p<0.01). In all subjects, the % decrease in AI at 30 min was related to the corresponding % increase in insulin levels (r=-0.46, p<0.05).

**Conclusion:** First degree relatives and diabetic subjects have increased arterial stiffness and abnormal wave reflection compared to those with normal OGTT and no family history of diabetes. Controls and relatives show an acute decrease in AI related to the corresponding increase in insulin level likely because of insulin stimulation of endothelial cell nitric oxide (NO) synthesis. However relatives succeed this effect by raising their insulin levels nearly twice as those of normal subjects suggesting the onset of insulin resistance as confirmed by estimated indices of insulin resistance. In diabetic subjects the effect of insulin on AI is blunted likely because of severe insulin resistance.

## 1241

### Association of pulse wave velocity with cardiac autonomic neuropathy in patients with type 2 diabetes

S. Chorepsima<sup>1</sup>, I. Moysakakis<sup>2</sup>, D. Papadogiannis<sup>1</sup>, A. Kokkinos<sup>1</sup>, A. Protogerou<sup>1</sup>, N. Katsilambros<sup>1</sup>, N. Tentolouris<sup>1</sup>;

<sup>1</sup>1st Department of Propaedeutic Medicine, <sup>2</sup>Department of Cardiology, Laiko General Hospital, Athens, Greece.

**Background and aims:** Arterial stiffness is significantly increased in diabetes, regardless of the presence or absence of complications of the disease. Pulse

wave velocity (PWV) is considered as the gold-standard measurement to assess arterial stiffness. Limited data exist on the relationship between PWV and cardiac autonomic function in patients with type 2 diabetes (T2D). The aim of this cross-sectional study was to examine the association between PWV and indices of cardiac autonomic nervous function in patients with T2D.

**Materials and methods:** A total of 194 subjects with T2D were studied. PWV of the carotid-femoral segment was determined by applanation tonometry. Patients were classified as having normal and abnormal PWV according to age-corrected published recommendations. Short-term analysis of the heart rate variability (HRV) was performed in all subjects using the computer-aided examination and evaluation system VariaCardio TF4, whereas baroreflex sensitivity (BRS) was assessed in all subjects by the spontaneous sequence method using the BaroCor System. In addition, demographic and anthropometric data were obtained and lipids, renal function and HbA1c were measured.

**Results:** Patients with normal PWV (n=145) and patients with abnormal (n=49) PWV did not differ significantly in terms of age, sex, duration of diabetes, HbA1c values, renal function, lipid profile, smoking habits and prevalence of macrovascular complications as well as of retinopathy and microalbuminuria, while peripheral neuropathy was more common in the group of subjects with abnormal PWV (p=0.016). Patients with abnormal PWV had higher mean blood pressure (MP) than those with normal PWV (p=0.003). The total power (TP) of the HRV and the power of the high frequency (PHF) were lower in patients with abnormal PWV [125.8 (48.3-426.8) vs. 273.2 (111.5-571.1) ms<sup>2</sup>, p=0.006 and 39.0 (16.0-165.4) vs. 115.1 (42.9-252.0) ms<sup>2</sup>, p=0.002, respectively]. The power of the low frequency (PLF) and the PLF/ PHF ratio were not different between the two groups, while all time domain parameters of HRV like NN (p=0.040), SDNN (p=0.029) and MSDD (p=0.003) were significantly lower in patients with abnormal PWV. BRS was not significantly different between participants with normal and abnormal PWV [5.76 (4.11-8.53) ms/mmHg vs. 4.88 (3.18-7.19), p=0.146]. Univariate logistic regression showed that higher MP, presence of retinopathy and peripheral neuropathy as well as lower log values of PLF, PHF, TP, NN, SDNN and MSDD were associated with higher odds of abnormal PWV. Moreover, no significant associations were found between age, gender, BRS, glycaemic control, lipid profile, macrovascular complications or smoking status with PWV. Multivariate analysis, after adjustment for the effect of age, gender, duration of diabetes and MP, demonstrated that the odds [OR (95% confidence intervals)] of abnormal PWV increased significantly with lower log values of PHF [2.32 (1.27-4.24), p= 0.006], PLF [1.77 (1.00-3.14), p= 0.050], TP [2.22 (1.17-4.23), p= 0.015] and MSDD [2.23 (1.22-4.06), p= 0.009], as well as with higher MP [1.04 (1.01-1.07), p=0.009].

**Conclusion:** Cardiac autonomic dysfunction, assessed by parameters of heart rate variability, is a significant and independent determinant of increased arterial stiffness in subjects with T2D.

## 1242

### Non-alcoholic fatty liver disease is associated with carotid intima-media thickness only in type 2 diabetic subjects with insulin resistance

Y.-W. Cho<sup>1</sup>, Y.-J. Choi<sup>2</sup>, S.-W. Park<sup>1</sup>, E.-J. Lee<sup>3</sup>, K.-B. Huh<sup>2</sup>;

<sup>1</sup>Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, <sup>2</sup>Huh's Diabetes Center and the 21st Century Diabetes and Vascular Research Institute, Seoul, <sup>3</sup>Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is commonly associated with insulin resistance, obesity, metabolic syndrome, and diabetes. Although a lot of studies suggest that NAFLD is independently associated with an increased risk of atherosclerotic diseases, this association is less clear in type 2 diabetic subjects. The aim of the present study was to investigate whether there is a difference in carotid atherosclerotic burden in type 2 diabetic subjects according to NAFLD and/or insulin resistance.

**Materials and methods:** This was an observational study performed in 4437 patients with type 2 diabetes, consecutively enrolled in our Diabetes Center, who have never been treated with thiazolidinediones. Liver and carotid ultrasounds were performed on each subject. Carotid atherosclerosis was defined as having a clearly isolated focal plaque or mean carotid intima-media thickness (C-IMT) ≥ 1.1 mm. Insulin sensitivity was directly assessed by a rate constant for plasma glucose disappearance (Kitt) using short insulin tolerance test and insulin resistance was defined as Kitt < 2.5 %/min.

**Results:** Among subjects without NAFLD (n=1211), 747 subjects had insulin resistance. In contrast, among the subjects with NAFLD (n=3226), 747

patients did not have insulin resistance. Age, duration of diabetes, fasting glucose and HbA1c were longer or higher in those with insulin resistance. BMI and waist circumference were higher in those with NAFLD compared to those without NAFLD. There were significant differences in mean C-IMT and frequency of carotid atherosclerosis between groups classified by insulin resistance within the same NAFLD strata. Especially, mean C-IMT was the highest in subjects with both NAFLD and insulin resistance ( $0.844 \pm 0.004$  [mean  $\pm$  S.E.] mm vs.  $0.786 \pm 0.008$ ,  $0.821 \pm 0.007$ , and  $0.807 \pm 0.006$  mm,  $P$  for trend  $< 0.001$ , respectively, in insulin sensitive subjects without NAFLD, insulin resistant subjects without NAFLD, and insulin sensitive subjects with NAFLD). An augmentative effect of NAFLD and insulin resistance on mean C-IMT remained significant after adjusting for potential confounders; age, sex, duration of diabetes, various vascular diseases, hypoglycemic or anti-hypertensive agents, and BMI. However, mean C-IMT in subjects having either NAFLD or insulin resistance was not higher compared to that in those having neither NAFLD nor insulin resistance. And, the relationship between NAFLD and/or insulin resistance and the frequency of carotid atherosclerosis disappeared after adjustment.

**Conclusion:** In subjects with type 2 diabetes, having either NAFLD or insulin resistance is not associated with carotid atherosclerotic burden. However, having both NAFLD and insulin resistance seem to be a determinant factor associated with C-IMT.

## 1243

### Association between pulse pressure and cardiovascular risk in diabetes mellitus: a meta-analysis

C. Horikawa<sup>1</sup>, S. Kodama<sup>1</sup>, Y. Heianza<sup>1</sup>, S. Yoshizawa<sup>1</sup>, K. Fujihara<sup>1</sup>, S. Tanaka<sup>2</sup>, K.T. Iida<sup>3</sup>, Y. Yachi<sup>1</sup>, Y. Ohashi<sup>4</sup>, H. Sone<sup>1</sup>

<sup>1</sup>Department of Endocrinology and Metabolism, University of Tsukuba Mito Medical Center, Mito, <sup>2</sup>Department of Clinical Trial Design and Management, Kyoto University Hospital, <sup>3</sup>Department of Lifestyle Medicine, Ochanomizu University, Tokyo, <sup>4</sup>Department of Biostatistic, Epidemiology and Preventive Health Sciences, University of Tokyo, Japan.

**Background and aims:** It is important to determine cardiovascular (CV) risk in relation to pulse pressure (PP) especially in diabetes mellitus (DM) because patients with DM have more rigid arteries than those without DM. However, the quantitative association between PP and CV risk has been heterogeneous among studies. Our aim of this meta-analysis is to estimate the strength of the association between PP and CV risk and to determine the reason for this heterogeneity.

**Materials and methods:** Electronic literature (up to Feb. 25, 2012) search was conducted for cohort studies reporting relative risk (RR) of cardiovascular disease (CVD), coronary heart disease (CHD), or stroke in relation to PP in patients with DM. The most fully adjusted RR for these outcomes in each study for each +10 mmHg increase in PP in DM was pooled with a random-effects model.

**Results:** Thirteen articles were included in this meta-analysis. RR (95% confidence interval [95%CI]) for a +10 mmHg increase in PP was 1.12 (1.04–1.20) for CVD (12 studies) (Figure), 1.18 (1.08–1.29) for CHD (5 studies), and 1.13 (1.07–1.19) for stroke (4 studies). In studies that concurrently assessed CV risk in relation to both PP and other blood pressure (BP) indexes such as systolic BP (SBP) (7 studies), diastolic BP (DBP) (8 studies), or mean aortic pressure (MAP) (4 studies), the pooled RR of CVD for a +10 mmHg increase in PP vs. other BP indexes was 1.09 vs. 1.06 for PP vs. SBP, 1.12 vs. 1.04 for PP vs. DBP, and 1.18 vs. 1.23 for PP vs. MAP. Stratified analysis indicated that the CVD risk for an incremental increase in PP was attenuated in studies adjusted for duration of diabetes ( $P=0.03$ ) or indicators of nephropathy ( $P=0.001$ ).

**Conclusion:** Higher PP is associated with elevated CV risk in patients with DM. However, the elevated risk may be due to DM itself or DM-specific complications rather than high PP. Evidence is insufficient for measuring PP in addition to SBP in diabetic patients.

Figure Forest plot with 95% confidence interval (95% CI) regarding relative risk (RR) of cardiovascular disease (CVD) for a +10 mmHg increase in pulse pressure (PP). The pooled RR is indicated by a diamond. Area of each square is proportional to study weight (i.e., inverse of variance).

## 1244

### First ever 24-hour central blood pressure in patients with type 1 diabetes

S. Theilade<sup>1</sup>, M. Lajer<sup>1</sup>, C. Joergensen<sup>1</sup>, F. Persson<sup>1</sup>, G. Andresdottir<sup>1</sup>, H. Reinhard<sup>1</sup>, S.E. Nielsen<sup>1</sup>, P. Lacy<sup>2</sup>, B. Williams<sup>2</sup>, P. Rossing<sup>1</sup>

<sup>1</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>2</sup>Department of Cardiovascular Sciences, University of Leicester, UK.

**Background and aims:** To investigate whether measurement of 24-hour ambulatory central aortic systolic pressure (CASP) using calibrated tonometry is feasible and associated with albuminuria in type 1 diabetes.

**Methods and materials:** Cross-sectional study, 649 Caucasian T1DM patients and 86 controls (C). Patients were 69 with short diabetes duration ( $<10$  years), normoalbuminuria ( $<30$ mg/24-hour) and not receiving antihypertensive treatment (SN); 211 with longstanding diabetes ( $\geq 10$  years) and normoalbuminuria (LN); 164 with microalbuminuria (30–300mg/24-hour) (Mi) and 205 with macroalbuminuria ( $>300$ mg/24-hour) (Ma). 24-hour ambulatory blood pressures were measured with tonometry by BPro (HealthStats, Singapore), previously validated according to ESH and AAMI. Dipping was percentage decrease in blood pressure (BP) from day- to nighttime (12pm–6am).

**Results:** For the groups (C, SN, LN, Mi, Ma): mean  $\pm$  SD age was  $49 \pm 12$ ;  $39 \pm 13$ ;  $57 \pm 11$ ;  $58 \pm 11$  and  $55 \pm 10$  years; diabetes duration: nil;  $6 \pm 6$ ;  $38 \pm 11$ ;  $36 \pm 15$  and  $39 \pm 11$  years; and eGFR:  $96 \pm 16$ ;  $107 \pm 21$ ;  $90 \pm 20$ ;  $85 \pm 26$ ; and  $62 \pm 29$  ml/min/1.73m<sup>2</sup>; ( $p < 0.001$  for all). Mean 24-hour CASP was  $114 \pm 17$ ;  $115 \pm 13$ ;  $121 \pm 13$ ;  $119 \pm 16$  and  $122 \pm 14$  mmHg; ( $p < 0.001$ ). Mean 24-hour systolic BP (SBP) was  $122 \pm 19$ ;  $124 \pm 15$ ;  $129 \pm 15$ ;  $128 \pm 17$  and  $132 \pm 15$  mmHg; ( $p < 0.001$ ). Central dipping was  $10.0 \pm 5.9$ ;  $11.1 \pm 7.9$ ;  $8.7 \pm 6.1$ ;  $8.9 \pm 6.6$  and  $6.6 \pm 6.6$ %; ( $p < 0.001$ ). Brachial dipping was  $10.6 \pm 5.2$ ;  $11.2 \pm 6.4$ ;  $9.5 \pm 5.3$ ;  $9.4 \pm 5.6$  and  $7.5 \pm 5.9$ %; ( $p < 0.001$ ). Correlations between BPs and dipping were  $r^2 = 0.98$  and  $r^2 = 0.93$  ( $p < 0.001$  and  $p < 0.001$ ). Following multivariate adjustment (age, gender, 24-hour mean arterial pressure, 24-hour heart rate, BMI) both CASP and SBP increased with diabetes duration and albuminuria ( $p < 0.001$ ). Systolic and central dipping decreased with duration and albuminuria ( $p = 0.012$  and  $p < 0.013$ ).

**Conclusion:** 24-hour CASP and brachial BP measurements were feasible in patients with type 1 diabetes. 24-hour CASP and brachial BPs increased, while brachial and less so central dipping decreased with diabetes duration and albuminuria, independently of covariates.

Clinical Trial Registration Number: NCT01171248

## 1245

**Carotid intima-media thickness is reduced 12 months after gastric bypass surgery in patients with type 2 diabetes**L. Lundby-Christensen<sup>1</sup>, L. Tarnow<sup>1</sup>, A. Vaag<sup>2</sup>, N. Wiinberg<sup>3</sup>, D. Hansen<sup>4</sup>, D. Worm<sup>4</sup>, L. Hvolris<sup>4</sup>, L. Naver<sup>4</sup>, T. Almdal<sup>1</sup>;<sup>1</sup>Steno Diabetes Center, Gentofte, <sup>2</sup>Rigshospitalet, Copenhagen,<sup>3</sup>Frederiksberg Hospital, <sup>4</sup>Hvidovre University Hospital, Denmark.

**Background and aim:** Patients with type 2 diabetes (T2D) have increased risk of cardiovascular disease (CVD). Whether normalised glycaemic control reduces this risk remains still unknown. Laparoscopic Roux-en-Y gastric bypass (RYGB) has been shown to improve or even normalise blood glucose in patients with T2D. RYGB is therefore a unique in vivo model to investigate potential changes in risk of CVD that follows improved glycaemic control. Carotid intima-media thickness (carotid IMT) measured by ultrasound is a well established marker of CVD. We aimed to investigate the effects of RYGB on the progression of carotid IMT in severely obese patients with and without T2D.

**Materials and methods:** Thirtyfour patients (hereof 16 with normal glucose tolerance (NGT) and 18 with T2D) were examined before and 6 and 12 months after RYGB. At all examinations mean and maximum carotid IMT of the common carotid artery were measured using B-mode ultrasound (GE logic 9 with a 9 linear (8 MHz) or 12 linear (12 MHz) probe. All dynamic sequences were stored and analysed afterwards using specialised software.

**Results:** All patients performed as expected a significant weightloss 12 months after RYGB (-29.8 kg,  $p < 0.01$  (T2D) and -30.6 kg,  $p < 0.01$  (NGT)). Among the T2D patients who prior to RYGB received glucose lowering drugs (either tablets and/or insulin), 80% of the patients could terminate this treatment and HbA1c decreased despite this with 0.66% ( $p < 0.01$ ). Mean carotid IMT decreased 0.041 mm among patients with T2D 12 months after RYGB ( $p > 0.01$ ) and decreased 0.010 mm among patients with NGT ( $p = 0.44$ ). The change in mean IMT was not significantly different in patients with and without T2D ( $p = 0.11$ ). Maximum carotid IMT decreased 0.070 mm 12 months after RYGB among patients with T2D ( $p > 0.01$ ) and decreased 0.041 mm ( $p = 0.02$ ) among patients with NGT. The change in maximum IMT was not significantly different in patients with and without T2D ( $p = 0.25$ ). Statistical analyses were performed using SAS statistics and the proc mixed procedure.

**Conclusion:** Significant reduction in mean carotid IMT was found in patients with T2D 12 months after RYGB but not among patients without T2D. However significant reduction in maximum carotid IMT was found both in patients with and without T2D 12 months after RYGB. Even though the changes in carotid IMT was more pronounced among patients with T2D, which could be due to the improved glycaemic control, the difference in patients with and without T2D was not significant.

## 1246

**Skin autofluorescence in type 1 diabetes mellitus**M. Genevieve<sup>1,2</sup>, C. Gonzalez<sup>3,2</sup>, A. Vivot<sup>4,2</sup>, C. Raffaitin<sup>3,2</sup>, H. Gin<sup>3,2</sup>, V. Rigalleau<sup>3,2</sup>;<sup>1</sup>Nephrologie, Hôpital Pellegrin, Bordeaux, <sup>2</sup>Université Bordeaux 2 Victor Segalen, Bordeaux, <sup>3</sup>Diabétologie-Nutrition, Hôpital Haut-leveque, Pessac,<sup>4</sup>Santé publique, Hôpital Pellegrin, Bordeaux, France.

**Background and aims:** Since skin autofluorescence can assess the subcutaneous accumulation of fluorescent advanced glycation end products, we investigated whether it was linked with glycaemic control and complications of type 1 diabetes mellitus.

**Materials and methods:** Using the AGE Reader™, we measured the forearm skin autofluorescence in 302 patients with type 1 diabetes: 174 men, age: 50 (37–61) years, diabetes duration: 21 (11–31) years, followed up every six months. We examined its association with their glucose control: last HbA1c and mean of the last five HbA1c. The skin autofluorescence values were compared in the patients with and without diabetic complications. The association between the skin autofluorescence and the glucose control were tested by linear regression analysis. The skin autofluorescence from subjects with or without complications were compared by non-parametric tests.  $P < 0.05$  was considered significant.

**Results:** The skin autofluorescence was 2.0 (1.7–2.4) arbitrary units (AU), correlated with age and diabetes duration (respectively  $r = 0.20$  and  $r = 0.15$ ,  $p < 0.0001$ ). After adjustment for age and diabetes duration, it was related to the 2–3 years ( $\beta = 0.13$ ,  $p = 0.0001$ ,  $r = 0.24$ ,  $n = 247$ ). Skin autofluorescence was

higher in the patients with severity of complications (no retinopathy  $n = 88$ , skin autofluorescence 2.2 (1.8–2.5) AU,  $p < 0.001$  versus others), proliferative retinopathy ( $n = 41$ , 2.5 (2–2.7) AU,  $p < 0.05$  versus background), macroalbuminuria ( $n = 10$ , 3.0 (2.5–3.9) AU,  $p < 0.001$  versus others), and macroangiopathy ( $n = 24$  previous cardiovascular event, 2.4 (2.0–2.7) AU,  $p < 0.005$  versus others). 3/5 patients had higher than theoretical skin autofluorescence, although their last HbA1c and diabetes duration were similar to the others, they had 2 to 3 times more severe microangiopathic complications.

**Conclusion:** Skin autofluorescence is related to long-term glucose control and diabetic complications.

### Inhibitory effect of irbesartan on HMGB1 production in macrophages

Y. Kato, K. Kato, H. Kamiya, A. Watarai, E. Naito, J. Nakamura;  
Division of Diabetes, Department of Internal Medicine, Diabetes Center,  
Aichi Medical University, Nagakute, Japan.

**Background and aims:** High-mobility group box 1 (HMGB1) is released into the extracellular space by activated macrophages and acts as an inflammatory mediator through the receptor for advanced glycation endproducts (RAGE) or toll-like receptor (TLR). Recent studies reported that the number of HMGB1-producing macrophages significantly increased in human atherosclerotic lesions and the serum HMGB1 concentrations were significantly increased in type 1 and type 2 diabetic patients, suggesting that HMGB1 plays an important role in the development of diabetic complications through inflammatory processes. Sub-study of Irbesartan in Patients with type 2 diabetes and Microalbuminuria (IRMA 2) demonstrated that irbesartan treatment reduced biomarkers of inflammatory activities in type 2 diabetic patients. However, the effects of irbesartan on HMGB1 production are still unknown. In the present study, we investigated the effects of irbesartan on HMGB1 production and the molecular mechanisms of its effects in macrophages to evaluate the anti-inflammatory effects of irbesartan.

**Materials and methods:** The murine macrophage cell line, RAW264.7 cells were maintained in RPMI 1640 medium containing 5% heat-inactivated fetal calf serum. RAW264.7 cells were stimulated by lipopolysaccharide (LPS) from *Escherichia coli* O55:B5. HMGB1 or interferon- $\beta$  (IFN- $\beta$ ) was measured by ELISA. Nitric oxide (NO) was measured as its end product, nitrite, using Griess reagent. The cell surface expression of TLR4 was examined by a flow cytometric analysis.

**Results:** Irbesartan inhibited LPS-induced HMGB1 production in RAW264.7 cells ( $101.9 \pm 9.6$  vs.  $36.9 \pm 8.1$  ng/mL,  $p < 0.005$ ). Irbesartan reduced LPS-induced IFN- $\beta$  production ( $162.7 \pm 0.7$  vs.  $58.4 \pm 1.3$  pg/mL,  $p < 0.01$ ). Irbesartan inhibited LPS-induced NO production ( $18.3 \pm 2.1$  vs.  $9.5 \pm 0.4$   $\mu$ M,  $p < 0.01$ ). Losartan did not inhibit LPS-induced HMGB1 production. Irbesartan did not affect the cell surface expression of TLR4.

**Conclusion:** We examined the effects of irbesartan on LPS-induced production of HMGB1, IFN- $\beta$ , and NO in macrophages. Previous studies indicated that LPS exploited TLR4/IFN- $\beta$  signaling pathway to induce HMGB1 release, and that NO played a role as a downstream molecule of IFN- $\beta$  signalling pathway. Irbesartan inhibited HMGB1 production via the inhibitory effect on IFN- $\beta$  signalling pathway in macrophages. Our data indicates that irbesartan would have beneficial effects on diabetic complications through its anti-inflammatory effects.

### Disturbed mitochondrial function can contribute to the metabolic side effects of olanzapine

A. Kolonics, Z. Literáti-Nagy, A. Hidasi, K. Tóty;  
Molecular Pharmacology, N-Gen Research Laboratories, Budapest,  
Hungary.

**Background and aims:** Second generation antipsychotics drugs commonly cause metabolic side effects including rapid development of insulin resistance. Antipsychotic drugs are active on several receptors and activation of hypothalamic AMPK through the histamine H1 receptor has been identified as a key mechanism of the orexigenic effect of antipsychotic drugs. Olanzapine has also a rapid effect on lipid metabolism resulting in inhibition of lipolysis and a switch in fuel preference. Mitochondrial abnormalities are causally linked to certain forms of diabetes, obesity and mental disorders. We analyzed the effects of olanzapine on mitochondrial function to clarify its involvement in pathogenesis of metabolic side effects.

**Materials and methods:** Direct effect of olanzapine on mitochondrial function was evaluated in mitoplast isolated from murine brain and heart. Complex I, II activity and succinate induced reverse electron flow was measured by Amplex Red in functionally intact mitochondria. The effects on mitochondrial ROS production in L6 muscle cells was revealed by MitoSox staining. In vivo effects of olanzapine were studied in mice after single 20 mg/kg i.p. and 10-day 3 mg/kg i.p. treatment. Olanzapine provoked insulin resistance was

studied in healthy individuals by hyperinsulinemic euglycemic clamp method and mitochondrial function in peripheral lymphocytes was evaluated by FACS analysis simultaneously. Molecular interaction between olanzapine and complex I was studied in silico by Vina docking program on complex I structure (Thermus Thermophilus).

**Results:** Daily 10 mg olanzapine resulted in a significant decrease of whole body insulin sensitivity ( $-32 \pm 5\%$ ) in healthy individuals for the 18th day. Analysis of lymphocytes revealed slight increase of mitochondrial mass (MitoTracker staining) and robust increase of ROS production (DCFDA:  $85 \pm 20\%$ ). In brain and heart derived mitoplast olanzapine directly inhibited complex I activity ( $50 \pm 2\%$ ) at high concentration (200–500  $\mu$ M). At therapeutically relevant dose-range (0.3–5  $\mu$ M) olanzapine elevated mitochondrial ROS production in L6 myocytes. In case of 1 h treatment slight increase of basal ROS production was detected in mitoplast isolated from mouse brain and muscle after 1h treatment. Succinate induced ROS production was elevated only in brain mitoplast, with an robust increase of complex I activity. Chronic 10 days olanzapine treatment resulted in weak inhibition of complex I and slight elevation of complex II activity in both types of tissues. Molecular docking analysis revealed binding of olanzapine to NADH binding site of Nqo1 subunit with comparable binding energy to NADH (dG= -8.6 kcal/mol).

**Conclusion:** Data indicate that olanzapine rapidly induced insulin resistance in healthy individuals that was associated with a change in mitochondrial function of peripheral lymphocytes. In silico docking revealed a potential binding of olanzapine on complex I. Olanzapine induced disturbance of mitochondrial function, the elevated ROS production a modulation of complex I activity may contribute to the metabolic side effects of the drug.

### High glucose effects on eNOS and SIRT1 expression and chromatin acetylation in endothelial cells

A. De Marco<sup>1,2</sup>, G. Formoso<sup>1,2</sup>, N. Di Pietro<sup>3,2</sup>, A. Pandolfi<sup>3,2</sup>, V. De Laurenzi<sup>3,2</sup>, M. Federici<sup>4</sup>, A. Consoli<sup>1,2</sup>;

<sup>1</sup>Department of Medicine and Aging, University of Chieti, <sup>2</sup>G. d'Annunzio University Foundation (CeSI), Chieti, <sup>3</sup>Department of Biomedical Sciences, University of Chieti, <sup>4</sup>Department of Internal Medicine, University of Rome Tor Vergata, Italy.

**Background and aims:** The “bad metabolic legacy” exposing to increased vascular risk diabetic individuals who experienced poor glycemic control in the early stages of the disease might be mediated by hyperglycemia related epigenetic modifications in the vascular cells. SIRT1 is an important regulator of metabolism and stress response. As an NAD<sup>+</sup>-dependent protein deacetylase, SIRT1 regulates gene expression programs in response to cellular metabolic status, modulating chromatin function via several epigenetic mechanisms such as direct deacetylation of histones, recruitment of other nuclear enzymes to chromatin or deacetylation of transcription factors and coregulators. Since increased eNOS expression and activity have been described among the hyperglycemia related endothelial cells modifications, we set to investigate eNOS, SIRT1 and chromatin epigenetic modifications (Histones H3 Lysine acetylation) following high glucose exposure in endothelial cells.

**Materials and methods:** HUVEC and HAEC were cultured in Normal Glucose (NG, 5 mmol/L) and High Glucose (HG, 25 mmol/L) conditions for 48 hours. eNOS and SIRT1 protein levels were assessed by Western Blot analysis. In order to evaluate the role of SIRT1 in modulating eNOS expression, HUVEC and HAEC were transfected by electroporation (Amaza<sup>®</sup> Nucleofector<sup>®</sup> Technology, LONZA) to over-express (SIRT1+) or down-regulate (SIRT1-) SIRT1 expression. Chromatin Immunoprecipitation was performed on transfected HAEC to analyze the acetylation levels of Histone H3 at eNOS promoter. Data are expressed as fold increase over NG condition ( $\pm$  Standard Deviation). Statistical analysis were performed using the One-Way ANOVA or Student *t*-test. Value of  $p < 0.05$  were considered statistically different.

**Results:** At the Western Blot analysis, as compared to the respective control cells, eNOS and SIRT1 protein levels were found to be increased by 30% ( $\pm 0.18$ ) and 38% ( $\pm 0.07$ ) respectively in HUVEC exposed to HG, and by 68% ( $\pm 0.038$ ) and 40% ( $\pm 0.13$ ) respectively in HAEC exposed to HG. In order to verify the effects of SIRT1 on eNOS expression, HUVEC and HAEC were transfected to over-express (SIRT1+) or down-regulate (SIRT1-) the expression of SIRT1. In HUVEC SIRT1+, eNOS resulted increased by 66% ( $\pm 0.3$ ) when cultured in NG and by 52% ( $\pm 0.21$ ) when cultured in HG. This increase was even larger in HAEC SIRT1, where it was of 2.6 folds when cells were cultured in HG and of 2.3 folds when cultured in NG. We performed Chromatin

Immunoprecipitation (ChIP) on transfected HAEC exposed to NG and HG for 48 hours to analyze Histone H3 acetylation levels at the eNOS promoter. As compared to NG HAEC, H3 acetylation level resulted higher ( $29\% \pm 0.17$ ) in the proximal promoter region (-166/-26 bp) in HAEC exposed to HG. In HAEC SIRT1+, H3 acetylation levels at distal promoter and proximal promoter regions were  $60\% (\pm 0.049)$  and  $97\% (\pm 0.07)$  greater than in control HAEC when both cultured in NG.

**Conclusion:** Taken together, these data suggest a possible role for SIRT1 in modulating the expression of eNOS in endothelial cells in response to metabolic stress like hyperglycemia and that such modulation could, at least in part, be mediated by epigenetic mechanisms.

## 1250

### The vascular protective effect of GLP-1 on HMVEC in hyperglycaemic conditions

D.-M. Lim<sup>1</sup>, K.-Y. Park<sup>1</sup>, B.-J. Kim<sup>1</sup>, J.-Y. Kim<sup>2</sup>;

<sup>1</sup>Endocrinology and Metabolism, Konyang university Hospital, Daejeon,

<sup>2</sup>Soonchunhyang Medical Science Research Institute, School of Medicine, Soonchunhyang University, Chunan, Republic of Korea.

**Background and aims:** The major complication of diabetes mellitus is cardiovascular problem. But the aspects of vascular complication are some different in macrovascular and microvascular features. So, this study was conducted to investigate the different response and mechanism of human microvascular endothelial cell (HMVEC) and human aortic endothelial cell (HAEC) in high glucose and in pretreatment with exendin-4 (Ex-4), a GLP-1 receptor agonist.

**Materials and methods:** Expression of the Notch-1, 4 and GLP-1 receptor was examined in HMVEC and HAEC by RT-PCR and western blot analysis. The different response of HMVEC and HAEC in high glucose (30 mM) after pretreatment with Ex-4 (25 nM) was evaluated based on real-time PCR, western blot analysis, immunocytochemistry, wound healing assay and angiogenesis assay. Also, we investigate the association with the different response of GLP-1 and the signaling of Notch-1 in HMVEC and HAEC using Notch-1 siRNA.

**Results:** GLP-1 receptor, notch 1 and 4 were expressed in HMVEC and HAEC. Although, there was no angiogenesis and wound healing effect in high glucose stressed HAEC and/or pretreatment with VEGF or Ex-4, but in HMVEC, angiogenesis and wound healing effect were shown. Also, Notch-1 signaling was changed in HMVEC. MMP-2, PECAM-1 and TIMP-2 were increase in HMVEC with pretreatment Ex-4. To investigate whether the angiogenesis effects of Ex-4 are related Notch-1, the effect of down-regulation Notch was examined using a siRNA method in HMVEC. Branch number of angiogenesis, wound healing effect and MMP-2 were significantly decreased in Notch-1 siRNA treated HMVEC.

**Conclusion:** Our findings suggested that regulation of Notch-1 signaling in Ex-4 treated HMVEC induce angiogenesis and wound healing effect. Modulation of Notch 1 signaling may hold promise as a novel therapeutic strategy for the treatment of diabetic microvascular complications.

## 1251

### Exendin-4 protected human umbilical vein endothelial cells from tunicamycin-induced apoptosis via inhibiting IRE1 $\alpha$ /JNK/caspase-3 pathway

L. Wu, L. Liu;

Department of Endocrinology, Fujian Institute of Endocrinology, Union Hospital of Fujian Medical University, Fuzhou, China.

**Background and aims:** The survival of endothelial cells is important to maintain the integrality of vascular structure and function. The unusual increase of apoptosis of endothelial cells is a significant factor for atherosclerosis. The goal of this study was to explore the effect of Exendin-4, a glucagon-like peptide-1 receptor agonist, on tunicamycin-induced apoptosis in human umbilical vein endothelial cells (HUVECs).

**Materials and methods:** All studies were performed in primary HUVECs treated with tunicamycin with or without Exendin-4 pretreatment. Markers of cell viability and apoptosis were assessed in all cells, as well as the protein expression levels of IRE1 $\alpha$ , p-IRE1 $\alpha$ , JNK, p-JNK and caspase-3.

**Results:** Following tunicamycin administration, HUVECs viability was gradually reduced in a dose- and time-dependent manner, and fluorescence microscopy confirmed that tunicamycin was inducing HUVEC apoptosis. This

apoptotic effect was attenuated by Exendin-4 pretreatment. The cell viability gradually increased with pretreatment of Exendin-4 (5–150 nmol/L), compared with tunicamycin-alone group. Fluorescence microscopic analysis with Hoechst/PI staining showed that the apoptotic rate of HUVECs decreased 40% in Exendin-4-pretreatment group than that of tunicamycin-alone group ( $P < 0.01$ ). Similarly, the ratio of p-IRE1 $\alpha$ /IRE1 $\alpha$ , p-JNK/JNK and active caspase-3/procaspase-3 were increased by tunicamycin (10  $\mu$ g/ml), an effect that was counteracted by Exendin-4. Pretreatment of HUVECs with exendin-4 resulted in a 23.25% decrease of the expression of p-IRE1 $\alpha$  than that of tunicamycin-alone group, and resulted in 29.25% and 22.2% decreases of p-JNK and active caspase-3, respectively ( $P < 0.01$ ). The effect of exendin-4 was similar to that of tauroursodeoxycholic acid (TUDCA). Compared with tunicamycin-alone group, the ratios of p-IRE1 $\alpha$ /IRE1 $\alpha$ , p-JNK/JNK and active caspase-3 /procaspase-3 were all reduced both in exendin-4-pretreatment group and TUDCA-pretreatment group.

**Conclusion:** This study demonstrates that Exendin-4 can protect HUVECs from tunicamycin-induced apoptosis. Furthermore, our data suggests that the mechanism for this effect is mediated by inhibiting the IRE1 $\alpha$ /JNK/caspase-3 pathway.

## 1252

### Metformin protects endothelial cells from methylglyoxal-mediated damage

E.J. Pilavachi, N. Murphy, J. Mabley;

School of Pharmacy and Biomolecular Sciences, University of Brighton, UK.

**Background and aims:** Methylglyoxal (MGO), a glycolysis derived reactive dicarbonyl compound has been implicated as a central mediator of diabetic complications in both type I and type II diabetes. MGO has already been shown to cause endothelial cell dysfunction via increased oxidative stress. Aminoguanidine is a known scavenger of MGO and can protect endothelial cell function from MGO-mediated damage. Metformin has a similar structure to aminoguanidine and has also been shown to be capable of scavenging MGO though not as effectively. The aim of this study is to investigate whether metformin is able to protect endothelial cell function from MGO-mediated dysfunction.

**Materials and methods:** The effects of MGO on acetylcholine-mediated NO dependent vasorelaxation were measured using ex vivo rat aortic rings exposed to 0.3 mM MGO for 4h, metformin (0.3 and 0.5 mM) was co-administered to investigate any protective effect. In vitro experiments using the EA.Hy926 human endothelial cell line were performed examining the effect of MGO  $\pm$  metformin on cell viability (MTT assay), necrosis and apoptosis levels (propidium iodide/Hoechst staining followed by morphological analysis) and cellular oxidative stress (NBT assay).

**Results:** MGO (0.3 mM) exposure increased the IC<sub>50</sub> for acetylcholine-mediated relaxation from  $0.06 \pm 0.01$   $\mu$ M to  $0.315 \pm 0.1$   $\mu$ M ( $P < 0.05$ ), with metformin at 0.25 and 0.5 mM reducing this to  $0.09 \pm 0.02$   $\mu$ M and  $0.06 \pm 0.01$   $\mu$ M respectively ( $p < 0.05$  vs. MGO alone). Metformin also protected the endothelial cell line from MGO-mediated loss of cell viability significantly increasing it from  $65 \pm 3\%$  with MGO 0.6 mM alone to  $90 \pm 2\%$  with 0.5 mM metformin ( $p < 0.05$  vs. MGO alone). MGO 0.3 mM increased both necrosis (from  $6 \pm 2\%$  to  $15 \pm 4\%$  ( $p < 0.05$ )) and apoptosis (from  $1.3 \pm 0.7\%$  to  $3.3 \pm 0.8\%$  ( $p < 0.05$ )) levels in endothelial cells. Metformin at 0.25 mM and 0.5 mM was again able to significantly protect against the MGO-mediated increase in cell death reducing necrosis to  $6.3 \pm 3\%$  and  $5 \pm 2\%$  and apoptosis to  $2.1 \pm 0.5$  and  $1.8 \pm 0.2$  respectively. Metformin was also able to reduce the levels of cellular oxidative stress observed following MGO exposure.

**Conclusion:** Metformin was able to provide significant protection against MGO-mediated endothelial cell dysfunction. Metformin also protected the endothelial cell line from MGO-mediated decrease in cell viability and increase in necrosis and apoptosis. This protective effect may be mediated by metformin scavenging MGO and hence preventing the increased cellular oxidative stress. These data suggest that metformin, apart from its glucose-lowering effect, may also provide direct protection to the cardiovascular system in diabetes.

## 1253

### Effect of sulfonylurea, glinide and insulinotropic imidazoline compounds on endothelial cell survival

S.V. Zaitsev, I.I. Zaitseva, P.-O. Berggren;

The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Hyperglycaemia induces dysfunction and damage of vascular endothelial cells leading to diabetic complications. The aim of this study was to investigate the effects of insulinotropic compounds (RX871024, efaroxan, glibenclamide, repaglinide) and elevated glucose on endothelial cells in the absence or presence of vascular endothelial growth factor (VEGF), which under normal conditions enhances endothelial cell proliferation, survival and nitric oxide (NO) production.

**Materials and methods:** Human umbilical vein endothelial cells (HUVEC) were cultured with the compounds at a high glucose concentration in the presence or absence of VEGF and viability, proliferation and NO production were measured. Cell viability was detected by using MTS tetrazolium compound after 9 days culture. Assessment of HUVEC proliferation was performed by measuring BrdU incorporation into the DNA of dividing cells for 90 h. NO production was measured as  $\text{NO}_2^-$  release into the medium by using Griess reagent after 40 h incubation.

**Results:** After culture at 25 mM glucose HUVEC viability was diminished to 50% ( $p<0.05$ ) when compared with a normal glucose concentration of 5.5 mM. High glucose decreased HUVEC proliferation to 85% ( $p<0.05$ ) compared to normal glucose. Presence of 100 ng/ml VEGF in culture media elevated HUVEC viability at 5.5 mM glucose, but had no effect on high glucose induced reduction in HUVEC viability. Despite addition of VEGF, 25 mM glucose still reduced HUVEC proliferation to 85% compared to 5.5 mM glucose and VEGF ( $p<0.05$ ). Reduction of HUVEC viability and proliferation were in line with a decrease in NO production induced by elevated glucose both in the presence or absence of VEGF. Exposure HUVEC to 50  $\mu\text{M}$  RX871024 at 25 mM glucose in the presence or absence of VEGF drastically decreased endothelial cell viability, to a level of about 10% of that at 25 mM glucose without the imidazoline ( $p<0.005$ ). In contrast, 50  $\mu\text{M}$  efaroxan had no effect on endothelial cell viability in the absence of VEGF, however, decreasing HUVEC viability in the presence of VEGF to 60% ( $p<0.005$ ). Both in the absence and in the presence of VEGF RX871024 reduced HUVEC proliferation to a level of about 50% of that at 25 mM glucose without the imidazoline ( $p<0.005$ ). In comparison efaroxan did not influence HUVEC proliferation regardless the presence of VEGF. Neither of the imidazoline compounds affected significantly HUVEC NO production at elevated glucose concentration regardless the presence of VEGF. Exposure of endothelial cells to 2  $\mu\text{M}$  glibenclamide or 2  $\mu\text{M}$  repaglinide at elevated glucose concentration in the absence of VEGF reduced HUVEC viability to a level of about 70% of that at 25 mM glucose ( $p<0.05$ ). Addition of VEGF abrogated the ability of glibenclamide and repaglinide to diminish HUVEC viability at high glucose concentration. Neither glibenclamide nor repaglinide affected HUVEC NO production in the absence of VEGF. Repaglinide, but not glibenclamide, in the presence of VEGF elevated HUVEC NO production by 80% ( $p<0.05$ ). Neither glibenclamide nor repaglinide affected HUVEC proliferation regardless the presence of VEGF.

**Conclusion:** Our data demonstrate an important interplay between the insulinotropic compounds, the VEGF and the ambient glucose concentration affecting the survival of the vascular endothelial cells. Consequently, this interplay needs to be taken into consideration when designing novel oral insulinotropic compounds for the treatment of diabetes.

## 1254

### Glucagon like peptide-1 protect diabetic cardiomyopathy by inactive endoplasmic reticulum stress pathway

J. Liu, Y. Liu, L. Chen, Y. Wang, X. Song;

The Second Hospital of Jilin University, Changchun, China.

**Background and aims:** Diabetic cardiomyopathy is a heart muscle specific disease which is attributed to abnormal cellular metabolism. This study is aimed to investigate whether endoplasmic reticulum stress (ER stress) is involved in the pathogenesis of diabetic cardiomyopathy and glucagon like peptide-1 (GLP-1) analog liraglutide can protect diabetic cardiomyopathy by inhibiting this pathway.

**Materials and methods:** Type 2 diabetic cardiomyopathy rat models were established by high fat diet for eight weeks and STZ injection 30mg/kg twice. The models are verified by glucose test, echocardiography exam and HE staining for heart tissue. The rats were divided into six groups: non-diabetic cardiomyopathy (CON) group, diabetic cardiomyopathy rats without GLP-1 (DC) treatment, diabetic cardiomyopathy rats with high, medium and low-dose GLP-1 (LIRA-H, LIRA-M, LIRA-L) respectively treatment, and diabetic cardiomyopathy rats with insulin (INS) treatment. The levels of blood glucose, body weight and cardiac function by echocardiography exam were recorded both at baseline and treatment for four weeks and eight weeks. The hemi-quantitative reverse transcription PCR (RT-PCR) were performed to analyze mRNA levels of ATF6, TRAF2 and XBP1, which were considered as the hallmarks genes of ER stress. The expression of ER stress associated proteins including glucose-regulated protein 78 (Grp78), enhancer-binding protein homologous protein (CHOP) and Caspase-12 were also detected by Western blot.

**Results:** The glucose levels are decreased in LIRA or INS group and Liraglutide can improve the cardiac functions which can not been found in INS group ( $p<0.05$ ). The expressions of ATF4, TRAF2 and XBP1 are significantly increased in DC group compared with CON group ( $p<0.05$ ). And GLP-1 treatment can decrease the expression of these genes. The levels of Grp78, CHOP and Caspase-12 also up-regulated in DC group but liraglutide can inactive the expressions of these ER stress related genes ( $p<0.05$ ).

**Conclusion:** Liraglutide can protect diabetic cardiomyopathy by inactive ER stress pathway. The improvement of cardiac function by liraglutide are independent of glucose control.

#### Glyoxalase-I overexpression partially prevents diabetes-induced impaired arteriogenesis in rats

O. Brouwers<sup>1</sup>, L. Yu<sup>1</sup>, P. Niessen<sup>1</sup>, J. Slenter<sup>1</sup>, A. Wagenaar<sup>1</sup>, T. Miyata<sup>2</sup>, M. Post<sup>1</sup>, W. Backes<sup>1</sup>, C. Stehouwer<sup>1</sup>, M. Huijberts<sup>1</sup>, C. Schalkwijk<sup>1</sup>;

<sup>1</sup>Maastricht University Medical Centre, Netherlands, <sup>2</sup>Tohoku University, Sendai, Japan.

**Background and aims:** Arteriogenesis is an important mechanism in improving the outcome of ischemic vascular diseases. However in patients who suffer from diabetes, this adaptive collateral capacity is impaired. Hyperglycemia is the initial factor of diabetes induced vascular damage, but the mechanisms involved are poorly understood. The advanced glycation endproduct (AGE) precursor methylglyoxal (MGO) is a highly reactive oxo-aldehyde, which can be detoxified by the enzyme glyoxalase-I. We hypothesized that diabetes causes dysregulation of the GLO-I enzyme, and that this dysregulation is required for reduced collateral artery remodeling capacity. Therefore we used a GLO-I overexpressing transgenic diabetic rat model with a unilateral femoral artery ligation, to investigate the role of MGO in diabetes-induced impaired arteriogenesis.

**Materials and methods:** Wild-type and GLO-I transgenic rats which were non-diabetic or diabetic (65mg/kg streptozotocin) for a period of 12 weeks were subjected to ligation of the right femoral artery. Blood flow recovery after ligation of the femoral artery was measured by laser Doppler perfusion imaging (LDPI) immediately, 3 and 6 days after ligation. Formation of collateral arteries was measured by in vivo time-of-flight magnetic resonance angiography (MRA) at 7-Tesla before euthanization on day 7.

**Results:** Diabetes resulted in significantly ( $p<0.05$ ) decreased GLO-I protein and activity levels in hind limb skeletal muscle ( $5.1\pm0.3$  U/mg) compared with wild type control rats ( $6.2\pm0.4$  U/mg). GLO-I activity in the skeletal muscle of the transgenic control ( $62.2\pm1.7$  U/mg) and transgenic diabetic group ( $63.3\pm4.2$  U/mg) was approximately 10 times higher than in the wild-type animals. LDPI analyses showed a significantly ( $p<0.05$ ) decreased blood perfusion recovery after 6 days in the diabetic animals ( $45.7\pm0.7$  %) compared with control animals ( $64.5\pm1.0$ ), without any beneficial effect of GLO-I overexpression in the diabetic animals ( $46.7\pm0.9$ %) nor in the control GLO-I animals ( $64.1\pm2.8$  %). MRA analyses showed a significant ( $p<0.05$ ) decrease in the number of collaterals in the wild type diabetic animals (median 1.0, range 0-3) compared with the control animals (median 6.0, range 4-9). GLO-I overexpression partially prevented this decrease in collateral numbers (median 3.0, range 1-5),  $p<0.05$  in the diabetic animals. However GLO-I overexpression did not have any effect in the non-diabetic state (median 5.5, range 3-9).

**Conclusion:** Defective GLO-I might contribute to diabetic impairment of arteriogenic adaptation to ischemia, since the impairment can be rescued by overexpressing the enzyme. In diabetic models with presumed microvasculopathy, laser Doppler imaging may not be suitable to measure the functional improvement by arteriogenesis.

### 1256

#### The tissue damage in cardiac ischaemia-reperfusion injury is reduced under the fed state cellular energy metabolism

M. Dambrova<sup>1,2</sup>, J. Kuka<sup>1</sup>, M. Makrecka<sup>1,2</sup>, E. Liepinsh<sup>1</sup>;

<sup>1</sup>Latvian Institute of Organic Synthesis, <sup>2</sup>Riga Stradins University, Riga, Latvia.

**Background and aims:** It has been hypothesized that better survival of ischemic myocardium cells can be achieved by stimulating glucose oxidation, either directly or secondarily, to partially inhibited FA oxidation. Healthy subjects, depending on the availability of glucose or fatty acids (FA), are able to switch appropriately between the available energy substrates. At a postprandial state, the glucose and insulin concentrations are increased, and glucose oxidation is facilitated. In contrast, in a fasted state, the glucose concentration is significantly lower, and energy metabolism is switched to FA. The aim of the present study was to evaluate the ischemic damage in the heart tissues under fed and fasted states in healthy and diabetic animals with respect to the balance in glucose and fatty acid metabolism.

**Materials and methods:** In fed and fasted Wistar and diabetic Goto-Kakizaki (GK) rats, the blood plasma biochemical parameters were measured. The myocardial infarction experiment in isolated hearts from fed and fasted rats was performed according to the Langendorff technique. The infarct size was calculated as percentage of necrotic tissue in the risk area. In addition, the rate of glucose and FA oxidation and the expression of genes related to energy metabolism were assessed in isolated hearts from fed and fasted rats. All data are expressed as the mean  $\pm$  S.E.M. For statistical analyses, the one-way ANOVA followed by Newman-Keuls Multiple Comparison Test or Student's *t*-test were used.

**Results:** Under the fed state the Wistar rat heart tissues oxidized about 10-fold more glucose and 3-fold less palmitate than under the fasted state ( $p<0.05$ ). The shift in favoured energy substrate was reflected by changes in the insulin and PPAR- $\alpha$ /PGC-1 signalling pathway-regulated expression of genes related to glucose and FA metabolism, respectively. In isolated Wistar rat heart infarction experiment the shift towards glucose metabolism was accompanied by the statistically significant 2.7-fold reduction in the infarct size under fed state ( $27\pm6$ %) as compared to fasted state ( $73\pm5$ %). In GK rats, the infarct size was also reduced in fed ( $46\pm12$ %) in comparison to fasted ( $89\pm4$ %) rat hearts ( $p<0.05$ ). However, the overall infarct sizes in GK rat hearts were increased as compared to Wistar rat hearts which might be related to the insulin resistance-limited oxidation of glucose in GK rat tissues.

**Conclusion:** Our results demonstrate that the cardiac recovery from ischemia-reperfusion injury is more efficient under the fed state due to the facilitated glucose metabolism. Meanwhile, the ischemic injury is more severe under the fasted state due to the prevailing FA metabolism. The switch from FA to glucose oxidation is critical for the survival of cardiac tissues after ischemia-reperfusion reperfusion and long-term fasting might provoke more severe cardiac events in diabetic patients.

### 1257

#### Differences in the development of atherosclerosis between two lines of selectively bred mice with different susceptibilities to diet-induced glucose intolerance

A. Asai, M. Nagao, M. Kawahara, Y. Sato, Y. Nakajima, H. Sugihara, S. Oikawa;

Endocrinology and Metabolism, Nippon Medical School, Tokyo, Japan.

**Background and aims:** Epidemiological studies indicate that postprandial hyperglycaemia is an independent risk factor for atherosclerotic cardiovascular disease. However, there have been few suitable animal models for understanding the involvement of blood glucose fluctuations in the pathogenesis of atherosclerosis in vivo. We recently established two lines of mice with different susceptibilities (prone and resistant) to high fat diet (HFD)-induced glucose intolerance by selective breeding (designated SDG-P and SDG-R, respectively). After receiving HFD (32% energy as fat) for 5 weeks, SDG-P mice show evident glucose intolerance in OGTT relative to SDG-R. In this study, we assessed differences in the development of atherosclerosis in the newly established two lines of mice with different glucose intolerance.

**Materials and methods:** Female mice of each strain (SDG-P and SDG-R) fed an atherogenic diet (AD; 1.25% w/w cholesterol, 36% energy as fat) for 20 weeks (8-28 weeks of age). OGTT (2.0 g/kg body weight) was performed before and after the AD feeding. For quantitative analysis of atherosclerotic lesion formation, serial frozen sections (10  $\mu$ m thickness, spanned 450  $\mu$ m) of aortic sinus were prepared after the 20-week AD feeding. The lesion size was calculated from Oil Red O-stained area (mean of 9 sections, each separated by 50  $\mu$ m). Data are expressed as mean $\pm$ SD. Differences between strains were assessed using Student's *t* test. Correlations between lesion area and blood measurements were examined by Pearson's correlation analysis.

**Results:** In OGTT, SDG-P mice showed modest glucose intolerance as compared with SDG-R mice even before AD feeding (SDG-P vs SDG-R: AUC<sub>0-120 min</sub>;  $1424\pm289$  vs  $1148\pm170$  mmol/l $\cdot$ min,  $n=8-9$ ,  $p=0.035$ ). The differences in glucose tolerance between the two strains became more evident after receiving AD for 20 weeks (AUC<sub>0-120 min</sub>;  $1605\pm446$  vs  $738\pm113$  mmol/l $\cdot$ min,  $n=9$ ,  $p<0.0001$ ). After AD feeding, mean aortic sinus lesion area in SDG-P mice was approximately 3-fold greater than that in SDG-R mice ( $12.9\pm7.6$  vs  $4.2\pm3.4 \times 10^3 \mu\text{m}^2$ ,  $n=12-14$ ,  $p=0.0012$ ). No significant differences were observed in plasma cholesterol levels (total, HDL, nor non-HDL) between the two strains, whereas SDG-P mice showed higher plasma triacylglycerol concentration than SDG-R mice ( $p=0.0052$ ). Aortic sinus lesion area was strongly correlated with blood glucose levels in OGTT (AUC<sub>0-120 min</sub>;  $r=0.67$ ,

$p=0.0023$ ), whereas no significant correlations were observed between the lesion area and any of the plasma lipid measurements.

**Conclusion:** These results demonstrate that HFD-induced glucose intolerance-prone mice (SDG-P) are more susceptible to atherosclerotic lesion formation relative to glucose intolerance-resistant mice (SDG-R). The newly established two lines of mice with different glucose intolerance may be useful animal models for investigating the involvement of blood glucose fluctuations in the pathogenesis, prevention, and treatment of atherosclerotic complications.

### Natural products to treat diabetes: effects of acute and chronic administration of aloe vera in a mouse model of type 2 diabetes

Y. Brito-Casillas<sup>1</sup>, J.C. Wiebe<sup>1</sup>, L. López-Ríos<sup>1</sup>, C. Muñoz-Mediavilla<sup>2</sup>, A. Arín-Martínez<sup>1</sup>, J. Nóvoa<sup>1,3</sup>, A.M. Wäagner<sup>1,3</sup>;

<sup>1</sup>Servicio de Endocrinología, Unidad de Investigación del Complejo Universitario Insular Materno Infantil de Gran Canaria, Las Palmas de Gran Canaria, <sup>2</sup>Universidad de Cádiz, <sup>3</sup>Departamento de Ciencias Médicas y Quirúrgicas, Universidad de Las Palmas de Gran Canaria, Spain.

**Background and aims:** Natural products are a potential source of new treatments for diabetes. Aloe vera has shown glucose-lowering effects in human and animal studies, but more accurate evaluations are required. Our aims were to evaluate acute and chronic effects of aloe administration in diabetic C57BL/6 mice.

**Materials and methods:** 16 weeks old C57BL/6 ( $n=10/\text{group}$ , 50% males) were fed a 60%-fat diet for at least 20 weeks. In order to assess its short-term effects, several doses of aloe leaf pulp extract (11–20% acemannan) or saline was administered orally with 2 g glucose/Kg during a glucose tolerance test (OGTT), on different days, in a randomised cross-over design. The most effective dose was fed in the diet for 90 days to diabetic C57BL/6 mice and compared with high-fat diet only ( $n=10/\text{group}$ , 50% males). Body weight (BW), food and water consumption, welfare state and external appearance were assessed weekly.  $\text{HbA}_{1c}$  (DCA, Siemens), OGTT and intra-peritoneal insulin tolerance tests (ITT) were performed before and after treatment. Glucose (Glucocard G+) and insulin (ELISA) concentrations were measured. AUCs were calculated by the trapezoid rule. Cold allodynia response was assessed by the acetone test, where higher scores indicate more severe neuropathy. Blood sampling and macroscopic organ evaluation, were performed post-mortem. For comparisons between groups, Wilcoxon's test or Student's test for paired data were used. A two-tailed  $p<0.05$  was considered significant.

**Results:** Short-term experiments showed a hypoglycaemic effect of aloe, when compared to saline (at 15 min  $240.1 \pm 25.3$  vs  $311.9 \pm 54.9$  mg/dl,  $p=0.003$ ; AUC  $270.8 \pm 34.6$  vs  $307.3 \pm 61.7$ ,  $p=0.016$ ). After chronic treatment, no significant differences were observed between groups overall, regarding OGTT, ITT,  $\text{HbA}_{1c}$  or the rest of blood tests. Response to cold allodynia, however, was improved in the treatment group ( $2.08 \pm 0.51$  vs  $2.63 \pm 0.23$ ,  $p=0.006$ ) at the expense of the female mice. In the treated female mice, final  $\text{HbA}_{1c}$  was lower than in controls ( $4.76 \pm 0.17$  vs  $4.84 \pm 0.35$ ,  $p=0.049$ ), whereas glucose concentrations during the ITT (at 15 min  $100.7 \pm 14$  vs  $75.9 \pm 14$  mg/dl;  $p=0.024$ ) and insulinemia during the OGTT (at 60 min,  $0.41 \pm 0.03$  vs  $0.1 \pm 0.09$  ng/ml,  $p=0.044$ ) were higher. Treated males showed a higher final BW ( $54.9 \pm 2.1$  vs  $50.7 \pm 3.4$ ,  $p=0.045$ ), a relatively higher weight of the pancreas (pancreas/BW) ( $0.56 \pm 0.003$  vs  $0.48 \pm 0.004$  %,  $p=0.012$ ) and a relatively lower left paragenital fat weight ( $0.76 \pm 0.14$  vs  $1.4 \pm 0.17$  %,  $p=0.001$ ). A similar, non-significant trend was found in females. In addition, potential signs of ageing, such as grey hair and alopecia appeared an average of 35 days later in the treatment than in the control group.

**Conclusion:** Orally administered aloe vera acutely reduces blood glucose in diabetic mice. Longer-term treatment increases insulin secretion and improves glucose control in females. Cold allodynia inhibition could be a result of better glucose control, but a direct effect of aloe on pain or on neuropathy itself cannot be ruled out. External appearance, pancreas and fat changes will be further evaluated.

## 1259

### Superoxide anion overproduction, impaired eNOS and enhanced adhesion molecule expression in human endothelial cells exposed to maternal diabetes

S.A.A. Sultan, A.M. Graham;

Medical Sciences, University of Bradford, UK.

**Background and aims:** Epidemiological studies suggest a link between foetal exposure to maternal diabetes and propensity to develop various diseases including cardiovascular disease in adulthood. The present study measured levels of superoxide anion production and determined effects on expression of endothelial nitric oxide synthase (eNOS) and adhesion molecules in HUVEC from diabetic mothers compared to healthy mothers (control) under normoglycemic and hyperglycemic conditions.

**Material and methods:** Intracellular superoxide was measured by both nitrotriazolium blue (NBT) and 2',7'-Dichlorodihydrofluorescein Diacetate (DCFH-DA) experiments. Expression of eNOS mRNA was quantified by real time PCR. The expression of adhesion molecules E-selectin and intracellular adhesion molecule-1 (ICAM-1) were determined by immunofluorescence staining.

**Results:** Both NBT and DCFH-DA experiments showed that diabetic HUVEC cultured in physiologic glucose concentrations for 1–3 days generated excess ROS ( $p<0.05$ ) compared to control cells. However, exposure of diabetic HUVEC to elevated glucose (29mM) had no additional effect. Expression of eNOS mRNA was significantly reduced in diabetic HUVEC compared to control at 5 mM glucose ( $p<0.001$ ). A similar reduction was observed in diabetic HUVEC incubated at 29mM glucose for 10 days when compared to same cells at 5mM glucose ( $p<0.05$ ). We also report for the first time the increased expression of E-selectin ( $p<0.05$ ) and ICAM-1 ( $p<0.05$ ) in unstimulated diabetic HUVEC compared to control.

**Conclusion:** This study showed that exposure of HUVEC to maternal diabetes causes irreversible alterations in endothelial cell gene expression and function in cultured cells even after glucose normalisation and may contribute to increased risk of cardiovascular diseases in adulthood.

## 1260

### Role of p66Shc in the modulation of endothelial leukocyte recruitment

M.R. Orlando, L. Laviola, M. Incalza, A. Leonardini, A. Cignarelli, F. Tortosa, R. Labarbuta, S. Perrini, A. Natalicchio, F. Giorgino; Endocrinology & Metabolic Diseases, University of Bari, Italy.

**Background and aims:** Endothelial cells actively participate in inflammatory events leading to atherogenesis by regulating leukocyte recruitment via the expression of adhesion molecules. The protein p66Shc has been proposed as a sensor/generator of oxidative stress and a mediator of vascular dysfunction. The aim of this work was to investigate the role of p66Shc in cytokine-triggered leukocyte recruitment by human umbilical vein endothelial cells (HUVEC).

**Materials and methods:** Expression and phosphorylation levels of specific signaling molecules were assessed by immunoblotting techniques. Intracellular ROS generation, in the presence of the DHE probe, was evaluated by fluorimetric analysis. Gene expression was evaluated by real-time RT-PCR. Wild-type p66Shc and mutant p66Shc, in which Ser36 was replaced by Ala (p66Shc-Ala36), were selectively overexpressed in HUVEC by infecting cells with recombinant adenoviruses. Selective silencing of p66Shc was obtained with specific siRNAs. Leukocyte transmigration was detected with a commercially available kit.

**Results:** Exposure of HUVEC to 50 ng/ml TNF- $\alpha$  resulted in increased phosphorylation of p66Shc on Ser36 and intracellular ROS levels, and promoted leukocyte transmigration through the HUVEC monolayer ( $p<0.05$ ). TNF- $\alpha$  also induced a marked increase in the expression of the adhesion molecule E-Selectin ( $p<0.05$ ). Adenovirus-mediated overexpression of p66Shc in HUVEC resulted in enhanced p66Shc phosphorylation on Ser36, increased ROS and E-Selectin levels, and marked augmentation of leukocyte transmigration ( $p<0.05$ ), which appeared to be further increased when cells were exposed to TNF- $\alpha$ . Conversely, overexpression of a phosphorylation-defective p66Shc protein, with Ser36 mutated to Ala, did not augment ROS levels or E-Selectin expression beyond those found in wild-type cells, and modestly increased leukocyte transmigration, with an additional effect of TNF- $\alpha$  exposure comparable to that found in control cells. Moreo-

ver, silencing of p66Shc with two independent siRNA sequences resulted in marked reduction of E-Selectin expression, both under basal conditions and following TNF- $\alpha$  exposure ( $p < 0.05$ ), which was associated with decreased leukocyte transmigration ( $p < 0.05$ ).

**Conclusion:** The p66Shc protein acts as a novel intermediate in the TNF- $\alpha$  signaling pathway regulating the adhesive properties of endothelial cells, which involve at least in part changes in E-Selectin expression. The effects of p66Shc in this pathway require cytokine-mediated phosphorylation of the protein on Ser36.

## 1261

### Impaired pancreatic blood flow due to high-fat diet (HFD); pancreatic fluoro-2-deoxy-D-glucose ( $[^{18}\text{F}]\text{FDG}$ ) kinetics and validation

H. Honka<sup>1</sup>, J.C. Hannukainen<sup>2</sup>, M. Tarkia<sup>2</sup>, V. Oikonen<sup>2</sup>, A. Saraste<sup>2</sup>, M. Teräs<sup>2</sup>, J. Knuuti<sup>2</sup>, V. Fagerholm<sup>1</sup>, K. Mikkola<sup>1</sup>, P. Nuutila<sup>2</sup>;

<sup>1</sup>University of Turku, <sup>2</sup>Turku PET Centre, Finland.

**Background and aims:** Mechanisms behind  $\beta$ -cell exhaustion and ensuing hyperglycaemia in obesity include lipotoxicity, endoplasmic reticulum (ER) and oxidative stress, and systemic inflammation. Furthermore, pancreatic microvascular dysfunction and subsequent islet ischaemia has been recently hypothesized to trigger vicious cycle ultimately leading to  $\beta$ -cell insufficiency. Positron emission tomography with computed tomography (PET-CT) is a sophisticated method of studying parameters in organs with compromised accessibility. Aim of the present study was to validate the use of PET for pancreas and to investigate the effects of high-fat diet on pancreatic perfusion and glucose uptake.

**Materials and methods:** Eighteen pigs were randomized into an intervention group and control group. Pigs in the intervention group received first streptozotocin injections and thereafter high-fat diet (HFD) for 6 months. Diet containing either 15 % lard + 1.5 % cholesterol ( $n = 6$ ) or 20 % lard + 4 % cholesterol ( $n = 4$ ). The control group received regular farm nutrition. Fasting state PET-CT scans with sequential radiowater ( $[^{15}\text{O}]\text{H}_2\text{O}$ ) and  $[^{18}\text{F}]\text{FDG}$  boluses were performed and blood was sampled to measure plasma biochemical and metabolic parameters. After the scanning, sacrifice and laparotomy was done, and pancreas was explanted to measure autoradiographic accumulation of  $^{18}\text{F}$ , and *ex vivo* tissue radioactivity. Pancreatic volumes-of-interest (VOIs) were drawn to head, corpus, and tail of the pancreas. Glucose uptake was measured from *ex vivo* tissue samples, and with fractional uptake rate (FUR) and Gjedde-Patlak plot. Blood flow was calculated using one-tissue compartmental model.

**Results:** High fat diet was associated with weight gain ( $127 \pm 7.6$  vs.  $83 \pm 9.2$  kg,  $p < 0.001$ ), hypercholesterolaemia ( $12 \pm 3.5$  vs.  $2.1 \pm 0.3$  mmol/l,  $p < 0.001$ ), and hyperglycaemia ( $12 \pm 2.2$  vs.  $6.0 \pm 2.2$  mmol/l;  $p < 0.01$ ). Blood flow in the pancreas was lower in the intervention group ( $35 \pm 16$  vs.  $57 \pm 26$  ml/100g $\cdot$ min;  $p < 0.05$ ), but baseline glucose uptake rates were similar between groups ( $0.082 \pm 0.054$  vs.  $0.063 \pm 0.027$   $\mu\text{mol}/\text{ml}\cdot\text{min}$ , NS). PET derived  $[^{18}\text{F}]\text{FDG}$  influx values were correlated with values measured from *ex vivo* tissue samples ( $r = 0.63$ ,  $p < 0.01$ , and  $r = 0.87$ ,  $p < 0.01$  for FUR and Gjedde-Patlak to *ex vivo*, respectively). Pancreatic glucose uptake was homogeneous in both groups with no identifiable islets.

**Conclusion:** The results of our study indicate that PET-CT is feasible for the assessment of pancreatic metabolism and perfusion. Secondly, perfusion is blunted after long lasting HFD intervention. Since islets are normally highly perfused and consume nearly 20 % of pancreatic total blood flow, this dysfunction might cause subtle islet ischaemia and  $\beta$ -cell insufficiency in time.

### In vitro determination of the hepatotoxic effects of methylglyoxal

T. Loganathan<sup>1</sup>, T. Buxton<sup>1</sup>, J. Mabley<sup>2</sup>;

<sup>1</sup>Brighton and Sussex Medical School, <sup>2</sup>School of Pharmacy & Biomolecular Sciences, University of Brighton, UK.

**Background and aims:** Methylglyoxal (MGO), a glycolysis derived reactive dicarbonyl compound has been implicated as a central mediator of diabetic complications. Recently diabetes has been found to be an independent risk factor for development of liver disease including non-alcoholic fatty liver disease (NAFLD). Hepatocyte exposure to saturated fatty acids results in loss of cell viability, increase in apoptosis and increased inflammation as dem-

onstrated by IL-8 release leading to NFLD, as diabetes increases the risk of developing this disease we hypothesize that MGO may have similar effects on hepatocytes as fatty acids. The aim of this study therefore was to determine the effects of MGO on hepatocytes.

**Materials and methods:** The human hepatocyte cell line, HepG2, was exposed to MGO (0.1–1 mM) for 24 h. Cell viability was determined using the MTT assay and cell death assessed by propidium iodide/Hoechst staining. Oxidative stress was measured using the nitroblue tetrazolium assay. Inflammation was assessed by IL-8 release measured using a commercially available ELISA kit. HepG2 cells were also exposed to MGO (0.6–1 mM)  $\pm$  aminoguanidine (0.1–0.5 mM) and again cell viability, death, oxidative stress and IL-8 was measured.

**Results:** Hepatocytes exposed to MGO for 24 h showed a dose-dependent decrease in cell viability with 0.6 mM and 0.8 mM reducing it to  $68 \pm 2\%$  and  $54 \pm 3\%$  respectively ( $p < 0.05$  vs. untreated cells). There was also an increase in both necrosis, from  $7 \pm 2\%$  to  $42 \pm 2\%$  and  $48 \pm 1\%$ , and apoptosis, from  $0.5 \pm 0.3\%$  to  $3.4 \pm 1$  and  $2.8 \pm 0.5\%$ , for 0.6 mM and 0.8 mM MGO respectively ( $p < 0.05$  vs. untreated cells). Both 0.6 mM and 0.8 mM MGO also increased oxidative stress following a 6 h exposure by  $40 \pm 2\%$  and  $60 \pm 5\%$  respectively ( $p < 0.05$  vs. untreated cells). IL-8 release was increased by MGO concentrations as low as 0.3 mM with a  $20 \pm 7\%$ ,  $29 \pm 1\%$  and  $38 \pm 2\%$  increase observed with 0.3, 0.6 and 0.8 mM respectively ( $p < 0.05$  vs. untreated cells). All these effects were reversed by simultaneous addition of aminoguanidine (0.5 mM) with cell viability being returned to  $86 \pm 2\%$  and  $77 \pm 3\%$  for 0.6 and 0.8 mM MGO ( $p < 0.05$  vs. MGO alone) and similar protective effects observed on cellular oxidative stress, necrosis and apoptosis levels and IL-8 release.

**Conclusion:** Physiological concentrations of MGO reduced hepatocyte cell viability and increased levels of both necrosis and apoptosis. In addition inflammation as assessed by hepatocyte release of IL-8 was also increased by MGO. These effects may be mediated by the increased cellular oxidative stress observed in hepatocytes following MGO exposure. Aminoguanidine, a scavenger of MGO, protected hepatocytes from the MGO-mediated damaging effects. In conclusion, MGO has similar effects on hepatocytes as fatty acids suggesting a possible synergistic effect between fatty acids and MGO that may explain why diabetics have an increased risk of developing liver diseases such as NAFLD.

## 1263

### Intramuscular allogeneic mesenchymal stem cells are of comparable efficacy to syngeneic MSCs in hind limb ischaemia of diabetic animals

A. Liew<sup>1</sup>, C. Baustian<sup>1</sup>, D. Thomas<sup>1</sup>, E. Vaughan<sup>1</sup>, X. Chen<sup>1</sup>, C. Sanz Nogues<sup>1</sup>, M. Creane<sup>1</sup>, S. Alagesan<sup>1</sup>, P. Owens<sup>2</sup>, J. Horan<sup>1</sup>, R. Ceredig<sup>1</sup>, P. Dockery<sup>3</sup>, M. Griffin<sup>1</sup>, A. Duffy<sup>4</sup>, T. O'Brien<sup>1</sup>;

<sup>1</sup>Regenerative Medicine Institute, <sup>2</sup>Centre for Microscopy and Imaging and NBIPI, <sup>3</sup>Department of Anatomy, <sup>4</sup>Medtronic, Galway, Ireland.

**Background and aims:** Peripheral arterial disease (PAD) is prevalent and is associated with an increased risk of death and ischemic events. PAD is associated with a worse outcome in the presence of diabetes mellitus. Mesenchymal stem cells (MSCs) have been demonstrated to enhance therapeutic neovascularisation. Allogeneic MSCs have an advantage in that they may be used as 'off the shelf' product as they can be prepared in advance and they can be isolated from non-diabetic donors thus avoiding the problem related to sufficient cell number and disease-induced cellular dysfunction. The direct comparison of the efficacy of transplantation of allogeneic and syngeneic MSC transplantation from diabetic and non-diabetic donors respectively into a diabetic animal model is currently unknown.

**Materials and methods:** Syngeneic and allogeneic MSCs were isolated from diabetic obese dbdb/C57BKS(H-2d) and non-diabetic C57BL/6(H-2b) mice respectively. Angiogenesis array was performed on the MSC conditioned media. Normal saline, allogeneic or syngeneic MSCs ( $1 \times 10^6$ ) were administered intramuscularly into the ischaemic thigh of diabetic obese dbdb/C57BKS(H-2d) following the induction of unilateral hindlimb ischaemia (HLI). Blood perfusion and clinical assessment of the ischaemic limbs were determined twenty one days following the induction of HLI.

**Results:** MSCs derived from both sources secrete various angiogenesis related factors. Some of these factors were found at a lower amount or absent in the conditioned media of the dbdb/C57BKD(H-2d) group as compared to the C57BL/6(H-2b) group. Syngeneic MSCs significantly improved blood perfusion as compared to the control group only at week two. However, allogeneic MSCs significantly improve blood perfusion as compared to the control group at all time points studied after transplantation. The improvement of blood perfusion in both the allogeneic and syngeneic MSC groups was not

statistically different. The percentage of toe necrosis were 86%(6/7), 86%(6/7) and 50%(4/8) in the control, syngeneic and allogeneic groups respectively. Toe amputation was only seen in the control group (14%) but not in the other groups.

**Conclusion:** Both autologous or allogeneic MSC transplantation have similar efficacy in the diabetic hindlimb ischaemic setting.

## PS 112 Diabetes and sleep apnoea

### 1264

#### Prevalence of obstructive sleep apnoea in type 2 diabetes patients

L. Tarnow<sup>1</sup>, H. Storgaard<sup>2</sup>, T.P. Almdal<sup>2</sup>, M. Laub<sup>3</sup>;

<sup>1</sup>Clinical Research Unit, Steno Diabetes Center, <sup>2</sup>Steno Diabetes Center, Gentofte, <sup>3</sup>Respiratory Centre East, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Obstructive Sleep Apnoea (OSA) is associated with increased cardiovascular mortality and morbidity. We, therefore, aimed to investigate the prevalence of OSA among type 2 diabetes (T2DM) patients referred to a tertiary referral centre.

**Materials and methods:** All patients referred to the T2DM clinic during 10 months were offered to participate in a three-stage screening program for the diagnosis of OSA; 1. The Berlin questionnaire. A “high likelihood of OSA”-score qualified for; 2. an outpatient ApneaLink® monitoring. Patients with a positive test (apnea-hypopnea index (AHI) > 5/hour) were referred to; 3. diagnostic polygraphy (with Embletta®) in a sleep clinic.

**Results:** A total of 180 patients (men, 61%; age  $59.7 \pm 10.5$  years, BMI,  $31.8 \pm 6.7$  kg/m<sup>2</sup>, diabetes duration  $8.2 \pm 6.3$  years, HbA1c,  $7.3 \pm 1.2\%$ ) participated. Amongst these 104 (61%) had a “high likelihood of OSA”-score according to the Berlin questionnaire, and 77 patients (43%) were after ApneaLink® study referred to the sleep clinic. So far, polygraphy has been performed in 49 patients, and 44 have been diagnosed with OSA - corresponding to an estimated prevalence of OSA of 34 % of the entire study population (n=180). ApneaLink® positive (n = 77) patients had higher BMI ( $34.3 \pm 7.4$  versus  $30.3 \pm 5.7$  kg/m<sup>2</sup>,  $p < 0.001$ ), higher HbA1c ( $7.6 \pm 1.3$  versus  $7.2 \pm 1.1\%$ ,  $p = 0.008$ ) and lower HDL-cholesterol ( $1.1 \pm 0.3$  versus  $1.3 \pm 0.4$  mmol / l,  $p = 0.003$ ) as compared with those without symptoms (n = 77) or signs of OSA on ApneaLink® (n = 26). The groups were comparable with respect to: blood pressure, albuminuria, p-creatinine, retinopathy, LDL cholesterol, treatment with oral antidiabetic drugs, RAS blockade and statins. In a multiple linear regression analysis, AHI increased significantly with higher age, increased BMI and declining HDL-cholesterol, whereas sex, HbA1c and insulin dose per kg bodyweight were not related to AHI.

**Conclusion:** Every third T2DM patient referred for treatment in a hospital outpatient clinic have OSA. Increased focus on screening, diagnosis and treatment of OSA in T2DM patients is needed.

### 1265

#### Prevalence and clinical characteristics of insulin dependent patients suffering from sleep apnoea syndrome

A. Iosup, J. Courrèges, H. Banciu, J. Thuan, N. Vigier Simorre, H. Bonneure; Centre Hospitalier Général de Narbonne, France.

**Background and aims:** If the frequency of the sleep apnea syndrome (SAS) is noticeable in the general population and a major issue for type 2 diabetic patients (T2D), its prevalence and characteristics have not really been studied in type 1 diabetic patients. Thus the following research aims at determining SAS' prevalence and its characteristics in type 1 diabetic (T1D) patients.

**Materials and methods:** 81 T1D patients over 18 years old (average age  $53.4 \pm 14.6$  years, sex ratio M/F 1.04, diagnosed with diabetes for  $23.3 \pm 12.9$  years) were enrolled in chronological order. They benefited from a systematic SAS screening on a clinical level (Epsworth scale + simplified Berlin scale) and a respiratory level (pulse oxymetry). In case of abnormality and/or doubt, we performed a polysomnography (EPS, n=36) in order to confirm SAS diagnosis. Patients diagnosed with SAS were classified into 2 groups: severe SAS or moderate SAS. Severe SAS was defined by apnea hypopnea index (AHI)  $\geq 30$ /h and moderate SAS by AHI [10;30] with a number of micro awakenings  $\geq 10$ /h.

**Results:** 22 (27.1%) of T1D patients were diagnosed with obstructive SAS (average AHI:  $26.8 \pm 11.8$  /h), among which 12 (14.8%) were classified as severe SAS (average AHI:  $37.3 \pm 7.7$  /h) and 10 (12.3%) as moderate SAS (average AHI:  $18 \pm 5.8$  /h + average number of micro awakenings:  $142 \pm 103$ /night). We compared clinical and oxymetry characteristics of patients suffering from SAS (n=22) with those of patients with no SAS (n=59). At least 2 out of 4 clinical signs were significantly noticed (90 vs 50% -  $p < 0.001$ ) in SAS patients (snoring: 65 vs 27%, discontinuous sleep: 50 vs 23%, morning asthenia : 55 vs 19 % and day somnolency : 55 vs 19 %), as well as oxymetry results (SAS vs no SAS): desaturation index  $10.6$  vs  $1.6$  -  $p < 0.0001$  and lowest SpO<sub>2</sub>: 76 vs 84 % -  $p < 0.004$ . There were no differences (SAS vs no SAS) in diabetes

duration (24.9 vs 22 years), HbA1c (7.8 vs 8.1%), blood pressure (124/76 vs 126/72 mmHg), BMI (25.4 vs 24.5 kg/m<sup>2</sup>) and lipid status. There were differences (SAS vs no SAS) in age ( $62 \pm 13$  vs  $49 \pm 14$  years -  $p < 0.01$ ), percentage of males (72.7 vs 45.8 % -  $p < 0.03$ ), macroangiopathy frequency (76.2 vs 35.2 % -  $p < 0.001$ ) and microangiopathy frequency (95.5 vs 61.5 % -  $p < 0.003$ ), and particularly autonomic neuropathy (and not peripheral neuropathy) with 71.4 vs 21 % -  $p < 0.004$  (mostly unfelt hypoglycemia 63.6 vs 22.6 % -  $p < 0.0007$ ).

**Conclusion:** SAS frequency although poorly explored in T1D patients, is significantly noticeable (27%). The clinical profile of T1D SAS patients is very different from the one of general population or of T2D patients. This study identifies in elderly, normal weighted patients, an increase in macro and microangiopathy (especially autonomic neuropathy) frequency, therefore creating new physio pathological research axes.

## 1266

### A new device for screening severe form of obstructive sleep apnoea in patients with type 2 diabetes

J.-P. Le Berre<sup>1</sup>, G. Chaumet<sup>2</sup>, A. Courson<sup>1</sup>, H. Moussa Ali<sup>3</sup>, B. Colle<sup>1</sup>, C. Mounier<sup>1</sup>, O. Coste<sup>1</sup>;

<sup>1</sup>Department of endocrinology, Hospital Desgenettes, Lyon, France, <sup>2</sup>UMR MD2, University of Marseille, France, <sup>3</sup>Military Health Service of Djibouti, Republic of Djibouti.

**Background and aims:** Obstructive sleep apnoea syndrome (OSAS) is a highly prevalent comorbidity of type 2 diabetes. Patients with type 2 diabetes have high risk of cardiovascular disease and OSAS is often misestimated. The aim of this study was to evaluate the ability of an automatic respiratory events recorder, i.e. the RU SLEEPING (PHILIPS-RESPIRONICS inc), in severe OSAS detection. In this study, the results obtained with this device were systematically compared with the index determined by polysomnography in patients with type 2 diabetes.

**Materials and methods:** We performed a prospective study, including 64 patients with type 2 diabetes. Two nights sleep recordings staggered-in-time were realised for each patient: the first one with RU SLEEPING system and the second one with polysomnography (PSG). Two criteria were obtained from RU SLEEPING system: the mean Respiratory Event Index (REI) and the maximum Respiratory Event value (max-REV) observed per hour of recording. Then, both criteria were compared to the gold standard, i.e. the Apnea-Hypopnea Index (AHI) determined by PSG using a linear correlation method. The performances of the RU SLEEPING in the detection of OSAS (AHI > 10) and severe form of OSAS (AHI > 30) were then studied using ROC curves and best kappa method for the determination of cut-off values. Contingency tables were built and sensitivity (Se), specificity (Sp) and positive and negative predictive values (PPV and NPV) were finally calculated from these tables.

**Results:** According to method of linear regression, m-REI and max/h REI were correlated with AHI ( $r = 0.71$  and  $r = 0.69$ ). Area under curve (AUC) of ROC curve was to 0.84 (when AHI > 10) and to 0.86 (when AHI > 30) for REI. AUC was to 0.87 (when IHA  $\geq 10$  and  $\geq 30$ ) for max-REV. According to the best kappa method, the values of cut-off were respectively: for IAH > 10, REI = 3 RE/h (Se = 97 %, Sp = 33%, PPV = 93%, NPV = 50%) and max-REV = 15 RE (Se = 93 %, Sp = 50%, PPV = 95%, NPV = 43%) and for IAH > 30, REI = 12 RE/h (Se = 78 %, Sp = 84%, PPV = 83%, NPV = 79%) and max-REV = 43 RE (Se = 81 %, Sp = 78%, PPV = 79%, NPV = 81%).

**Conclusion:** These results showed that RU SLEEPING system may constitute a valuable device for screening severe forms of obstructive sleep apnea syndrome in patients with type 2 diabetes, compared to polysomnography. The values of best cut-off were 12 respiratory events per hour for REI and 43 respiratory events for max-REV.

### Blood glucose improvement ameliorates nocturnal arterial oxygen saturation in type 2 diabetic patients: a case-control study

A. Lecube<sup>1</sup>, A. Ciudin<sup>1</sup>, G. Sampol<sup>2</sup>, S. Valladares<sup>1</sup>, J. Mesa<sup>1</sup>, C. Hernández<sup>1</sup>, R. Simó<sup>1</sup>;

<sup>1</sup>Endocrinology Department, Diabetes and Metabolism Research Unit., CIBER de Diabetes y Enfermedades Metabólicas Asociadas, Instituto de Salud Carlos III, Institut de Recerca i Hospital Universitari Vall d'Hebron,

<sup>2</sup>Sleep Unit, Pneumology Department., CIBER Enfermedades Respiratorias. Instituto de Salud Carlos III, Institut de Recerca i Hospital Universitari Vall d'Hebron, Barcelona, Spain.

**Background and aims:** There is growing evidence suggesting a deleterious effect of type 2 diabetes on lung function and sleep breathing, and diabetes has been described as an independent risk factor for severe nocturnal hypoxemia. Our aim was to determine the effect of blood glucose control improvement on nocturnal arterial oxygen saturation.

**Materials and methods:** A case-control study including 30 type 2 diabetic patients and 10 non-diabetic subjects, closely matched by age, gender, and BMI, was conducted. The nocturnal oxygen desaturation index (ODI) was calculated at baseline and 5-day after blood glucose control had improved. Four different oxygen desaturation thresholds (reductions in SaO<sub>2</sub>  $\geq 3\%$ ,  $4\%$ ,  $6\%$ , and  $8\%$ ) as indicators of hypoxemia severity (ODI-3%, ODI-4%, ODI-6%, and ODI-8%) were used.

**Results:** At baseline, diabetic patients showed a significantly higher percentage of ODI-3%, ODI-4%, and ODI-6% in comparison with non-diabetic subjects. Fasting plasma glucose and HbA1c positively correlated with the cumulative percentage of time spent with oxygen saturation below 90% (CT90). In addition, multiple linear regression analyses showed that HbA1c was independently associated with ODI-3%, ODI-4%, and ODI-6%. A significant reduction in ODI-3% ( $39.8 \pm 27.5$  vs.  $32.5 \pm 27.5$  events/hour,  $p < 0.001$ ), ODI-4% ( $28.5 \pm 23.7$  vs.  $23.5 \pm 24.2$ ,  $p < 0.001$ ), and ODI-6% ( $15.1 \pm 16.8$  vs.  $12.9 \pm 17.3$ ,  $p = 0.009$ ) was observed after 5 days of blood glucose optimization. By contrast, no changes in ODI events were observed in non-diabetic patients after 5-days of follow-up. Finally, no significant changes in weight were observed in both groups.

**Conclusion:** Our baseline results confirm and extend previous reports concerning the impairment of nocturnal oxymetry that occurs in diabetic patients. Glycemic control improvement reduces the increase of nocturnal ODI that exists in T2DM. The reason why the improvement of glycemic control results in less nocturnal hypoxia remains to be elucidated. However, the rapid effect without changes in body weight suggests a central mechanism on respiratory center output.

**Figure.** Changes in oxygen desaturation index per hour (ODI) at baseline (black bars) and at discharge (white bars) in type 2 diabetic patients (after 5-days of glucose improvement) and control subjects.

\*:  $p < 0.05$  between baseline and discharge.

## 1268

## High prevalence of GAD65 antibodies in type 2 diabetes mellitus females with sleep apnoea syndrome

P.B. Katchunga<sup>1</sup>, Y. Mahadeb<sup>2</sup>, S.A. Ahn<sup>3</sup>, M.F. Rousseau<sup>3</sup>, M.P. Hermans<sup>2</sup>, J.C. Cikomola<sup>1</sup>;<sup>1</sup>Université Catholique de Bukavu, Democratic Republic of the Congo,<sup>2</sup>Endocrinology & Nutrition, <sup>3</sup>Cardiology, Université Catholique de Louvain, Brussels, Belgium.

**Background and aims:** Obstructive sleep apnoea syndrome (OSAS) is a frequently overlooked comorbidity in type 2 diabetes (T2DM). OSAS is associated with obesity, metabolic syndrome (MetS), and central fat accretion. OSAS is more frequent in males, who as a result, more often benefit from screening. The study aimed at documenting the barely-assessed sexual dimorphism of OSAS in T2DM beyond common gender differences.

**Materials and methods:** cross-sectional study of 815 adults with T2DM (541 males; 274 females) classified into OSAS[−] and OSAS[+] according to polysomnography's apnoea-hypopnea index, and assessed for cardiometabolic risk factors, glucose homeostasis (HOMA B and S), micro/macrovacular complications, UKPDS 10-year CV risk, thyroid function and autoimmunity (TSH; antiTG, antiTPO; prevalence of autoimmune thyroid disease (AITD); and GAD65 autoantibodies).

**Results:** Overall OSAS prevalence was 16% in the entire group: 18% in males and 11% in females (p 0.0032). There was no significant OSAS-related gender dimorphism for age; education; and diabetes duration. There was a significant dimorphism in ethno-geographical extraction (higher proportion of Maghrebian females with OSAS). There were no sexual-specific dimorphisms related to OSAS in body composition and overall anthropometrics, nor in hypertension prevalence, MetS, HOMA insulin sensitivity [S], HOMA hyperbolic product [BxS] and [BxS] loss rate. There was an OSAS-related gender dimorphism in degree of glucose control, with higher HbA1c (by 7.0 mmol/mol (+12%)) in OSAS [+] females, a mere 17% of whom reaching target (<7.0%) HbA1c (vs. 40% of OSAS [+] males; p 0.0272). There was also an OSAS-related gender dimorphism in apolipoprotein B100 level, higher by 15 mg/dL (+17%) in OSAS [+] females. As regards atherogenic indices, both the apoB100/apoA1 and the log(TG)/HDL-C ratios were sexually-dimorphic in relation to OSAS. Whereas prevalence of AITD was markedly higher in females regardless of OSAS, there was a marked and significant OSAS-related gender dimorphism in frequency of GAD65 antibodies positivity, higher by an absolute 21% (+793%) in OSAS [+] females (vs. OSAS [+] males); and by an absolute 17% (+335%) (vs. OSAS [−] females). There were opposite OSAS-related sexual dimorphisms in microangiopathy, with lesser and higher prevalence of retinopathy and polyneuropathy in females, respectively.

**Conclusion:** We observed significant OSAS-related sexual dimorphisms in GAD65 antibodies, polyneuropathy prevalence, atherogenic dyslipidemia indices [increased in females]; and in retinopathy prevalence, North-Caucasian ancestry, glucose control and TIA/stroke prevalence [lower in females]. These findings raise intriguing questions regarding the reciprocal pathophysiology between obstructive sleep disorders and T2DM.

Numbers represent the relative differences in mean values or proportions between males and females patients with and without OSAS (left columns), and the overall sexual dimorphism in OSAS patients (right column). The graph on the right side represents the male (black bars) and female (grey bars) components of the overall sexual dimorphism of OSAS.

## 1269

## Diabetic retinopathy and sleep apnoea: the Haute-Alsace health network experience

J. Wilhelm<sup>1</sup>, C. Iamandi<sup>2</sup>, A. Derragui<sup>3</sup>, P. Thannberger<sup>3</sup>, S. Moser<sup>1</sup>, P. Guiot<sup>4</sup>, R. Muller<sup>5</sup>, P. Lenoble<sup>6</sup>;

<sup>1</sup>Haute-Alsace Health Network, St Morand Hospital, Altkirch, <sup>2</sup>Department of Functional Explorations, St Morand Hospital, Altkirch, <sup>3</sup>Department of Internal Medicine and Diabetology, Altkirch, <sup>4</sup>AIR à Domicile' association, Mulhouse, <sup>5</sup>Department of Functional Explorations, Altkirch, <sup>6</sup>Department of Ophthalmology - Emile Muller Hospital, Mulhouse, France.

**Introduction:** Sleep apnoea is particularly common in patients with type 2 diabetes, and is not only associated with a higher risk of cardiovascular complications, but also with a higher risk of microangiopathy, especially retinopathy. The effect of treatment with continuous positive airway pressure on the evolution of retinopathy has not been documented to date.

**Materials and methods:** The Haute-Alsace Health Network developed a pluridisciplinary and multi-service platform designed to promote information, prevention, screening, therapeutic education, coordination and support for patients with diabetes. In particular, it includes screening for sleep apnoea and guiding its management. The prevalence of retinopathy was prospectively determined from January 2010, in 114 diabetic patients with sleep apnoea treated with continuous positive airway pressure, and in 641 diabetic patients without known sleep apnoea.

**Results:** In the literature, the prevalence of retinopathy appears to be 50% higher in diabetic patients with sleep apnoea. In the present study, the prevalence of retinopathy in diabetic patients with sleep apnoea treated with continuous positive airway pressure was similar to that of diabetic patients without known sleep apnoea. The effectiveness of noninvasive ventilation increased with the length of the treatment. These results were similar when patients were divided into subgroups according to their hemoglobin A1c levels and the duration of diabetes.

**Conclusion:** In the present study, treatment with continuous positive airway pressure was associated with a reduced risk of retinopathy in diabetic patients with sleep apnoea.

## 1270

## Obstructive sleep apnoea is independently associated with diabetic nephropathy and increased oxidative and nitrosative stress in patients with type 2 diabetes

M. Stevens<sup>1</sup>, A. Ali<sup>2</sup>, S. Begum<sup>3</sup>, K. Dubb<sup>1</sup>, S. Mughal<sup>4</sup>, B. Jose<sup>1</sup>, M.K. Piya<sup>1</sup>, A. Barnett<sup>1</sup>, A.A. Tahrani<sup>1</sup>;

<sup>1</sup>University of Birmingham, <sup>2</sup>University Hospital of Coventry and Warwickshire, Coventry, <sup>3</sup>Birmingham Heartlands Hospital, <sup>4</sup>Birmingham community PCT, UK.

**Background and aims:** Diabetic nephropathy (DN) causes significant morbidity and mortality. Understanding DN pathogenesis is essential to develop new therapies. Obstructive sleep apnoea (OSA) is prevalent in patients with type 2 diabetes (T2D). Since OSA and DN may share common oxidative stress and inflammatory mechanisms, we hypothesized that OSA is associated with DN in patients with T2D.

**Materials and methods:** Adults with T2D were recruited randomly from the diabetes clinic of two UK-based hospitals. Patients with known respiratory disorders (including OSA) and end-stage renal disease were excluded. DN was defined by eGFR of <60 ml/min/1.73m<sup>2</sup> or the presence of albuminuria (2 out of 3 early morning samples) after exclusion of other causes. OSA was assessed using home-based portable multi-channel respiratory device (Alice PDX, Philips Respironics, USA). OSA diagnosed when the apnoea-hypopnea index (AHI) was ≥5 events/hour (OSA+). Serum 3-nitrotyrosine (NT) (nM) and plasma lipid peroxide (LP) (μM/ml) were measured (n=102 samples) by commercial assays as markers of nitrosative and oxidative stress respectively.

**Results:** Two hundred and thirty four patients were included, 64.5% were OSA+ and 39.7% and 36.2% had DN and albuminuria respectively. OSA+ patients were older, more obese and had higher BP compared to those without OSA. DN (29.7% vs. 55.9%, p<0.001) and albuminuria (24.3% vs. 43.2%, p=0.007) prevalence were higher in OSA+ patients. OSA+ patients had lower eGFR (92.9 ± 25.2 vs. 82.4 ± 26.4, p=0.006). OSA+ remained independently associated with DN (OR 2.17, 95%CI 1.03-4.60, p=0.04) after adjusting (using logistic regression) for age, gender, ethnicity, BP, HbA1c, total cholesterol, triglycerides, HDL, diabetes duration, smoking, alcohol, BMI, and the use of insulin, anti-platelet, glucose-lowering, lipid-lowering and anti-hypertensive

treatments. In addition, time spent with oxygen saturation < 80% was an independent predictor of DN (OR 2.85, 95% CI 1.20–6.78,  $p=0.02$ ) and albuminuria (OR 2.74, 95% CI 1.16–6.48,  $p=0.02$ ) after adjustment as in the above mentioned model. OSA+ patients had higher NT (23.53 (16.67–36.07) vs. 15.49 (11.53–24.28),  $p=0.007$ ) and LP (18.39 (8.33–37.40) vs. 7.93 (0.81–22.76),  $p=0.014$ ) levels. NT levels correlated with measures of OSA severity and nocturnal hypoxemia. After adjustment as in the above mentioned model using linear regression, OSA remained independently associated with NT levels ( $p=0.003$ ). AHI ( $B=0.28$ ,  $p<0.001$ ), oxygen desaturation index ODI ( $B=0.27$ ,  $p<0.001$ ), and nadir nocturnal oxygen saturation ( $B=-0.33$ ,  $p=0.006$ ) were also independently associated with NT levels after adjustment. LP correlated significantly with measures of OSA severity and nocturnal hypoxemia severity. After adjustment for age, BMI and diabetes duration LP remained independently associated with ODI ( $r=0.221$ ,  $p=0.031$ ) and nadir nocturnal oxygen saturation ( $r=-0.220$ ,  $p=0.032$ ).

**Conclusion:** We describe a novel association between OSA and DN and nocturnal hypoxemia in patients with T2D and we have identified increased nitrosative and oxidative stress as possible underlying contributors to this association. The ability of OSA treatment to impact DN warrants determination.

# European Association for the Study of Diabetes

## EASD Executive Committee

President:	A.J.M. Boulton, UK (retires 2014)
Vice-President:	S. Del Prato I (retires 2014)
Vice-President:	F. Bosch, ES (retires 2012)
Honorary Secretary:	M. Walker, UK (retires 2013)
Honorary Treasurer:	M. Roden DE (retires 2014)
Chairman of the Postgraduate Education Committee:	C. Tack, NL (retires 2013)
Editor-in-Chief, DIABETOLOGIA:	J. Zierath, SE (retires 2013)

**EASD Council comprises of the Officers above and the following members:**

### Term Expiring 2012

J.-M. Boavida, Portugal  
C.-G. Östenson, Sweden  
A. Pfeiffer, Germany  
N. Wareham, UK

### Term Expiring 2013

F. Beguinot, Italy  
J. Dekker, Netherlands  
F. Karpe, UK  
V. Urbanavicius, Lithuania

### Term Expiring 2014

K. Birkeland, Norway  
J. Bodansky, UK  
C. Levy-Marchal, France  
P. Nawroth, Germany

The Past President, U. Smith, and the Secretary of the Postgraduate Education Committee, L. Czupryniak, are members of the Council ex officio.

### HONORARY AUDITORS

P. Diem, Switzerland (retires 2014); L. M. Gardete-Correia, Portugal (retires 2014)

### HONORARY MEMBERS

G. Alberti, UK; D. Andreani, IT; J.-P. Assal, CH; E. Cerasi, IL; O.-B. Crofford, USA; A. Czyzyk, PL; T. Deckert, DK; P. Freychet, FR; H. Keen, UK; E. Kohner, UK; P. Lefèbvre, BE; R. Luft, SE; C. Lurie, USA; Carl Erik Mogensen, DK; J. Nerup, DK; L. Orci, CH; G.M. Reaven, USA; J. Pirart, BE; S. Rahbar, USA; J. Roth, USA; E. Shafir, IL; D. Steiner, USA; R. Unger, USA; E. von Wasielowski, DE; W. Waldhäusl, AT; C.B. Wollheim CH; Paul Zimmet, AU

### GOLD MEMBERS

Astra Zeneca, Mölndal, Sweden; Bayer HealthCare, Berlin, Germany; Boehringer Ingelheim GmbH, Ingelheim, Germany; Bristol-Myers Squibb, Uxbridge, UK; Eli Lilly & Co., Indiana, USA; Janssen Pharmaceutical NV, Beerse, Belgium; LifeScan, Inc., High Wycombe, UK; Merck & Co. Inc., New Jersey, USA; Novartis Pharma AG, Basel, Switzerland; Novo Nordisk A/S, Bagsvaerd, Denmark; Pfizer Inc. New York, USA; Sanofi, Paris, France; Takeda, London, UK

### SILVER MEMBERS

Abbott Diabetes Care, Berks, UK; Arkay Europe, Amstelveen, Netherlands; C8 MediSensors, Inc. San Jose, USA; Daiichi Sankyo Europe GmbH, Munich, Germany; Roche Diagnostics GmbH, Mannheim, Germany

### ASSOCIATE MEMBERS

77 Elektronika Ltd., Budapest, Hungary; A. Menarini Diagnostics, Grassano, Italy; Amylin Europe Ltd., San Diego, USA; Becton Dickinson Europe, Pont-de-Claix, France; Dexcom Inc.
